855 (17)

THE
CANADIAN ENGINEER

ESTABLISHED 1893

Issued Weekly in the interests of the Civil, Mechanical, Structural, Electrical, Marine and Mining Engineer, the Surveyor, the Manufacturer, and the Contractor.

Index to Volume (16) 23

JANUARY-JUNE, (1909) 1912

The volume of editorial matter has increased to such an extent that it has been found necessary to issue indexes every six months. Henceforth a new index will appear in June and December.

BOOK REVIEWS.

Analysis of Metallurgical and Engineering Materials. H. Wysor. 810
Artistic Bridge Design. H. G. Tyrrell 686
Bandbook for Highway Engineers. W. G. Harger and E. A. Bonney. 688
Bleaching and Dyeing of Vegetable, Fibrous Material. J. Hubner 933
Boundaries and Landmarks. A. C. Mulford 932
Building Stones and Clay-Products. Heinrich Ries 932
Central Heating Station. B. T. Gifford 688
Concrete Highways 688
Concrete Workers Reference Books. A. A. Houghton 398
Cooking of Coal at Low Temperature, with a Preliminary Study of the By-products. S. W. Parr and H. L. Olin 811
Design of Mine Structures, The. M. S. Ketchum 130
Design of Steel Mill Buildings. M. S. Ketchum 689
Dewey Decimal System of Classification Applied to the Engineering Industries, An Extension of the. By L. P. Brackenridge and G. A. Goodenough 930
Diary of a Roundhouse Foreman. T. S. Reilly 398
Differential and Integral Calculus. Lorrain S. Hurlburt 812
Elements of Drawing. G. F. Blessing and L. A. Darling 811
Energy and Velocity Diagrams of Large Gas Engines. P. L. Joslyn 688
Engineering Directory, 1912 131
Engineering for Land Drainage. C. G. Elliott 813
Farm Gas Engines, H. R. Brate 131
Fourth National Conference Proceedings 932
Heat Treatment of Tool Steel. H. Brearly 130
Indicator Handbook, Part 2. Chas. N. Pickworth 931
Light: Its Use and Misuse 812
Machine Design. H. D. Hess 689
Materials and Construction. J. A. Pratt 531

*Illustrated.

Materials Used in Sizing. W. F. A. Ermen 688
Measurement of High Temperatures. Burgess and Le Chotelier 130
"Mechanical World" Pocket Diary and Year Book for 1913 812
Metallography of Iron and Steel. T. R. Loudon and A. Sauveur 810
Metallography of Iron and Steel. Albert Sauveur 686
Metropolitan Water Board. A. C. Houston 398
Modern Gasoline Automobile, its Construction, Operation, Maintenance and Repair. V. M. Pagé... 812
Modern Illumination Theory and Practice. H. C. Horstmann and V. H. Tousley 131
Modern Organization. Chas. DeLano Hine 687
Modern Sanitary Engineering. G. Thomson 813
Official Good Roads Year Book of the United States. J. E. Pennybacker 812
Preliminary Studies in Bridge Design. Reg. Ryves 531
Principles of Structural Mechanics. P. J. Waldram 130
Problems in Engineering. S. G. Turner 131
Properties and Design of Reinforced Concrete. Nathaniel Martin 812
Pumping and Water Power. F. A. Bradley 399
Raising the Wreck of the U. S. Battleship "Maine" 531
Reinforced Concrete Construction. M. T. Cannell 130
Reinforced Concrete Construction. G. A. Hool 398
Reference Book for Statistical Calculations. F. Ruff 398
Smoley's Tables. C. Smoley 933
Some Facts About Treating Railroad Ties. W. F. Goltra 812
Steel Sheet Piling Tables and Data on the Properties and Uses of Sections 811
Street Paving and Paving Material. G. W. Tillson 932
Strength of Materials. M. Merriman 811
Successful Homes and How to Build Them. Chas. E. White 932
Text Book of Physics 689
Text Book on Roads and Pavements. F. T. Spalding 933
Theory of Structures. R. W. Angus 687
Transit Theodolite, and Other Instruments Mechanically Considered. H. W. Valle 131
Transmission Line Construction. R. A. Lundquist 930
Treatise on the Design and Construction of Roofs. R. C. Ricker 931
Tunneling: A Practical Treatise. Chas. Prelini 688
Water Supply and Drainage. C. E. Housden 931
Webster's New International Dictionary 399

The Canadian Engineer

An Engineering Weekly

DESCRIPTION OF REINFORCED CONCRETE ARCH OVER CURRENT RIVER, CITY OF PORT ARTHUR, ONTARIO.

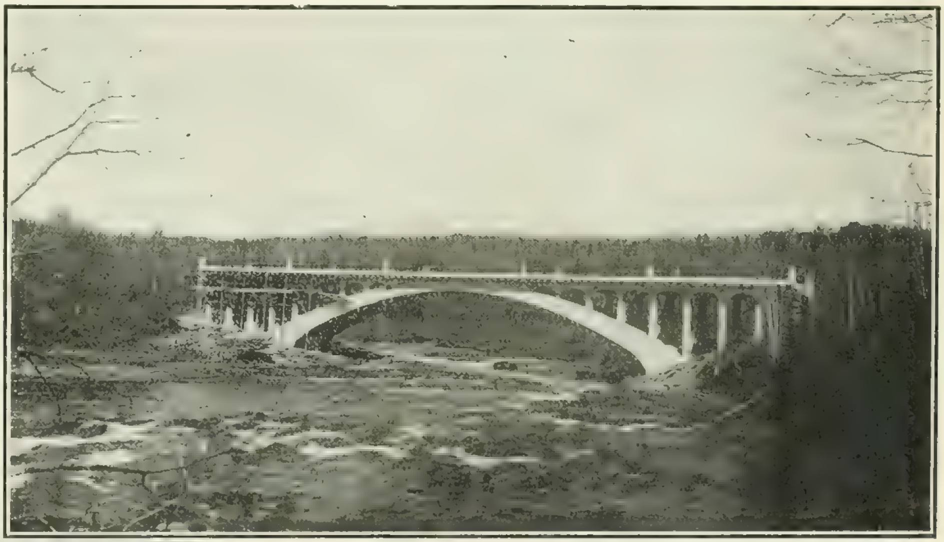
By L M. JONES, A.M. CAN. SOC. C.E., City Engineer.

The bridge to be described is situated on the line of the Black Bay Road, where it crosses Current River. This road is a government highway, and was constructed and used during the time of the construction of the Canadian Pacific Railway for hauling supplies.

The waters of Current River have been developed by the city of Port Arthur for the generating of power which is being used in the operation of its various public utilities. In connection with the development of this river there have been a number of dams constructed for the purpose of storing water and the proper regulating of the flow of the river.

On the night of May 27th, 1908, the dam at the reservoir, known as Paquette, broke away, the water carrying everything in its path, and among the structures carried away was the bridge over the river at the Black Bay Road.

The rebuilding of this bridge was delayed for some time, and a temporary crossing to the northerly side of the river was constructed about a mile down the stream, which served the purpose until the Cumberland Street bridges, previously described, were completed.



View Showing the Completed Structure.

View of Old Bridge Carried Away by Flood.

As stated before, the Black Bay Road is a government road, and the city council of Port Arthur felt that a request should be made to the government for some financial aid in the rebuilding of the bridge, the type of bridge to be more permanent than the one which was destroyed by the flood. Consequently, plans were prepared which, together with a water color sketch of the proposed bridge and surroundings, were sent to the Honorable Minister of Public Works, with the result that the city received a grant of $5,000 towards the erection of the new bridge.

General.—The character of the river banks at the location of the bridge were admirably suited to an arch of long span, the banks being composed of solid rock, which, while being a little seamy and soft at the surface, proved to be good, solid trap rock a few feet down.

As will be seen from the sketches, the elevation of the old bridge was considerably lower than that adopted for the new one. Some opposition was met with in this connection, it being feared that the bridge was too high, but as this was a proposed route for future street car traffic, and the grades of the approaches being quite satisfactory for such traffic, the opposition was overcome, and now all are highly pleased with the results.

The type of bridge selected is a two-rib, reinforced concrete arch of one hundred and thirty foot clear span
deck is supported upon reinforced concrete col
inches square; the deck extending approxima
beyond the back of the abutment on each sid
This extension was designed beyond the bac

ment so that the toe of the embankment would be well away from the action of the water. It also permits the use of a lighter structure, as there is no earth fill to add weight to the dead load.

Built in this manner, there would be no need of rip rapping the slopes, and the necessity of wing-walls and retaining walls, which, at their best are unsightly, was obviated. This type of construction also adds to the graceful appearance of the structure, and its cost, as compared with the fill required to replace it, rip rapping, and wing-walls is not much greater. It might be well to add that about an eighth of a mile down stream from the bridge is an artificial lake, while upstream from the bridge, just a few hundred feet, the river turns practically ninety degrees northward, the farthest bank from the bridge being a tree-covered bluff about one hundred and fifty feet high, which forms a good back ground for the bridge, viewing it from the reservoir. It was felt, therefore, that this type of bridge would blend with the surroundings better than having spandrel walls, wing-walls, etc., for retaining the embankment.

The intrados and extrados were both designed as para[illegible] curves, the intrados being increased at the abutment [illegible]

View Showing Covering for Finishing Walks and Surfaces During Cold Weather.

View Showing Formation of Rock Foundations.

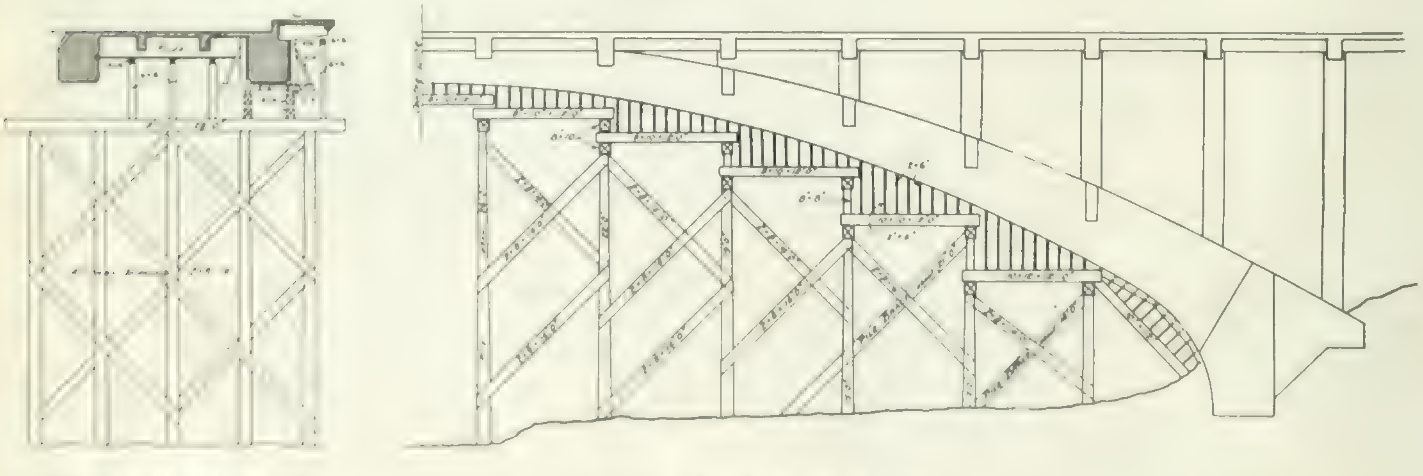
Between the ribs at the abutment a curtain wall was constructed connecting the ribs, which served as a strut and improved the appearance of the abutments from the river side.

The deck of the bridge is made of the beam and slab type, the slab being six inches in thickness. The deck was three inches higher at the centre of the bridge than at the ends, this being done to afford proper drainage of water to the outlets located at various points. The effect of this difference in height is not noticeable to the eye.

The sidewalks, which are five feet wide, are supported by cantilever beams from the columns and ribs. It will be observed that in order to obtain sufficient concrete section for the cantilevers, without allowing beams to go below the extrados of the arch, the connection between slab and curb was designed with a fillet, built in monolith, at the intersection.

The width of the bridge between curbs is sixteen feet. This does not give sufficient room for car and vehicular traffic at the same time, but as neither traffic of this kind will be heavy for the present, the width will be fully adequate for the conditions. However, when the traffic has grown to such an extent that a wider bridge will be necessary, the intention is to take off one of the sidewalks and add other ribs, thus making the roadway double the present width. From outside to outside of sidewalks the width is 26 ft. 0 in.

The railing consists of a two and one-half inch pipe, and over every fourth column a concrete post is placed into which the pipe is inserted in a loose joint.



CROSS SECTION

DETAIL OF FALSEWORK

Sketch Showing Details of Falsework.

The difference in elevation of the river banks at the approximate ground level is about twenty-four feet. The natural approach to the bridge on the southerly end is very steep, so that it was necessary to make an excavation of considerable extent to secure a five per cent. grade descending to the bridge The material, however, was necessary to make the fill on the northerly end of the bridge. The roadway descends on a two per cent. grade from the bridge on this end.

Owing to delays in the passing of the necessary money by-laws, etc., the commencement of the work was put off until late in the season. The grant of $5,000 which the government had made towards the construction of the bridge was included in the estimates for 1911, so that when everything was considered it was thought best to build the bridge in the same year. The contract was let on August 25th, and work commenced three days later; the bridge proper was completed on November 10th.

Upon enquiring, I understand that this arch, at the time of its completion, was the longest span of its type in Canada.

Design.—In the design of the bridge the calculations were based upon the following:

Ratio of modulus of elasticity of steel to that of concrete, 15.

Allowable working stress of steel in tension = 16,000 lbs. per square inch.

Allowable working stress for concrete:

(1) The extreme fibre, 750 pounds per sq. in.
(2) Direct compression, 600 pounds per sq. in.
(3) Shear, 50 pounds per sq. in.

The loads figured on were:

Live load, a thirty-ton street car, and an additional live load of 100 pounds per square foot, and a fill of gravel of approximately fourteen inches; impace figured at 50 per cent. of the live load.

Cement.—The cement used in the construction of the bridge was "Sun" brand Canadian Portland cement, tested to meet the requirements of the Canadian Society of Civil Engineers' specifications.

Sand.—The sand used was ordinary bank sand, coarse grained and sharp, containing a very small percentage of loam.

View Showing Arrangement of Plant and Runways.

View Showing Deck Forms Ready for Concrete.

Gravel.—Gravel was used in place of crushed rock, owing to the difficulty of obtaining the latter. The gravel used was lake shore gravel, similar to that previously described, ranging in size from that of a pea to one which will pass through a one-inch ring.

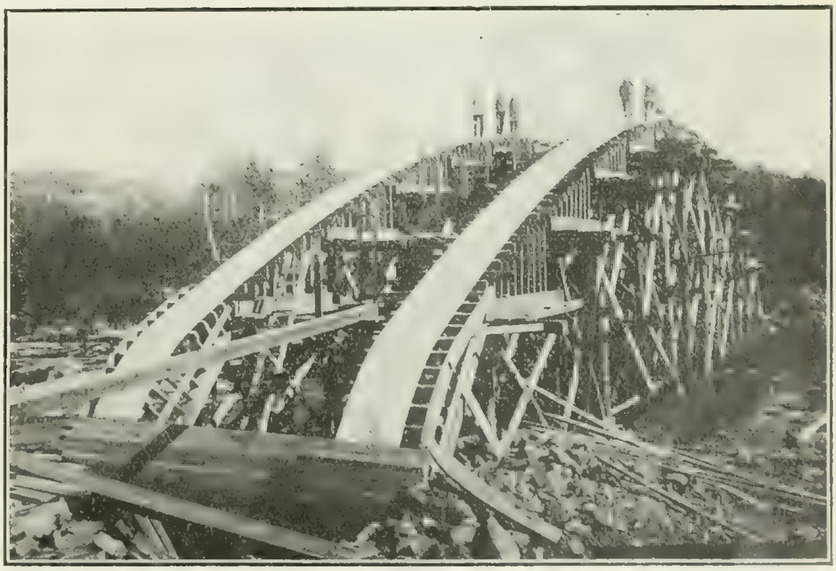
Concrete.—The concrete was all machine-mixed in the proportions of the above material as follows:

Abutments next to rock, 1:2:4; in mass, 1:3:5; ribs and struts, 1:2:4; columns, beams and slabs, 1:1½:3.

A wet mixture was used, being well spaded and worked at faces of forms, so that when the forms were removed the surface finish had scarcely a scar upon it.

In the view will be seen the arrangement of the mixing plant. All the material was delivered on the bluff and the mixer was set below, so that the charging of same was made particularly easy. A long runway was constructed, as shown, and the concrete deposited in place by means of a chute.

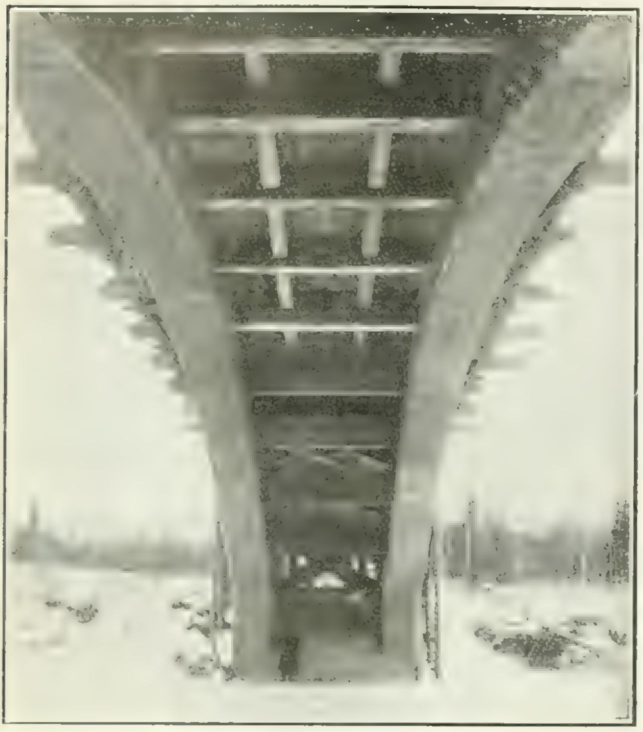
Reinforcing Steel.—The steel used in the construction is the "Kahn" system of reinforcing, furnished by the Trussed Concrete Steel Company, of Walkerville, and was purchased direct by the city and delivered f.o.b., the site of Legisla-



View Showing Forms for Ribs Ready to Put Forms for Slides In Place.

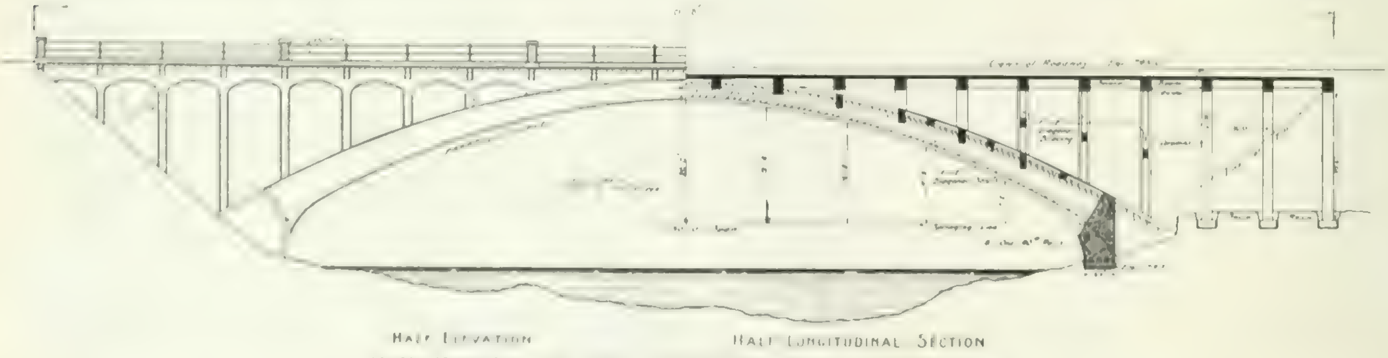
Construction.—After the necessary rock [illegible] wment Act a
for the foundations, the falsework f[illegible] nt of a Board
was commenced. The sketch [illegible] be to deal with
[illegible] y necessary to

ment of supports and formwork. The upright posts were taken out of the woods a quarter of a mile from the site of the works, and served the purpose equally as well as squared timber. After the concrete in ribs was poured it was found that the settlement in the forms at the crown of the ribs was two-hundredths of a foot. When the ribs and column footings were constructed the form work for the columns and deck were commenced, and no further concrete work was done until the forms were completed.



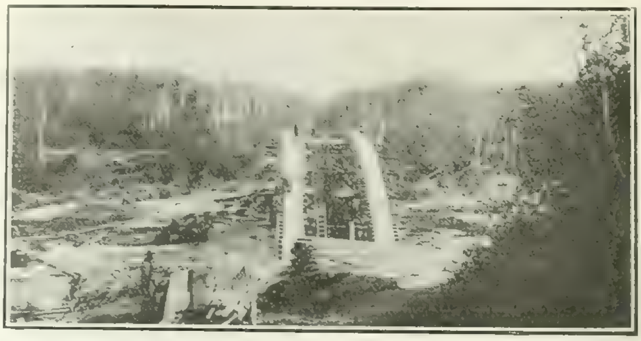
Under Side of Ribs and Deck.

In the construction of the ribs the concrete in the abutments of each rib was brought up to the chamfer and there squared off at right angles to the thrust line. Then the construction of the balance of the ribs was commenced from the same end of the two ribs, also struts and diagonals being brought up at the same time for a distance of fifteen feet along the ribs, then the same amount of work was performed on the other end. When these two first sections were completed an uplift was noticed in the forms at the crown of about eighteen-hundredths of a foot. It was feared that this [illegible] [illegible], and if it became worse it was decided that [illegible] the rib at the crown would be built to [illegible] equally at the haunches. However, this [illegible], as no further movement occurred and gradually, as the work of pouring the ribs proceeded, the framework settled back to its original location.

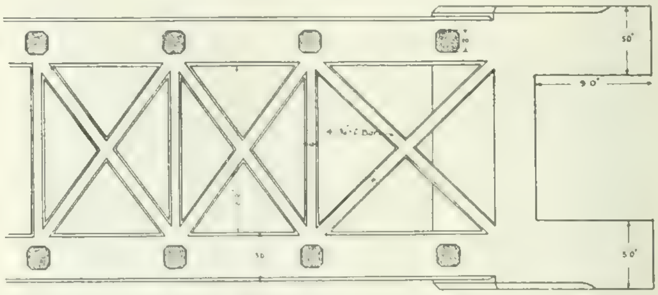


Half Elevation and Half Longitudinal Section of Bridge.

The centres under the ribs were not removed for thirty-nine days after the pouring of the concrete. Observations taken before and after their removal revealed no settlement in the bridge whatever. The forms were taken off the ribs entirely at the same time, but owing to the lateness of the season and the cold weather the forms on the columns and deck were left on all winter. It will be interesting to note that most of the surfaced finishing of sidewalks, curbs, concrete posts, etc., was done under canvas, as shown in the view. This arrangement was heated with two or three stoves, which made the performance of the work possible under the existing weather conditions.



View Showing Formwork of Ribs and General Surroundings.



Diagonal Struts and "U" Abutment.

The materials for doing the work were heated by the ordinary methods. Upon the completion of the work, the exposed surfaces of the concrete were given a waterproofing coat of "Drywall," which has proved very satisfactory on other concrete structures built here.

There were three bids received for the carrying out of the work, the successful tenderers being Messrs. Seaman and Penniman, of Fort William. This firm has a wide practice in this district, and deserve to be complimented upon the successful manner in which they carried out the construction. Also, for completing the work in the short time given them.

Costs.

Lump sum price, as per tender		$11,000.00
Concrete in diagonal members, not included in original plan	16.5 cu. yds.	
Changing thickness of floor from 4 in. to 6 in.	23.0 cu. yds.	
Additional length of the columns	10.4 cu. yds.	
	49.9 cu. yds.	
49.9 cu. yds. at $19		948.10
Additional concrete in the abutments, 48.0 cu. yds. at $11.50		552.00
		$12,500.10

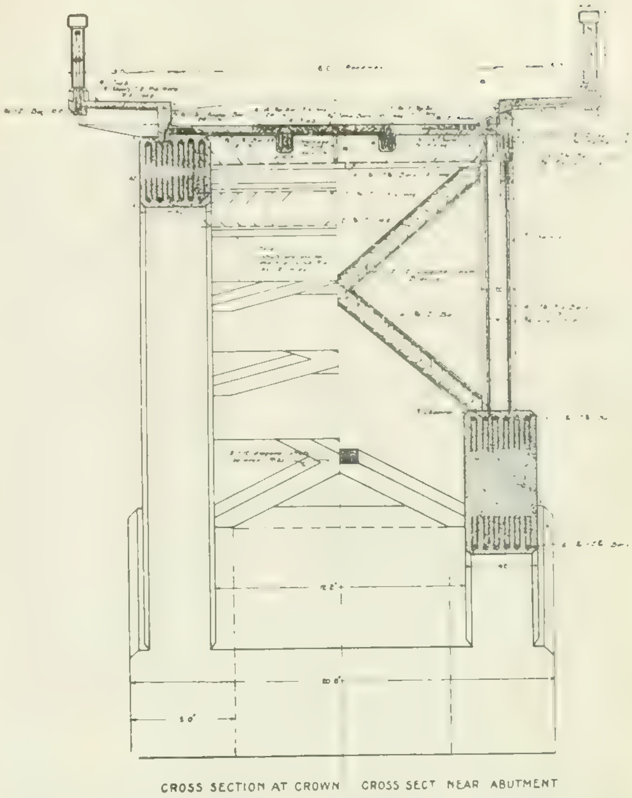
Hand Rail Post Details.

The design and supervision of construction of the bridge was carried out by the city engineer's department, Mr. E. Elliott Henderson, assistant city engineer, preparing plans of the design, with the assistance of Mr. N. V. Wrigley. Mr. Wrigley was also inspector on the construction, and for the successful carrying out of the work they deserve a great deal of the credit.



Sections Through Bridge at Crown and Near Abutments.

THE NEW CANADIAN PACIFIC RAILWAY HOTEL IN VANCOUVER.

Contracts have been awarded for the erection of the new C.P.R. hotel in Vancouver. The work is complicated by the fact that the hotel will be erected on the site of the present building, the business of which will be carried on throughout the operations. The old building will be underpinned, and the excavations for the foundations, as well as the foundations themselves, will be completed before the actual work of demolition of the superstructure is commenced. As soon as the foundations are finished, the construction of the wing next to Opera House Lane will be rushed. This will be used in conjunction with the old building for hotel business, and as soon as the ground floor of the main wing is finished, it will be covered with a temporary roof and used. Then the old building will be torn down.

The main block will be of ten stories, and provision is made for extending the building to fifteen or sixteen stories, the matter now being the subject of negotiations with the civic authorities. The building is to be fitted up in the most sumptuous style. For instance, in the ladies' loggia on the Georgia Street side, prominent artists will be set to work to paint the walls in the Italian Renaissance style. The dining-room is planned to be the finest on the continent no less—and there will be a concert room having a seating capacity of 600, which may be used for a ballroom. On Granville Street there will be six first-class merchant shops, and a bar one hundred feet long. There will be 600 rooms in the building when it is of six stories, and 900 wh[illegible] is completed to its full height of 16 stories. Th[illegible] and power plant, for which the contract h[illegible] awarded, will cost $1,500,000.

ry necessary to

THE ADMINISTRATION OF THE HIGHWAY IMPROVEMENT VOTE IN SASKATCHEWAN.

The following is an abstract of a bulletin issued by Mr. A. J. McPherson, the Chairman of the Board of Highway Commissioners of Saskatchewan.

No more distinctive features serves to mark modern conditions as compared with the past than the great development in transportation facilities. Immense sums are spent in railroad building and the highest skill employed in devising ways of improving methods in connection with railroads. The same applies to water transportation, so that within the last centry distance has been comparatively annihilated.

While it is true that transportation development has been very far-reaching in its effects and has changed the whole character of modern civilization, the development regarding highway construction in many countries where this change has taken place has not advanced to any proportionate extent, especially in rural districts. While the cost of transportation has been reduced by these modern methods to a very small amount per ton mile the cost of hauling agricultural products to the markets which have now become the towns along the railroad lines, still remains about 25 to 30 cents per ton mile. A direct saving in cost of this delivery to the markets can be effected by constructing good roads and under present conditions every cent of this saving would go into the pockets of the people.

It may be said that farmers would not gain anything by a quicker delivery to market and that they will make but a definite number of trips per day in any case and that they have to have the necessary horses for farm work so that they would not save anything by improving the roads. This is not the case, however, as farming in these days has become as systematic as any other line of business and successful farmers make every effort count the same as other successful men. Anything that will reduce the effort required to produce results such as the improvement of roads to market means an advantage in making a success of the business.

It is only a question of how much traffic exists or will be created on any road to determine the expenditure that would be warranted in improving it.

Land values adjoining are increased by the construction of good roads, land being of little intrinsic value unless the products therefrom can be transported to market in an economical manner. It is only necessary to examine the drop in land values as the distance from markets increases to realize that anything that will make them more accessible will increase the value of land. In many sections, at certain times of the year, the condition of the roads prohibits leaving the farm and the people on the farms through this lose interest in current events, become dissatisfied and are not in a position to carry on their business with an enthusiasm which is necessary to make a success of it. Bad roads react in this way so as to affect all departments of country life and im- [illegible]

General Policy.—[illegible] Department of Public Works has spent annually on the im- [illegible]

In 1906 when it was decided to carry out an improvement in some certain locality one of the local residents who was known to have ability in that kind of work was appointed to organize the local labor and do the work. The result of this system was that the improvement of roads was always considered a secondary matter and the work was attended to or not, depending on whether the appointee found time to undertake it after attending to his own business and as a result, in many cases the work was not done or the money was spent at a season of the year when the most value could not be obtained for the amount expended.

In 1907 the system of administering the vote was changed with the idea of overcoming the defects observable during 1906. Instead of local men being appointed the best men that could be selected from the list of foremen employed in 1906 were appointed as road foremen to act during the full season and to go around from place to place where it was decided to make improvements, organize the local labor and see that the work was properly done. A great improvement was noticed under this system as the season advanced. These foremen rapidly became expert at laying out the work and directing how it should be done, wasted less in misdirected efforts and the quality and style of the work throughout the province became more uniform.

The same policy with slight modifications to meet changing conditions in different years and in different parts of the country was followed in 1908 and 1909 and regarding a large part of the expenditure on roads up to the present time. Conferences of these foremen have been held, many manuals and publications regarding road matters have been distributed to them and to the local authorities and a force of skilful inspectors has been constantly kept visiting them during the progress of their work, the result being that we have now a large number of men scattered over the province in all its parts who have an excellent idea of road building and of what is necessary in this regard to meet varying local conditions.

In 1910 this policy of education was extended more directly than heretofore to the local authorities by asking them to work out their own problems and sending what assistance was possible to them in doing so. This was effected by making grants under regulations approved by the Lieutenant Governor in Council to all municipalities which had completed their organization under the Rural Municipality Act whereby the work had to conform to a certain standard and they had to collect certain information, thus ensuring a certain amount of [illegible] would be entitled to the grant. This system has produced a good effect and has given satisfaction where properly worked out.

Classification of Roads.—In determining the location of the roads where grants would be warranted the provincial authorities recognized that roads should be classified as to their importance. Those having the heaviest traffic and on which traffic from a large area would develop were classed as main roads and were considered of a provincial nature and therefore would warrant the assistance of the provincial authorities in improving and maintaining, and those which served but a small area and sparse traffic were considered local and should therefore be attended to by the local authorities.

In a new country such as Saskatchewan and where [illegible] improvements [illegible] beyond the [illegible] located on purely [illegible] long grades across marshes and sloughs, side hill roads across ravines, etc., come in this class and the provincial authorities could [illegible] from provincial funds. As a result practically all bridges of 20-ft. span and over and many culverts and small bridges have been constructed by the provincial government and in most cases the maintenance has also devolved on the provincial authorities.

Capital and Current Expenditure.—A large number of bridges deemed advisable to construct as steel bridges on concrete foundations or of reinforced concrete have been treated as permanent structures and paid for out of capital but all the road work and the majority of the bridge work has up to the present been met from the current revenue of the province. Many of these improvements are an undoubted permanent asset to the province and should be considered as capital and treated accordingly, while a great deal of work such as grading, minor improvements in filling holes, maintenance of bridges, etc., the result of which will disappear in a few years should properly be met from the current revenue.

It has been brought to the attention of the government from various sources that there is a necessity of a more rapid development regarding works which are of a more purely capital nature, and with this object in view provision has been made by legislation for meeting the cost of these improvements to the extent of $5,000,000 and it is the intention to proceed as fast as is considered advisable consistent with economy, efficiency and the resources available in the way of labor and equipment, with the prosecution of the work. This will be additional to the ordinary expenditures undertaken as in the past, but the latter will be made to cover works of a more purely maintenance character with the tendency constantly existent to spend the money in such a way as to produce permanent results.

The principle of making improvements of a permanent nature from capital expenditures has been recognized by the Legislature as regards local affairs in that The Rural Municipality Act and the Cities and Towns Act, which serve as the charters of these institutions, make provision for the issuing of debentures to cover the cost of improvements of a similar nature to be repaid within the life of the improvements.

The policy of enlisting the interest and co-operation of the local authorities in various ways and the distribution of the expenditure in accordance with principles as already outlined regarding works of a provincial nature, main roads, large bridges, etc., will be followed.

A larger sum will be available for the construction of permanent bridges and the usual vote will be supplemented by an amount sufficient to ensure that when advisable they will be constructed of steel, concrete and reinforced concrete instead of wooden structures which have a life of seven or eight years at most before they become of questionable strength.

Road Laws and Administration.—The laws relating to the construction and maintenance of public roads vary in different countries, each system being the outgrowth of many conditions peculiar to each country. Road building must vary to suit climate, physical conditions, density of population, character of traffic, etc.

When the construction of steam railways became common throughout civilization, attention was somewhat diverted from the building of common roads, but in recent years in all the most advanced countries the question of pubilc roads is receiving a great deal of attention and large sums are being expended theron.

A study of the laws and the methods of administration in the countries that are most noted for their progressive ideas on road building will show that some features are common to all, and it would almost seem that success need not be looked for unless those features receive attention.

A study of methods as adopted by progressive countries shows that it is hopeless to expect good road systems by depending on local municipal efforts. Roads are usually classified according to their importance and money is raised somewhat proportionate to the interest of the various authorities, state, provincial or local. Local authorities while having an interest in all the roads are not expected to meet the cost of constructing and maintaining important roads on which the traffic cannot be considered local and which therefore require proportionately heavier expenditure to keep in first class shape. A special effort and heavy expenditure is necessary to construct main roads and thereafter constant attention must be given to maintain them. In some cases men are constantly employed and devote their whole attention to the care and maintenance of main roads. In other cases the state or provincial authorities interest themselves in the construction while the maintenance is attended to by the local authorities. It has been shown to be folly to go to great expense in constructing good roads and then through neglect to allow them to get in bad repair. It is absolutely necessary that roads should receive almost constant attention after construction to keep them in first class shape, this being a case where "a stitch in time saves nine," without a doubt. The local authorities are in a better position to give this constant attention than the provincial authorities, being constantly on the ground, as it were, and they should recognize that this duty devolves on them.

Most countries where successful road systems have been built up maintain a central bureau for the collection and distribution of information, conducting experiments and generally acting in the advisory capacity regarding all phases of road work. Highway development in Saskatchewan has evolved naturally in accord with many of the principles outlined above and the present step being taken to provide for the construction of important improvements under capital account is entirely in accord with successful methods adopted elsewhere. These principles will be taken into consideration in the administration of any funds available for road improvement and methods worked out as seem best to suit the merits of the varying conditions throughout the province.

Class of Roads to be Built.—Up to the present there are very few places in the province where anything more than improvements to make the best possible earth road are undertaken and it is only where gravel is easily available that short stretches of gravelled road have been constructed. In some of the older towns their main streets are gravelled and are kept in very good condition, but as far as the country roads are concerned almost without exception they are simply earth roads.

There are many places throughout the province where the country has developed to a high degree and where in order to be consistent with conditions some better form of road than an earth road is wanted.

Settlement in other places has taken place rapidly, with the result that the necessary attention to the roads has not been possible and many obstructions exist and long stretches of almost or at times impassable roads prevent ready access to markets. The standard of road to be aimed at must necessarily, therefore, vary for different localities, but it is exceedingly advisable that as high a standard as possible should be set. In some localities gravel and broken stone roads should be constructed, while in others the removal or overcoming of obstructions and the construction of the best earth road possible is immediately advisable with the possibility of a better grade of construction in the near future kept constantly in view.

Co-operation of Municipalities.—In order to ensure that the necessary consideration be given the subject the [illegible] ound that
ture has made provision in The Highway Improv[illegible] us check the
copy of which is appended for the appointme[illegible] al taps, and
of Highway Commissioners whose duty it will [illegible] flow would be
the merits of the cases as they arise. It is ve[illegible] curacy in the

ensure success that the local authorities co-operate with the board in carrying out the work in accordance with the general policy above outlined. The classification of roads and the development of the system, the standard of construction and the attainment of that standard as the work proceeds, depends to a great extent on the consideration that will be given by them.

During 1910 and 1911 many of the rural municipalities have taken into consideration the roads throughout their districts that should be considered as main roads and as such entitled to have the expenditure of provincial funds in their construction and plans have been prepared showing the roads that have been decided on in this way. Municipalities will be asked to give further consideration to this matter with the object of building up complete systems of main roads through the extension of those already undertaken and the addition of connecting roads from municipality to municipality.

Municipalities should consult with adjoining municipalities as to the most advisable main roads to improve to become part of a road system that will serve the territory and the board will give every consideration to the findings of such deliberations when placed before them. Proper methods of carrying on the work will have to be evolved and such methods decided on as seem to best suit the circumstances and the local authorities can give valuable information in this regard.

What should be decided on is the most efficient and economical method and the one that will be most certain of producing desired results.

Of the latter sum a part will be used to construct permanent concrete and steel bridges, thus supplementing the vote made otherwise for this purpose during each of the last few years.

The foregoing will be sufficient to give an idea of the situation as it exists at present and an outline of the policy regarding improvements.

A short review of the matter under consideration may be set out as follows:

The government is pledged to spend $5,000,000, $1,500,000 of which it is proposed to spend in 1912.

This will be spent on improvements as follows:

1. Main roads to be decided after consultation with municipalities.

2. Main roads out of organized districts.

3. Large works such as bridges, heavy fills, side hill grades, etc., beyond the means of local authorities although not on the main roads.

The methods of carrying out the work may be classified as follows:—

1.—**Road Improvements.**—As grants to municipalities. By Highway Commission day labor. By contracts from municipalities. By contracts from the Highway Commission.

2. **Bridges.**—By contract. By Highway Commission day labor.

In addition to this the Highway Commission will investigate methods of [illegible] that may seem to offer a solution for peculiar difficulties and will distribute information to those interested that will tend to raise the standard of the work. It will be in a position to give advice wherever needed [illegible] in the place of the [illegible] of the local authorities.

[illegible]

FLOOR AREA UNIT AS A BASIS FOR ESTIMATING WATER CONSUMPTION.*

By William W. Brush.†

In 1908 the writer was placed in charge of the general design of the delivery system to carry to the five boroughs of Greater New York the 500,000,000 gallons per day which would eventually be available from the Catskill watersheds, this work being carried on by the Board of Water Supply. Studies in connection with the design of this system required a determination of the existing consumption in each borough, and in sub-divisions of each borough, as well as an estimate of probable future growth in consumption.

It was found that the measurements of flow that had been made were not sufficient in extent to give a fair basis for estimating the present consumption in the various sections of the city, and that a per capita basis for consumption was practically useless for this purpose for the borough of Manhattan, due to the fact that large areas are wholly devoted to office buildings, manufacturing and other business purposes; and also due to the rapid changes going on in the elimination of buildings previously used for residences and the substitution of office buildings, lofts and factories.

While the water consumption of both large and small communities is generally expressed as the average amount supplied "per capita," this unit is used more on account of its convenience than for its usefulness as a basis for comparison of consumption in different towns and cities. In examinations made of the per capita consumption in different sections of large cities, variations of several hundred per cent. have been shown. The highest consumption is generally found in the highest class apartment houses, and the lowest consumption in the lowest class of tenements.

To carry out the work required to satisfy factory design the Catskill delivery system some unit of consumption was necessary that did not vary to the extent of the per capita unit and that could be applied to business as well as residential sections. An investigation of the available data on which to estimate future as well as present consumption showed that the area occupied by buildings would be the fundamental basis for future consumption, especially in the borough of Manhattan, and that, other things being equal, the amount of water used in any buildings would be dependent upon the ground area covered and the number of stories in height. It was, therefore, decided to study the use of the floor area unit as a basis for estimating consumption. The floor area was to be determined by multiplying the ground area of a building by the number of stories, allowing one additional story for basement or cellar. One thousand square feet of floor area was found to be a convenient unit and one that would give a resultant consumption averaging about three times that figured on a per capita basis.

To determine the present use of water per unit of floor area, typical buildings were selected in which the supply was measured by meters, and the resultant consumption determined. There were also available measurements of various districts in Manhattan, Brooklyn and the Bronx, which were made by use of the pitometer during waste investigations carried on in 1902-03. Table I. gives the results of these measurements, as well as those taken in 1911. A reduction in consumption in 1911 of about 15 per cent.

---

[*] Abstract of paper read before American Waterworks Association at thirty-second annual convention, Louisville, Ky., June 3-8, 1912.

[†] Deputy Chief Engineer, Department of Water Supply, Gas and Electricity, New York City

was effected by house to house inspection, while in 1902 no work had been done on water waste.

Table I.—Water Consumption in Various Districts of New York.

No. of District.	Characteristics of Occupancy.	Consumption M. G. D.	Population Resident.	Consumption Per Capita.
	Gaugings, 1902-03.			
1	Large hotels, high-class residences	1.87	8,396	223
2	East side tenements	1.44	38,906	37
3	East side tenements	5.40	90,000	60
6	Residence and high-class apartments	0.76	10,164	75
8	Business, office buildings, waterfront, shipping	9.45	11,000	860
9	First-class apartments and hotels	1.37	8,872	154
10*	East side tenements, some waterfront	20.20	218,023	93*
11	Uptown residences and medium class apartments	4.89	4,380	112
12	Upper east side tenements, waterfront, power houses and breweries	2.75	39,969	69
	Gaugings, 1911.			
1a	East side tenements, some waterfront (same as District No. 10)	11.44	230,500	50
2a	All classes	29.48	204,557	144
3a	High-class apartments and residences	22.18	186,990	118
4a	High-class apartments, residences and tenements	12.74	138,800	92
5a	East side tenements, and waterfront	8.28	84,580	98
6a	High-class apartments, residences, tenements and waterfront	14.82	173,000	86
7a	All classes	13.38	169,100	79
8a	All classes	13.66	209,393	65

---

* An error was later discovered in the measurement of flow in this district, which reduced the consumption as given by about 50 per cent.

With a variation in the per capita consumption of from 37 to 860 gallons daily, it was evident that it would be difficult to apply a per capita basis to different sections of the city to determine the consumption in such sections.

It was found upon examination that with the exception of those buildings where the consumption of water would be unusually high, such as hotels, laundries, ice plants, etc., the use of water per thousand square feet of floor area was from 150 to 300 gallons per day. This covered only those buildings used for business purposes, as under the rules of the Water Department, meters are not required in buildings used for residences. It was anticipated that apartments of the higher class would show a somewhat larger use of water per unit of floor area than would the tenement class, and that both would show a larger use than private residences.

The first computations made of consumption in districts which covered several blocks, included a high-class apartment house and hotel section in the vicinity of 80th Street, on the west side, and a low-class tenement section on the east side in the vicinity of 80th Street. The per capita consumption in these two districts was 154 gallons per day and 37 gallons per day, respectively, the high-class apartment district therefore showing a consumption, on per capita basis, of over 400 per cent. of that shown for the tenement house district. On the floor area basis, the figures for these two districts were 181 and 179 gallons per day per 1,000 sq. ft. respectively, or a variation of less than 2 per cent. between the two districts. While this close agreement in consumption for the two districts was a coincidence, it strikingly illustrates the uniformity obtained from the floor area basis as compared with the per capita basis in two residential districts where the character of population varied widely. As further studies showed the floor area basis to be a practical one, it was applied generally to the borough of Manhattan. The ground area was scaled from the atlas, and this area multiplied by the number of stories, the buildings being grouped as far as possible to reduce the labor. After the entire area of the borough of Manhattan had been determined the average consumption was computed and proved to be about 300 gallons per 1,000 sq. ft.

To determine the prospective use of water in the borough of Manhattan, the area available for building was determined, eliminating street and park areas, and the borough was divided into four groups, the average height of buildings and percentage of ground area to be built upon in each group being estimated. The future consumption per 1,000 sq. ft. of floor area was taken as 350 gallons for that section of the city below 59th Street, to provide a margin of safety in the estimates.

The experience of the past three years has shown that the floor area basis is useful also in the following work: (1) To determine what is the reasonable consumption in districts which are being surveyed by use of the pitometer, thus determining whether further investigations to detect leakage are advisable; (2) to determine consumption in individual blocks or groups of several blocks, where it is proposed to extend high service to cover districts previously supplied from low service; (3) to determine whether metered consumption indicated for large buildings is probably correct, where question has risen as to the presence of illegal connections; (4) to determine size of tap that should be granted for a new building.

The following illustrations of the use of the floor area basis in connection with gaugings of flow into districts and the use of water in buildings are of interest. In measuring the flow of water into one district in 1902-03, an error was made in the direction of flow through one of the large mains included in this district. The flow in this main, which was about 5,000,000 gallons daily, was taken as being into the district, whereas it should have been out of the district. The resultant error was, therefore, about 10,000,000 gallons daily, or about equal to the actual flow into the district. The resultant per capita consumption was 93 gallons, and was not considered to be abnormal. When the floor area unit was applied to this district it was found that the consumption per 1,000 sq. ft. was over 600 gallons per day, whereas no other district was found where the consumption had equaled 400 gallons, and few had exceeded 300 gallons. Investigation and subsequent measurements of flow in the district clearly showed the error, which was only discovered by applying the floor area unit.

The question of the presence of one or more illegal connections between the city's mains and the piping system of one of the large hotels was brought up. It was found that to measure the flow in the street mains and thus check the meters in the buildings would necessitate several taps, and the size of the mains was such that the rate of flow would be too small to give a reasonable degree of accuracy in the readings that might be obtained. To make the necessary taps and take readings would have cost several hundred dollars and would have interfered with traffic on two of the most congested streets in the city. A comparison of the use of water in this building on the floor area basis with that of several other buildings of like character showed that the building in question used more water than any of the other buildings. The evidence, therefore, was conclusive that the full amount of water supplied was passing through the meters.

The per capita basis for estimating consumption is the most practical one for general use, and will undoubtedly continue to be the standard unit. Experience with the floor area basis in New York city has shown, however, its usefulness in waterworks operation, and it is believed that other cities than New York will find occasions where the floor area basis can be utilized to advantage.

TESTS OF CAR HEATERS.

An investigation has been made by the Cleveland Railway into the merits of various systems of heating trail cars for rush-hour service. The investigation was carried on under the supervision of T. Scullin, master mechanic of the Cleveland Railway, and J. H. Alexander, chief engineer for the City Street Railroad Commissioner of Cleveland. It was witnessed by Street Railroad Commissioner Witt and by representatives of the various car heater manufacturing companies whose apparatus was concerned in the test. An abstract of the report made as the result of this investigation follows:

"Three types of heaters were tested, namely, straight electric heaters, the forced ventilation electric heater and the forced ventilation coal heater.

"The tests were made upon three of the railway company's 900-type cars, having an over-all length of 52 ft., the front vestibule being inclosed and the rear vestibule open. Each type of heater was installed in a separate car. The tests were made with the cars end to end on a track in the shops of the railway company. Two side ventilator sashes in the front of the car and two in the rear were open during the entire test. The straight electric heater system manufactured by the Consolidated Car Heating Company was installed on car No. 909 and consisted of twenty-six heaters, installed underneath car seats, one main switch cabinet, one magnetic switch, one thermostat and one snap switch. The forced ventilation electric heater manufactured by the Peter Smith Heater Company was installed on car No. 911. It consisted of a compact electric heating unit in a sheet steel housing, equipped with a Sturtevant multivane blower, size C, direct-connected to a 2.0-volt, 8-amp series-wound, ball-bearing motor. The cold air taken from underneath the car is blown over the heating coils and distributed from a hot-[illegible] the length of the car floor. This heater is [illegible] with an [illegible] and thermostat [illegible] the temperature of the car automatically. The forced ventilation coal heater [illegible] on car No. [illegible] was [illegible] by the Peter Smith Heater Company and [illegible] heater described above except that the heat is obtained by the direct combustion of coal, the cold air being blown over the combustion chamber.

"The tests were started [illegible] on [illegible] after the cars had been standing in [illegible] building for about twenty-four hours.

"The temperatures within the car were taken by [illegible] thermometers [illegible] and at the [illegible] below the ceiling, and one in the centre of the car at about the height of the seat back. The latter temperature was considered to be representative of the temperature of the air in the portion of the car occupied by the passengers. The temperature indicated by the thermometers just under the ceiling was practically the same as that indicated by the thermometer in the centre, on the car equipped with the Consolidated heaters, and about 1 deg. to 2 deg. higher on the car equipped with the forced ventilation electric heater, while on the car equipped with the coal heater one temperature was slightly higher and one slightly lower than that in the centre of the car.

"The outside temperature considered in the test was that taken at about the height of the car windows. The temperature of the intake air to the forced ventilation heaters was about 2 deg. to 4 deg. lower than the temperature at the height of the car windows, while the temperature of the air about 3 ft. above the roof of the car was 2 deg. to 3 deg. higher. A five-hour continuous heat run was made on the three cars, an employee of the railway company being stationed in each car to take thermometer readings at a signal from the recorder. The first few readings were taken at intervals of two or three minutes, in order to obtain the curve of temperature rise of the car.

"The run on the car equipped with the coal heater was not successful, owing to the insufficient draft of the heater while in operation in the building, and another test was made subsequently on this car. In this test a fan was placed on the car roof, blowing the air over the top of the smoke-jack, which gave the draft desired.

"On this latter test more thermometers were available and they were distributed over the sides of the car to determine what effect the heat radiating from the side of the car when the car was not in motion would have upon the envelope of air close to the car body. These temperatures indicated that with the car in actual service there would be a greater radiation from the windows and a slightly greater radiation from the roof of the car.

"The tests run on the two electric heaters show that in order to maintain a temperature within the car 41.9 deg. Fahr. above the surrounding air it is necessary to expend about 10,900 watts, of 267 watts for each degree rise of temperature

"The mean temperature of Cleveland for forty years for each of the winter months was obtained from the United States Weather Bureau, and the number of degrees of heating required to maintain a temperature of 55 deg. Fahr. inside the car was determined. It was also assumed that the current must be turned on the heaters a sufficient length of time to raise the temperature to 45 deg. Fahr. before the car goes into service, also that the car remains in service two hours in the morning and two hours in the evening."

In the comparison of costs of electric and coal heaters the contract under which the Cleveland Railway purchases energy was used for determining the cost of the electric heaters. The figures follow:—

Estimated Cost of Power for Electric Heater for Trail Cars on Basis of One Car per Year.

Maximum demand at car from test (500 volts)	11.00 kw
Maximum demand at d.c. bus substation (90% efficiency of distribution)	12.23 kw
Maximum demand at generator bus (80% efficiency of transmission and conversion)	15.30 kw

12.23 kw for 2½ hours requires 8.16 kw of substation capacity, 50% overload allowed.

Investment in substation, 8.16 × $25 = $204.00 ($25 per kw of capacity installed.)

Fixed charges on substation equipment, $204 × 10% = $20.40.

(Includes 5% interest, 2.52% amortization, 1.36% taxes =9.88% or 10% used.)

Investment in distributing system is $41.70 per kw of maximum demand.	
Investment in distributing system per car, $41.70 × 12.23	$510.00
Fixed charges per car per year, $510 × 10%	51.00
Maintenance of distributing system per kw of maximum demand per year	2.00
Maintenance of distributing system per car	24.46
Consolidated car heaters require 4661 kw-hr. at car or at generator bus, 4661 ÷ .80 = 5830 at $0.0038	22.15
Substation operation and maintenance, 5190 × $0.0003	1.56
Peter Smith forced draft heater required 4172 kw-hr. at car, or 4172 ÷ .80 = 5220 kw-hr. at generator bus, 5220 × $0.0038	19.80
Substation operations and maintenance, 4640 × $0.0003	1.39

Summary of Power Cost.	Consolidated Electric Heater.	Peter Smith Electric Heater.
Demand charge for power, 13.76 kw for 6 months	$82.50	$82.50
Energy charge	22.15	19.80
Substation operation and maintenance	1.56	1.39
Fixed charge on substation	20.40	20.40
Fixed charge on distributing system	51.00	51.00
Maintenance of distributing system	24.46	24.46
	$202.07	$199.55

Peter Smith Coal Heater:	
Fixed charge, .182 kw at $16.22	$2.95
Substation operation and maintenance, 148-kw-hr. at $0.0003	.04
Energy charge, 166 kw-hr. at $0.0038	.63
Total	$3.62

In building the fire in the coal heater, the following material was used: Kindling, 1.76 lb.; ash wood, 4.25 lb.; kerosene oil, 0.312 lb.; shavings, 0.004 lb.; coal, 35.29 lb.

In the general summary, each heater was charged with interest at 5 per cent. taxes at 1.36 per cent. and repairs and maintenance at 1 cent a day. Depreciation was charged at 7 per cent. in the case of electric heaters and 10 per cent. in the case of coal heater. The latter was also charged with the following special costs per year:

Coal	$21.00
Fuel and labor of kindling fire thirty times	4.09
Labor of attendance	8.76
Removing and reinstalling heater each season	1.00
Transportation and storage in summer	.50
Value of space occupied by heater	11.16

The final figures showed that the Peter Smith coal heater to be far more economical than either electric heater.

In regard to weight and space occupied and a general summary the report says:

"The weights of the various heaters installed complete are as follows: Consolidated, 457 lb. Peter Smith electric, 350 lb.; Peter Smith coal heater, 544 lb.

"The cost of power for hauling the equipment for this trailer service amounts to 2.18 cents per pound per year. The Consolidated electric heating equipment is carried throughout the year, while with the Peter Smith forced ventilation heating equipments the heating duct alone is carried throughout the year, the heater being removed and stored during the summer season.

"Either of the electric heaters installed in a car would be placed under the seats, while the coal heater during six months of the year occupies the space of one seat in the car; the value of this space is chargeable against this heater. In order to obtain this value it was assumed that the standing capacity of the car is one-half as valuable as the seating capacity. Thus in this car, seating sixty passengers and providing standing room for sixty more, the value of one seat space is one-ninetieth of the value of the car space. On a basis of 38 miles per day for a trailer 156 days per year, the mileage per heating season is 5920, which at 17 cents per car mile operating cost amounts to $1,006.40. Therefore $11.16 is the value of the space occupied by the coal heater during the winter season.

"Each of the three types of heaters has its individual advantages. The electric heaters afford the advantage of cleanliness, convenience and ready means of obtaining automatic regulation of the car temperature. The Peter Smith electric heater has the important additional advantage of providing a forced ventilation of about 12,000 cu. ft. of fresh warm air per hour. On the Peter Smith electric heater, however, no means were provided for automatically cutting off the current of the heating unit in case of failure of the blower motor, which would probably mean a burn-out of the heating unit. Both of the electric heaters have the disadvantage of being unable to heat the car properly in extreme weather. The curves show that in zero weather it would be impossible to maintain a temperature of more than 40 deg. Fahr. inside the car. With the coal heater a rise of over 48 deg. was obtained easily without any attempt at crowding the heater. The exceptionally high cost of power for heating the tripper cars electrically at rush-hour periods of the day for the climatic conditions existing in Cleveland renders the operation of electrical heaters extremely uneconomical if not prohibitive."

METHODS OF REINFORCING A BRIDGE.

Reinforcing a bridge in such a way as to make the added material share not only in the live-load but also in the dead-load stresses was done on the Bengal-Nagpur Railway, India, according to the methods described by D. H. Remfry in a recent paper before the Institution of Civil Engineers. The bridge consisted of ten 200-ft. deck-truss spans, and two 100-ft. spans. Each span, during the reinforcing, was jacked up at six points, to take out most of the dead-load stress. The jacks were supported by falsework founded on 42-in. steel cylinders sunk in the sandy river bottom (and after using pulled and used again).

Special rivets were tried in the reinforcing, because some of the gussets furnished little room for driving additional rivets. The special rivets, of chrome-vanadium steel, had 45 per cent. greater shearing strength than mild steel, and, curiously enough, "tests seemed to indicate also that a greater bearing resistance could be relied upon in the plates when these special rivets were used, than with mild-steel rivets."

The success of the reinforcing is described in the statement: "Practically no permanent set was observable on the first passage of a train after strengthening." The deflections of the spans under live-load were 26 per cent. to 30 per cent. less than before reinforcing.

WAVES IN LONG HYDRAULIC PIPES AND TUNNELS.

The subject of surges in pipe lines is an exceedingly interesting one to the hydraulic engineer. The following contribution by Robert H. Smith appeared in a recent issue of "The Engineer," London, and will be of interest to our readers, so that we have published it in full.

During last summer the Institution of Mechanical Engineers visited the great hydro-electric works of North Switzerland. The most interesting of these is that on the Löntsch River, the supply being from the Klönthalersee, a natural lake whose storage capacity has been increased to 50 million cubic metres by the building of a dam 21 m. high. From the lake the water flows through a tunnel cut in the rock of the face of the mountain side, a distance of 4.1 kiloms., with a cross section of 4¾ square metres and a gradient of 2.17 per 1000. At the end of the tunnel there is a sort of water tower, from which the water flows through three welded steel pipes 1¼ kilom. long and of diameter varying from 1.35 to 1.2 metre, down to the power-house at 325 m. lower level.

The variation of the water taken by the turbines causes corresponding change in the flow through the tunnel. Although the linear velocity of the water is never high, the immense weight of water flowing means a huge and quite irresistible momentum, so that not only must the valves be closed and opened with great care, but it is necessary also to provide what is in effect a gigantic relief valve at the lower end of the tunnel. The above-mentioned sort of water tower serves this purpose. Rising from the end of the tunnel is a sloping shaft cut through the rock and with a small connection for its overflow to the free air at [illegible] higher level than the tunnel end. At [illegible] m. above this tunnel end is cut horizontally a long gallery which acts as a small subsidiary reservoir, into and out of which a large quantity of water can flow quickly. A second similar but larger gallery at 30 m. level above the tunnel end acts in the same way. During the deceleration of momentum in the tunnel when valves are closed, water flows up the sloping shaft and into the upper gallery, and during acceleration after the opening of the valves the extra supply to the turbines is for a time partially obtained by outflow from the lower gallery. The difference of water level between the Klönthalersee and the water in the sloping shaft is the head or driving force, which (1) overcomes frictional resistance to flow through the 4.1 kiloms. long tunnel, which resistance varies with the velocity, and (2) produces plus or minus acceleration of momentum in the water mass filling the tunnel. This head changes quickly during closing or opening of the valves owing to the filling or emptying of the galleries and sloping shaft. The result is the setting up of oscillations or waves, which continue for some time after the disturbing operation of the valves has been finished, but which are gradually damped down by the frictional resistances.

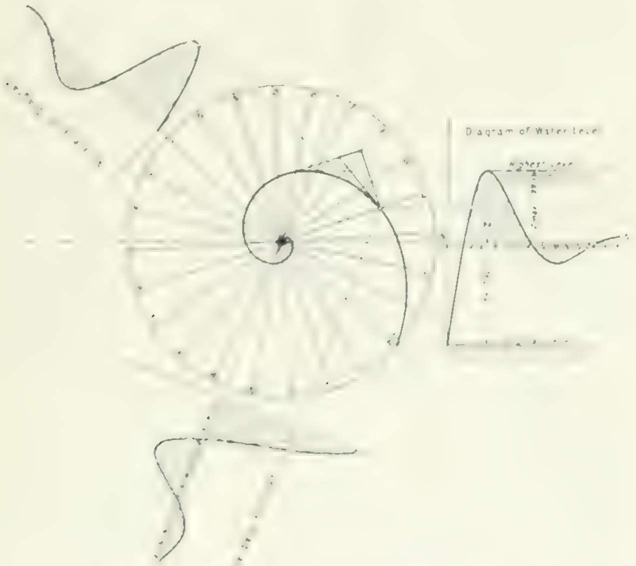

Fig. 1.—Diagram Illustrating Case 1.

Normally the lower of the two relief galleries is full, the water is level in the sloping shaft being above it. On the opening of a valve the level in the shaft sinks rapidly and the driving head increases rapidly until the level of the lower gallery is reached, when it remains practically constant for some time until this gallery is emptied—if the change in the supply goes so far as wholly to empty it. On the other hand, when valves are closed, the level being normal above the lower gallery, the level in the sloping shaft rises quickly and a quick decrease of driving head occurs until the water reaches the level of the upper gallery, when it practically remains constant, the overflow lip of the waste weir placing a limit upon this decrease of head.

All hydraulic engineers are familiar with the dangerous effects due to the acceleration and deceleration of large masses of water in long pipes. For great works like those of the Löntsch Valley it is, therefore, of great importance to arrive at a knowledge as accurate as circumstances will permit, of what occurs under conditions such as those described. Dr. Franz Prásil is the best known Swiss expert in hydraulic calculations. His excellent paper on "The Efficiency and Governing of Modern Turbines," read at the summer meeting of the Institution of Mechanical Engineers at Zürich, will be in the recollection of our readers. In Nos. 21, 23, 24 and 25 of the fifty-second volume of the Schweizer Bauzeitung, he has given a full and learned investigation of this "Water Tower Problem" of the waves or swinging motion of water in long pipes and tunnels.

It would be impossible in a single article to follow the mathematical course of Dr. Prásil's calculations, and only a small number of your readers would care to examine them so far as to judge for themselves of their correctness. It will be interesting, however, to give a brief account of their general results and of the degree of approximation to physical fact to which they pretend. Dr. Prásil starts his paper from the beginning of all things, and his first pages are devoted to arriving at the general equation for damped vibrations. We can leave this first part without further mention, because this equation is well known to electrical engineers in its relation to damped electrical oscillations. Applying it to the problem of water waves in pipes damped down by friction, and changing the letters used by Dr. Prásil to those in more familiar use by British engineers, this equation may be reduced to the following, which is its simplest general form:—

With Nomenclature.

Length of tunnel = l
Cross-section of tunnel = a
Horizontal cross-section, or water surface in water tower = A
Height of water level in water tower above water level in supply reservoir = h
Volumetric discharge of water through valves beyond water tower = q
Frictional and viscous coefficient of resistance to flow through tunnel = f
Time reckoned from beginning of disturbance due to closing or opening of valves = t
Acceleration of gravity = g

For any steady positive flow through the tunnel the head h is negative; but the wave may, and does, carry water up into the tower so as to make h positive in spite of q, the flow through the discharge valves, remaining positive, and while also the flow forwards through the tunnel remains positive. While h is positive, however, and also while it is negative up to a certain limit, deceleration takes place in the tunnel flow. During the steady flow before the disturbance commences the value of h is called h_n and the discharge flow q_n the suffix n indicating the word "normal."

The frictional resistance to the flow through the tunnel is assumed to be approximately proportional to the first power of the linear velocity, and the total head lost in the whole length of the tunnel in overcoming this resistance is taken $= f \times$ velocity. Of course, f depends upon the dimensions and the smoothness of the surface of the tunnel. For high velocities the actual resistance is more nearly proportional to the square of the velocity; but the above assumption greatly simplifies the calculation and makes only little difference in the practical result of it, while the difference is on the safe side, inasmuch as the true physical law damps down the oscillation more vigorously and more quickly than does this approximation.

It must also be mentioned that the problem is worked out on the assumption that the water surface area A remains the same at different levels in the water tower.

The fundamental general equation is:—

$$l A \frac{d^2 h}{d t^2} + g f A \frac{d h}{d t} + g a h + g f q + l \frac{d q}{d t} = 0$$

The sum of the first and last terms of this equation represent the acceleration of momentum of the mass of water in the tunnel. The sum of the second and fourth terms represents the frictional resistance. The middle term represents the driving head. Or, more definitely, these terms divided by $g a$ represent the quantities just mentioned. The first three terms are placed here consecutively in mathematical order for the variable head h; the last two in order for the variable q. These two, h and q, are the only two quantities involved which vary; and they vary independently of each other.

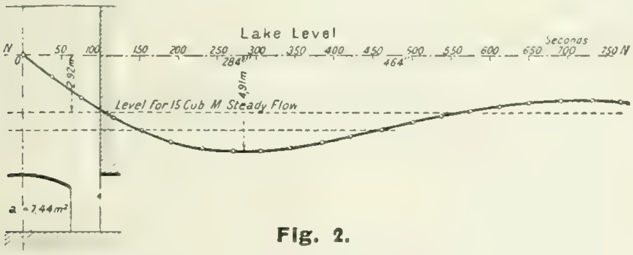

Fig. 2.

Except when the valves are wholly closed, or $q = 0$, it is not possible practically to keep q quite constant; but the first two special cases are worked out on the assumption that q does remain constant, when also the last term $l \frac{d q}{d t} = 0$. This greatly simplifies the solution and gives a very good preliminary notion of the sort of results to be expected in all cases of more complex conditions.

Before stating the results for special cases there must here be noticed what appears to the present writer to be the most serious deviation from actual physical fact embodied in Dr. Prásil's solution. This is the assumption that the whole mass of water in the whole length of the tunnel moves at each instant of time with exactly the same velocity. In a short length of pipe like that between the buckets of a reciprocating pump and its delivery air vessel, this is a very close approximation to physical fact. But in a large tunnel a couple of miles long the error is very much greater. It is so because of the air dissolved in the water. If the water contained no air it could be treated mathematically as a practically inelastic and incompressible mass; the changes of pressure would be transmitted practically instantaneously through the total length, and every part would suffer the same acceleration or deceleration at each instant of time. But under the actual changes of pressure the contained air contracts and dilates; and, in consequence of this, the changes of pressure are transmitted along the length as waves at a velocity very far from approaching "infinity" in comparison with the time period of a complete oscillation of the water velocity; and the result is that the successive periodic water velocities do not arise all along the tunnel at the same instant, but the appearance of each is retarded by an appreciable time at each place in proportion to its distance from the end where the disturbing influence has its origin. Moreover, in a long tunnel there are unavoidably many roof pockets where air gathers, and the quantity of air in each such pocket increases whenever the pressure increases, as every one knows how air is thrust out of ordinary undistilled water on any considerable pressure being applied to it. These air pockets constitute so many highly elastic cushions which must modify in no negligible degree the mathematical results based upon complete incompressibility.

Another approximation made by Dr. Prásil is to neglect the accelerations of momentum of the water in the water tower itself. It is probable that in all actual cases this is a perfectly permissible approximation having no appreciable effect upon the practical result.

Special Case I.—Dr. Prásil first solves the problem for the case of quite sudden partial closure of the discharge valves. Before the closure the water level in the water tower is h_n and the discharge flow q_n. The discharge is suddenly reduced to q, and remains at this amount during the following waves and until steady flow has been again established by frictional damping.

If 2π T (= 6.28 T) be the total period of the resulting wave—that is, the time interval between successive maximum water levels in the water tower—Dr. Prázil finds that this time is given by the equation

$$T = 2 l \sqrt{\frac{A}{g (4 a l - g f^2 A)}} .$$

It is to be noted that this time increases with the length of tunnel; that it increases with the ratio A/a of the section of the water tower to that of the tunnel; and that it is also increased by greater frictional roughness of the tunnel walls. It is to be particularly noticed that it is independent both of the previous and final flows q_n and q and also of h_n, the head previous to the closure.

After the waves produced by the sudden change of discharge have been completely damped out by the frictional resistance, the steady permanent new head of water from reservoir level to level in water tower is diminished

$$\text{from } - h_n \text{ to } - \frac{q}{q_n} . h_n .$$

The progress of the wave as expressed by the rise and fall of water level in the water tower is given by the equation

$$h = - \frac{q}{q_n} h_n + \left(1 - \frac{q}{q_n} \right) h_n \frac{a}{f A} T \frac{\sin\left(\frac{t}{T} - \beta\right)}{e^{\frac{f}{2 l} t}}$$

The second term here measures the wave motion and shows that this oscillates round the level $- \frac{q}{q_n} h_n$ to which the water in the tower quiets down. The amplitude of this wave motion is proportional to $\left(1 - \frac{q}{q_n} \right) h_n$ the difference between the original and the final head. It is also proportional to T; but as T involves f a and A it is better to consider the whole factor $\frac{a}{fA}$ T, which equals

$$\frac{2al}{f\sqrt{gA(4al - gfA)}}$$

This increases with $\frac{a}{A}$ the ratio of tunnel to tower section, increases with l the length of tunnel, and decreases as f the frictional roughness of the tunnel increases. There is a purely theoretical limit to this last decrease at dimension ratios which never occur in problems when it is useful to make these calculations. At the same limit the increase of the wave time-period with the length of tunnel would change to a decrease.

The amplitude of the wave is continuously damped down with the advance of the time t from its initiation. This gradual diminutions is measured by the division by the factor $e\,\frac{g}{2l}t$ where e is the base of natural logarithms. Dr. Prásil expresses this graphically in a diagram as the polar ordinate to a logarithmic spiral. The rate of increase of the radius of the spiral is proportional to the roughness f and inversely so to the tunnel length l.

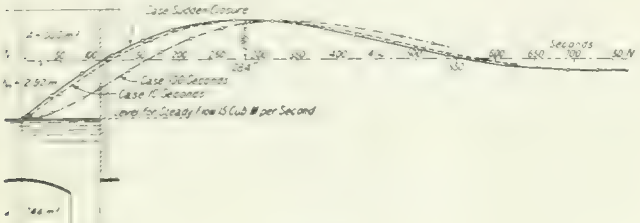

Fig. 3.

The angle β in sin $\left(\frac{t}{T} - \beta\right)$ expresses the phase of the wave motion at which it starts under the somewhat artificial assumption of instantaneous change of discharge from q_n to q. The physical meaning of β is that at time βT the water in the tower reaches, and passes above, the level to which it finally settles when the wave is completely damped out.

To calculate β the equation is

$$\sin\beta = \frac{4lgfA}{[illegible]} = \frac{f}{2al}\sqrt{gA(4al - gf^2A)},$$

and this calculation is necessary in order to find the maximum height to which the water will rise in the tower.

The maximum water level is reached at the time given by

$$[illegible]$$

[illegible]

[illegible] square metres;

[illegible]

Results:—Whole period of wave = 2π × 147 sec. = 15 min. 9 secs.

β = 41 deg. 24 min.

Time of first maximum height of wave = 6 min. 24 secs.

Height of first maximum above lake level = 1.99 m.

Depth of first minimum below lake level = 0.61 m.

Final level in water tower = level in lake.

In Fig. 1 are seen the various diagrams used to assist in and illustrate the solution of this special example.

In this example the original kinetic energy of the mass of water filling the tunnel is 4271 metre-tons. The weight of water lifted into the water tower during the rise of level to the first maximum is 2455 tons. In coming to the final level this weight does work equal to 2455 × 29.2 = 7169 metre-tons. The sum of these two quantities of energy is spent partly in lifting 2455 tons through the height 2.455 m. or 6027 metre-tons, and partly in overcoming frictional resistance to the amount of 5413 metre-tons.

Special Case II.—The second special case worked out by Dr. Prásil is that of sudden opening of the discharge valves after being wholly closed. In this case q_n = O and h_n = O. It is obvious that in consequence of inertia the flow through the tunnel will start into being gradually, and also that the discharge through the valves will increase gradually from zero. But as a first approximation Dr. Prásil works out the mathematical ploblem on the assumption that the valve discharge increases instantaneously to q and remains constant at this amount until the disturbance wave has been damped out.

The result is shown in Fig. 2. It is the precise reverse of that in special case I., it being made so by taking the final steady flow q equal to the flow corresponding to the 2.92 permanent head of water, namely, 15 cubic metres per second.

The level in the water tower sinks to the minimum level under that of the reservoirs of 4.91 m. = 2.92 + 1.99. It Galley Four—Waves In Long Hydraulic Popes And Towers subsequently rises to 2.92 — 0.61 = 2.31 m. below the same level. The following oscillations are of successively smaller range. The total time period of the wave is again 15 min. 9 sec. The angle β is again 41 deg. 24 min., corresponding to a falling passage through the final level at the time 1 min. 44 sec., the subsequent rise through the same level occurring at time 9 min. 19 sec.

Special Case III.—The third case taken is that of gradual closing of the valves so as to decrease the discharge at a uniform time rate from q_n to O in time t_c. Here

$$q = q_n\left(1 - \frac{t}{t_c}\right) \text{and} \frac{dq}{dt} = -\frac{q_n}{t_c}$$

The solution for the water level in the tower is in this case

$$\frac{h}{h_t} = \frac{1}{f}\sqrt{\frac{al}{Ag}}\,\frac{(\sin\frac{t}{T} - \beta)}{e^{[illegible]}} + t \quad [illegible]\; al - gf^2A$$

This is evidently an exactly similar solution to that given in Cases 1 and 2, except for the addition of a straight line term, namely t. Adapting the appropriate constants the same graphic construction applies, substituting an oblique straight line as the base from which to measure. Thus, if the distances along the horizontal axis in the diagram be the time t and the vertical ordinates be to a curve drawn in the same manner as in Cases 1 and 2, then the height between the curve and a straight line drawn through the origin downwards at 45 deg. will give the values of $\frac{h}{h_n}t_c$. The values of T and of β are here the same as those already given.

After the valves have completely closed the wave continues, but under changed conditions, the change being expressed mathematically by the omission from the equation of the above-mentioned straight line part, with also a change in the values of β and of the factor of the sine term. These new values depend upon the point in the above diagram, which makes the time $t = t_e$ The value of h for this point can be found algebraically from the above equation by inserting in it the value $t - t_e$.

Fig. 4 gives Dr. Prásil's diagram for the solution with the same data as taken in the illustrations of Cases 1 and 2 and for the uniform complete closure of the discharge occupying 200 sec.

He calculates the results also for complete closure in 10 sec. and in 100 sec. These three results along with Case 1 for instantaneous closure or closure in O second, form a series which well illustrate the effect of more or less rapid stoppage of the flow through the discharge valves. The more important of the practical results are brought together in the following table:—

Table of Results of Stoppage of Discharge in 0, 10, 100 and 200 Seconds.

Full flow 15 cubic metres per second.

Length of tunnel, 2.76 kilom. Section of ditto, 7.44 sq. metres.

Head from lake to water tower for full flow, 2.92 m.

Time period if wave, 15 min. 9 sec.

Full closure of valves, in sec.	0	10	100	200
Head at instant of full closure, m.	2.92	2.77	1.48	0.32
Head at lowest dip of wave, m.	0.61	0.60	0.53	0.44
Negative head at top of wave, m.	1.99	1.99	1.95	1.82
Factor of sin $\left(\frac{t}{T} - \beta\right)$ in formula for h at top of wave, m.	4.417	4.358	3.825	3.188
β deg min.	41 24	39 30	22 44	5 46

The level of the water at the top of the wave being the most important quantity, it is seen that this varies very little; it begins to decrease perceptibly only with periods of closure longer than 1½ min. In Fig. 4 the three curves for 0, 10, 100 sec. are plotted together and to the scale of the diagram the differences between them are barely measurable. Dr. Prásil therefore concludes that for practical purposes the much simpler calculation based upon the assumption of instantaneous closure, either complete or partial, is sufficiently accurate, especially as it deviates from exact physical truth in the direction of safety in the provision to be made in designing the water tower.

Dr. Prásil then proceeds to investigate the results of sudden opening almost immediately followed by sudden closure, a condition arising in the supply of electric energy to tramways of limited extent and not very frequent service so that the load curve is very peaked, and also the effects of an overflow or waste weir at the top of the water tower such as we see in the Löntsch Valley. The necessary limits of this article prevent us following him further in these analyses. He also gives a careful examination of the difference resulting from using the formula $f v^2$ instead of $f v$ for frictional resistance to water flow.

His general conclusions are as follows:—

1. If in place of a water tower the relief opening is into a reservoir of water area A, and if A/*a* be greater than about 100 *l* in kilometres then no periodic wave motion will occur on opening and closing the discharge valves, the frictional damping effect preventing this; but in ordinary practice where A/*a* is much less than this such waves will arise.

2. The maximum height of the wave is reduced very little by gradual closing of the valves below what is calculated for sudden closing.

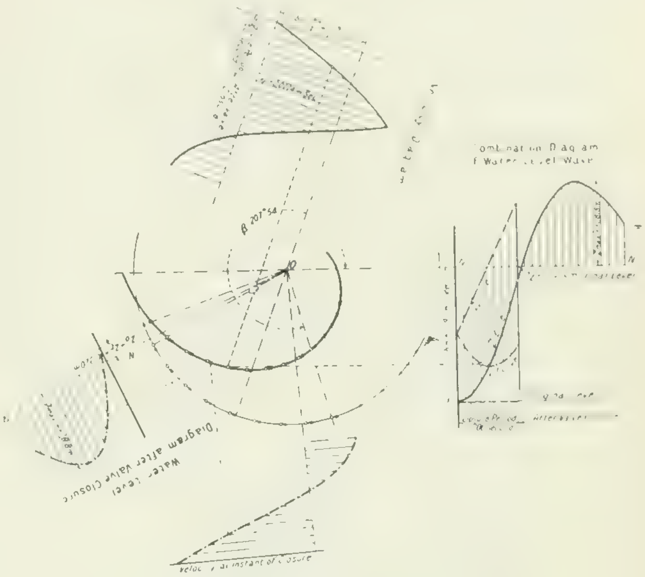

Fig. 4.—Diagram Illustrating Case III.

3. The approximate height of the wave can be calculated by help of a work balance account.

4. The maximum dip of the wave due to opening is nearly the same as the height calculated for closing the valves.

5. The theory of damped vibrations gives approximately correct results when applied to this problem.

6. In a service in which periodic variations of discharge take place the phenomenon of resonance may arise under certain conditions.

7. The maximum height of wave may be limited by the use of an overflow weir arranged at top level of the water tower.

GAS RATES IN MONTREAL.

The town of Montreal West, being the extreme western end of Westmount, which in turn is the west end of Montreal, has adopted a twenty-year contract with the Montreal Light, Heat and Power Co., for the supply of gas for lighting and heating and industrial purposes. The terms are $25 per light per annum for lighting the roads, streets, lanes and other public places, the posts to be supplied by the town and the lamps and apparatus by the company.

The rates for private lighting will be as follows per 1,000 cubic feet:

For the first five years, $1.25.
For the second five years, $1.15.
For the third five years, $1.05.
For the fourth five years, $1.00.

These quotations are net; and the company also reserves the right to charge an extra 10 cents per 1,000 cubic feet to persons who do not promptly pay their accounts. It is also provided that if the town of Montreal West is hereafter annexed to the city of Montreal, the terms given to the customers in the city shall be extended to the citizens of Montreal West, after the second term mentioned above.

It may be of interest to add that recently the company made a rate of 95 cents per 1,000 cubic feet to the citizens of the city of Montreal.

ELECTROLYSIS FROM STRAY ELECTRIC CURRENTS.*

By Albert F. Ganz, M.E.†

Electrolysis is defined as chemical decomposition by means of electric currents. Stray electric currents escaping from grounded electrical distribution systems which reach underground pipes cause destruction from electrolysis where these currents leave the pipes for the surrounding soil, because soil is an electrolytic conductor. Theory and experience show that the weight of metal destroyed by electrolysis is independent of the voltage, except in so far as this determines the amount of current produced, and that this corrosion is directly proportional to the amount of current leaving the pipe and to the time during which it leaves.

In practice the only serious sources of stray currents are single trolley direct-current electric railways. In these railways the running tracks are used as the return conductor, and for this reason they are connected to the negative bus-bar of the power station by return feeder cables. In most systems the tracks are connected to the negative bus-bar directly at the power station, and there are many systems where there are no further return feeders. The running tracks of such single trolley railways are usually in contact with ground, and since there is a drop in voltage in the rails, current leaks from the rails to flow through ground, the amount of stray current depending upon the drop in voltage in the rails and upon the resistance of the path through ground. Since electric current can only flow in a closed circuit, all current which leaks from rails and flows to ground and on underground pipes must again leave these pipes where negative return feeder cables are connected to the rails, in order to flow back to the negative terminal of the generator and so complete the electric circuit. Where these stray currents leave these underground pipes to flow to the surrounding soil electrolytic corrosion is produced, resulting in a destruction of 20 lb. of iron in one year for every ampere of current. It has been disputed whether the amount of destruction produced is always equal to the theoretical amount; a number of laboratory experiments made recently by the author under practical conditions with current densities as low as those found in practice on underground piping seem to indicate that the actual amount of destruction is always at least equal to the theoretical amount, and is often even greater than the theoretical amount.

Since stray currents flowing through ground and through underground piping are caused by potential differences between the pipes and rails set up by the drop in voltage in the rails, the simplest way to determine the probable existence of stray current on underground piping it to measure the potential differences between pipes and rails. Such measurements made throughout a system constitute the usual potential survey. These potential differences are, however, not a measure of the current flow between pipes and rails, as this is determined also by the resistance of the path through the intervening ground, and this resistance cannot be practically measured. Since the actual electrolytic danger of a pipe is determined by the amount of current flowing on the pipe, it is necessary to make current measurements at several points throughout a piping system. The amount and direction of current flow on a pipe can be determined from drop measurements between service connections, but the magnitude of the current flowing cannot be determined from such drop measurements. To determine the actual amount of current flowing a length of pipe is exposed and the drop in potential along a known length of continuous pipe is measured, and this drop is divided by an assumed resistance for the included length of pipe.

Since the positive potential of a pipe referred to rails, plus the negative potential of the pipe referred to rails, plus the drop in the pipe, is equal to the drop in the rails, the potential and current surveys enable one also to form an estimate of the drop in rails, and thus to form an idea as to the condition of the railway return circuit.

After drop and current measurements have been made at a sufficient number of points, they are conveniently plotted on a mains map, and a study of this map will indicate where current is leaving the pipes. Such points will always be found in the regions where the pipes are positive to the rails. Other points remote from the positive region will in most cases also be found where current leaves the pipes to flow to other pipes or to other underground metallic structures, or to flow to ground in cases where the negative bus-bar is grounded through low resistance ground connections. The author has found large stray currents leaving water pipes in districts where these pipes were from ten to twenty-five volts negative in potential to the trolley rails, and more than five miles away from the railway power station. At points where the current survey indicates current leaving excavations should be made and the pipe examined for evidences of electrolytic corrosion.

Besides the danger from electrolytic destruction of the pipes, stray currents where they flow on underground piping systems frequently enter buildings through service connections and produce a serious fire hazard. For example, current may flow into a building through a water service pipe, then flow from the house water piping to the house gas piping, and then out from the building through the gas service pipe. Such contacts between service pipes or between the service pipe and the lead sheathing of a telephone or a power cable frequently occur through metal ceilings, or where the pipes rest against each other. Since dangerous heating may be produced where the current flows through such contacts or where vibration may momentarily separate the contact and produce an arc, nearby inflammable material is in danger of being set on fire. The author has, in fact, found many cases where currents up to 30 amperes were flowing into and out of buildings through service pipes or lead cable sheaths. Evidences of arcing having occurred between such contacts in buildings have also been found. There is no doubt that many fires have started in this way, but it is always difficult to prove the cause of a fire because of the destruction resulting from the fire.

There is only one complete remedy for electrolysis, and that is the use of a completely insulated return circuit. Such railways may be provided with double overhead trolley wires, as used in Washington, D.C., Cincinnati and Havanna; or with an insulated outgoing and return current in underground conduits, as used on the surface lines on Manhattan Island; or with separate insulated third and fourth rails for the outgoing and return current, as is used on the Metropolitan District Railway in London. With these systems the running tracks are not used as a part of the electric circuit, and as both positive and negative sides of the circuit are insulated no stray currents are produced.

Where a road operates on a private right-of-way, the rails can often be practically insulated from ground and the escape of current from the tracks prevented. For surface roads this can sometimes be practically accomplished by placing the rails on wooden ties above ground and using broken stone for ballast and keeping the rails out of contact with ground. In the case of railway lines operating on elevated structures the rails can be fastened to wooden ties and kept out of contact with the structure. In one large elevated railway system this is done, and the running tracks, supplemented by large bare copper cables fastened to the wooden ties, are used for the return circuit. In this way the return circuit is quite thoroughly insulated from the elevated structure and from ground, thus preventing stray currents from this system.

---

* Abstract of paper read before American Waterworks Association at thirty-second annual convention, Louisville, Ky., June [illegible]

† Professor of Electrical Engineering, Stevens Institute of Technology.

A number of remedial measures intended to reduce stray currents from electric railways using the grounded rails for a return conductor have been tried. These methods may be divided into two classes, the first class aiming to remove the current harmlessly from pipes by metallic connections or bonds between the pipes and the railway return circuit, and the second aiming to minimize stray current through ground.

Since stray currents cause damage only where they leave pipes to flow to the surrounding soil, attempts are frequently made to prevent destruction from electrolysis by connecting or bonding the pipes or other structures by means of metallic conductors to the rails or to the negative return circuit, so as to remove the electric current by metallic conduction and thus prevent corrosion from electrolysis. This method can protect lead cable sheaths because they form continuous electrical conductors, but is not generally applicable to underground piping systems, because the latter do not form continuous electrical conductors, but are more or less discontinuous networks. While lead calked joints usually have a relatively low resistance, it frequently happens that they develop such high resistances as to make them practically insulating joints, due undoubtedly to the formation of oxide coatings. Cement joints and cement pipes have such a high resistance compared with iron pipes that they are practically insulating. Bonding of pipes to rails or to the negative return circuit can only afford local protection to the extent that the piping conducted forms a continuous metallic conductor, and this latter is an unknown and uncertain quantity in a piping network.

In the practical working out of a bonding or drainage system two opposing tendencies develop: first, there is a reduction in the difference of potential between pipes and rails in the positive areas, and consequent reduction of damage in those areas; and second, there is an increase of current flow on the pipes throughout the entire system, thus increasing the danger of trouble at high resistance joints or other places where two piping systems, or separate portions of the same system, are electrically discontinuous. As a rule, in the early stages of this system and especially in small networks when there are comparatively few bond connections and the resistances of the paths over the pipes are therefore relatively high, the effect is apt to be beneficial, reducing the danger in positive areas more than it increases the danger elsewhere. As the system grows and the load increases, more and heavier bonds become necessaary. The current on the pipes may finally become so great that the trouble from current shunting around joints or between separate systems will increase more rapidly than the danger in the positive areas is reduced, and any further increase in the bonding becomes an actual source of danger to the system. Since bonding transfers the trouble from the region where it was most evident to a new locality where it may require several years to manifest itself, the false impression is created that the trouble has been removed. It is due largely to this obscure and slow manner in which trouble develops that has caused this method to become quite widely used.

A number of cases have been reported where a main bonded to the negative return circuit at the power station was completely destroyed by electrolysis a block or two away because of a high resistance joint in the main, forcing current to shunt around the joint and leave the main a short distance away from the power station. In one of these cases one entire block of main had to be replaced. In another case the water main on one side of the street was bonded to the negative return circuit at the power station, and a main on the opposite side of the same street, although connected through cross-piping to the bonded main, was completely destroyed because high resistance joints had developed in the connecting pipes.

In addition, bonding pipes as a means of protection always renders the bonded structures a part of the negative return circuit, and therefore a source of danger to other underground structures which are not bonded. It has, in fact, been frequently found that where gas or water service pipes cross bonded cable sheaths, currents are induced to flow from the service pipes to the cable sheaths, and produce gradual destruction of the service pipes. In the case of one city 19 service pipes were destroyed in the course of one year directly where these pipes cross telephone ducts containing cables whose sheaths are bonded to the railway return circuit. One engineer who has studied this problem very carefully and entirely impartially has very aptly likened bonding to the drug habit, producing temporary relief at the expense of permanent and perhaps irreparable injury to the victim, which injury is, however, too rarely attributed to the true cause.

Experience shows that where there is serious trouble from electrolysis caused by large stray currents leaking from street railways, the bulk of this trouble is due to defective rail bonding, to ground connections from the negative bus-bar, and to lack of return feeders to bring current back from the rails to the power station. While stray currents can only be entirely eliminated by insulating the return circuit by the use of a double trolley, either overhead or in conduit, it is nevertheless a fact which is not generally appreciated, that where large stray currents exist, these can always be reduced to a small fraction of their present value by removing all ground connections of the negative bus-bar and installing insulated return feeders proportioned for equal drop from radially-disposed points in the track system located at some distance from the power station. By this method the rails are drained of current and any desired part of the voltage drop can be removed from the rails and transferred to insulated conductors from which currents cannot leak. In Europe such radial insulated return feeders for bringing current back from the rails to the power station are made necessary by regulations limiting the allowable drop in voltage in the rails, and in most cases such installations of insulated return feeders have substantially removed serious trouble from electrolysis.

This system of minimizing stray currents by means of radially-disposed insulated return feeders has also been installed in a number of American cities, and the method is gradually being recognized as by far the best for minimizing stray currents. This system, in fact, removes the root of the trouble by draining the rails of current and removing voltage drop from the rails and thus preventing substantial leakage of current through ground, and is therefore correct in principle. The railroad companies frequently object to this system, claiming that it is prohibitively expensive. This is certainly not the case, as is evidenced by the fact that the method is in general use in Europe and in a number of American cities to-day. The fact is that in many electric railways there is practically no installation of negative feeders and the railway companies are often not willing to install even a moderate amount of return feeder copper.

A mistake is often made in confusing the radial insulated return feeder system with paralleling the rails with copper. Of course, where the negative bus-bar is connected to the rails at the power station, and these rails are paralleled with copper feeders, the drop in the rails is reduced in the proportion that the conductivity of the return circuit is increased, but no part of the drop is actually removed from the grounded rails. The amount of copper paralleling the rails that would be required to reduce stray currents to a negligible amount would in all large systems be absolutely prohibitive. This, however, is not the case with the radial insulated return feeder system. With the latter system any desired reduction in rail drop and consequently in the amount of stray current can be secured, independent of the amount of copper installed, the amount of copper being determined by the allowable drop or power loss in the return circuit. The railway company can divide the annual charge of interest on copper invested and operating expense in any ratio within wide limits without affecting the amount of stray current produced from the system.

The pipe-owning companies suffer constant expense on account of stray railway currents in the form of repairs and depreciation of their underground structures, and in the form of liability for accidents, and this can be reduced with certainty to any desired extent, short of complete elimination, by the assumption on the part of the railway company of expense in the form of interest and power charges for its return circuit. The railway companies should in all fairness assume this expense and responsibility. If the railway companies would apply as much engineering knowledge and money to their negative circuits as they do to their positive circuits there would be but little trouble from electrolysis. The pipe-owning companies should co-operate with the railway companies by affording them access to their pipes for making necessary measurements, etc. After a railway company has installed a reasonable and fair return circuit it sometimes happens that it is desirable to eliminate any remaining current on pipes by the use of properly located insulating joints. Under these circumstances the pipe-owning companies should be willing to co-operate with the railway company in the installation of such joints.

In the decree recently filed in the celebrated Peoria case the railway company is enjoined and restrained from injuring the property of the water company by electric current escaping from the rails or structures of the railway company. No particular method for preventing escape of current is prescribed in the decree, because the court in its decision has already stated that a court does not have the power to prescribe by injunction any specific system, and that this power resides only with legislative bodies. In its decision the court, however, lays great stress upon the insulated radial return feeder system, which is spoken of as a quadrilateral system. The decree also requires the water company to co-operate with the railway company to the extent of giving the railway company access to its piping sys- [illegible] system, and of determining whether injury from electrolysis [illegible] determine whether it is complying with the terms of the [illegible]

It is evident from this decree that the expense of providing a proper return circuit for the railway system so as to minimize escape of current falls entirely upon the railway company, as it should in all fairness. One section of the [illegible]

as to prevent as much as possible the escape of stray electric currents from its system. If, after this has been done, it is found that stray currents still exist on the piping system, then the railway company may apply to the court for a hearing to determine whether the water company should be directed to permit the railway company to try a drainage system as an experiment to remove the remaining current harmlessly.

A drainage system such as contemplated as a possible final measure by the Peoria decree, when properly controlled so that only small currents are drained from the pipes, does not have the objectionable and dangerous features of promiscuous bonding where large currents are made to flow on the pipes, as often found in American cities, and may even be a safe final method where the soil conditions are favorable and where the underground structures are all continuous electrical conductors. It nevertheless seems to the author very unfair that any pipe-owning company should be compelled by a court order to permit an electric railway company to use its pipes as a return conductor for its railway system, even to the slightest extent. If the court does not have the power to compel the railway company to adopt any specific method for eliminating the danger from electrolysis, then it certainly should not impose any specific method upon the pipe-owning companies. The latter may, for example, prefer to remove any small remaining stray currents by means of properly located insulating joints.

It is the author's firm conviction that such remedial measures as pipe drainage or insulating pipe joints should be used, if at all, only as a final measure and never until the return circuit of the railway has been improved so that only small amounts of stray current remain on the underground structures. This view appears to be entirely in accord with the Peoria decision, and is certainly in accord with the best engineering practice.

* * *

BRITISH COLUMBIA'S LUMBER INDUSTRY.

In the lumber industry trade is somewhat brisk, and conditions are healthy. Local demand is better, and orders are increasing in quantity from east of the mountains. For several months past, the output of logs in the coast camps has been almost fifty per cent. higher than for the same periods of last year, in May, for instance, the cut being 65,000,000, as against 45,000,000 a year ago. Yet there is no great surplus on hand. Prices are firm but loggers are looking forward to an advance. The coast mills are all busy, though in the interior activity is hardly average. Manufacturers there decided last winter not to cut extensively this year, preferring to wait until such times that so much lumber was not imported from the United States. Only about two-thirds of the mills are operating, though if the privy council upholds the decision of Mr. Justice Cassels, that lumber sawn twice must pay duty. There will be a distinct diminution in the importations from the western states. On the other hand, many of the mills east of the mountains are preparing to operate double shifts.

Activity is best shown by the new mills. The Empire Lumber Company, which will develop limits at Cowichan Lake, Vancouver Island, has a capital of $7,500,000, New York people being mostly interested, and are getting ready for business. The capital of the Canadian United Lumber Company is $4,000,000, and the operations planned are on a more extensive scale, this company has taken over three mills in the Kamloops district, and will erect two more in the same section, one at Coquitlam and two on Vancouver Island. Mr. Robert Marr has started a new mill near Princeton. The South Vancouver Lumber Company has a new establishment just east of Eburne, on the Fraser.

"THE CANADIAN ENGINEER" IN MONTREAL.

In pursuance of the policy of *The Canadian Engineer* to strengthen still further its position in all parts of Canada, a larger and more convenient Montreal office of this journal has been opened at Rooms 617 and 628, Transportation Building, in that city. The importance of Montreal in the engineering and contracting life of Canada cannot be overestimated. Our realization of that fact prompts the present provision of greater service by this journal to Montreal interests. Mr. T. C. Allum, well known throughout the city, will continue as editorial representative, and will, as heretofore, keep our readers in the closest touch with all important developments. A file of *The Canadian Engineer* has been provided for the use of citizens and visitors, who are also invited to make every reasonable use of this branch office.

Special arrangements have also been made for the convenience of those who desire to consult plans and specifications of projected work throughout Canada. The new telephone number is Main 8436.

THE INTERNATIONAL ROADS CONGRESS OF 1913.

We noted in a recent issue that the third International Roads Congress would be held in London, England, in June, 1913. The first was held in Paris, 1908, and the second in Brussels, 1910, and in the future the Congresses will be held triennially. The object of the Congress is to collect, discuss and circulate all the latest scientific knowledge with regard to the construction and maintenance of highways. Mr. W. Rees Jeffreys, the secretary of the Road Board of Great Britain, a Government body which is responsible for the building and maintenance of roads in conjunction with local authority, is now in Canada as the representative of the International Roads Congress to arouse interest in next year's meeting. His aim is to secure as large and as representative an attendance from Canada as possible. Already over thirty governments have intimated to the British Minister of Foreign Affairs their intention of taking part officially in the Congress. In an address to the Ontario Motor League directorate Mr. Jeffreys laid emphasis on the waste of money resulting from slipshod methods of road construction, and we agree with him, for the present deplorable state of many of our roads throughout Canada are due primarily to the lack of judgment in putting down the right class of road for the traffic conditions. A great impetus would be given to interurban motor traffic if roads which could be used by heavy carrying trucks were built. It would in a measure solve the present railway traffic congestion.

There is little question but that a good deal of education must be given and public interest aroused before conditions can be improved here. The sentiment of the Provincial Government of Ontario towards the good roads question is shown by their recent action in refusing to meet the vote of the city of Toronto with a grant of $30,000 towards putting down a class of pavement more fitted for the traffic conditions on the roads leading into Toronto. It is to be regretted that an opportunity like the above should have been turned down by the provincial authorities. It shows very clearly that meetings like the International Roads Congress are most useful in spreading a knowledge of the resulting benefits from proper road facilities. We are pleased to note that the Dominion Government has appointed the Hon. Frank Cochrane as their representative to the Roads Congress for 1913. We sincerely hope that this action will be followed by the several provincial authorities throughout the Dominion, and we believe that results would justify the appointment of delegates from the different county road boards and the cities and towns throughout the country.

CONSULTING ENGINEERS WANTED.

We note in the daily press the following advertisement: "Applications from consulting engineers will be received by the Advisory Industrial Committee of the Toronto Board of Education to instal the power, mechanical equipment, heating, ventilating, illuminating, plumbing, and other appliances in connection with the new Technical School of Toronto. Applications to be addressed to the Secretary-treasurer, Board of Education, City Hall, and to be sent not later than July 2nd, 1912."

The mental capacity of the Toronto Board of Education is exhibited very well by the above. They are accustomed to call for tenders for the material used in the construction of the buildings, so naturally they call for tenders for the engineering knowledge necessary to design and equip the new Technical School. All that is needed to complete the above advertisement is the statement: "The lowest tenderer not necessarily accepted." It would be natural to expect that should one of the Board desire expert medical services he would insert an advertisement, stating the nature of the trouble, and asking for applicants for the position of medical consultant. Or if a lawyer were needed for certain legal advice, naturally the Board, or its individual members, would turn to the publicity of the daily press, and, by soliciting competition between members of the profession, secure the needed advice and the lowest possible market figure for the same.

No doubt applications will be received in answer to the above; and the Board, exercising their accustomed business acumen, will choose the tenderer whose price looks reasonable to them. The city, however, will eventually pay, and pay well, for such methods. The consulting engineers in Canada who take on the class of work outlined in the advertisement are not very large in number, and, by enquiry, in a very short time the Board could have secured reliable information regarding the securing of a competent man. As long, however, as they proceed in the way they have done, the city can expect to pay the difference between expert engineering advice secured in a proper manner and plumber's experience obtained on the "lowest tender" principle, and the difference will be found on examination to be considerable.

THE NEW COMMISSIONER OF THE DOMINION RAILWAY BOARD.

Official announcement has been made that the Government has appointed Henry L. Drayton, K.C., of Toronto, as chief commissioner of the Dominion Railway Board, to fill the vacancy created by the death of the late Judge Mabee. This appointment will receive the unanimous approval of those interested in a capable and efficient Railway Board. It is well known that the efficiency of the Board depends almost altogether on the personality of its chairman. Mr. Drayton, as corporation counsel for Toronto, has succeeded in his [illegible] way in the fight for a square deal for the city with the different corporations, and it is for his ability as a [illegible] [illegible] there that he has been chosen for the chief commissionership. The Dominion Government has made no mistake in choosing Mr. Drayton, for we feel sure his judicial fairness, his executive ability, and his strong personality will make him no mean successor to the late Judge Mabee.

A BRIDGE FOR VANCOUVER ISLAND.

A British Columbia delegation has just waited on the Dominion Government to urge Federal aid for the proposed construction of a bridge to connect Vancouver Island with the mainland at Seymour Narrows on Butte Inlet. The Department of Public Works in the near future will undertake a survey of the situation to determine the feasibility and probable cost of the undertaking. It is understood that a previous survey was made about forty years ago by Sir Sanford Fleming, who at that time estimated the cost of bridging the Narrows at $18,000,000. The delegation informed the Government that they believed with modern methods of construction the bridge could now be built for about $15,000,000. They urged the Government to undertake the work in order that Vancouver Island might have railway connection with Eastern Canada. It was further pointed out that no single transcontinental line could undertake a work of such magnitude alone, and that, therefore, the Federal Government should build one bridge available for all three transcontinental lines, charging a rental to each road on a mileage basis.

There is little question that, should the Government feel justified in committing itself to the project, it would mean a tremendous impetus to the development of Vancouver Island. The immense and now comparatively undeveloped resources there would immediately become capable of development. The engineering features of such a bridge from the point of view of design and construction would be of great interest if the Government decide to finance the work.

EDITORIAL COMMENT.

In last week's issue we published an article, entitled "Longest Reinforced Concrete Arch Bridge in the World." Unfortunately we omitted placing the author's name in the text. Mr. V. Elmont, of Westmount, Que., very kindly compiled the article for us, and we are glad to make this correction here.

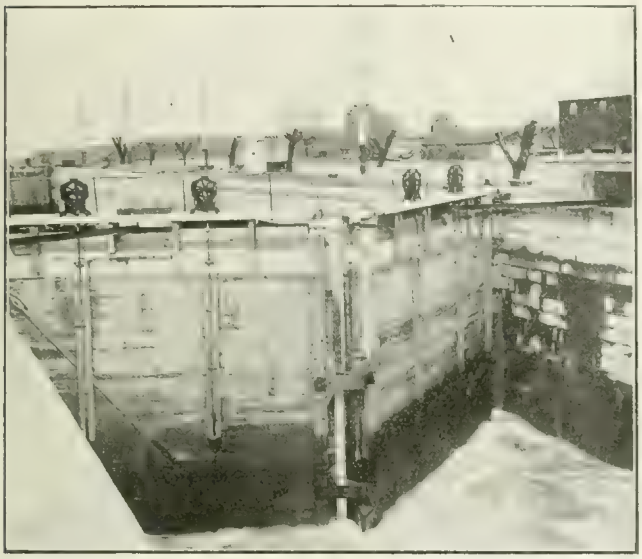
We note considerable criticism in the daily press concerning the expenditure of the highway improvement vote in Saskatchewan. Statements are being made to the effect that the appropriation is being used for political purposes. No doubt much of this talk is of a pre-election nature. At the same time it is to be hoped that the Government will deal fairly with this money, for they have a magnificent opportunity to illustrate the benefit to be derived in the building of bridges and good roads for the opening up of the country.

* * *

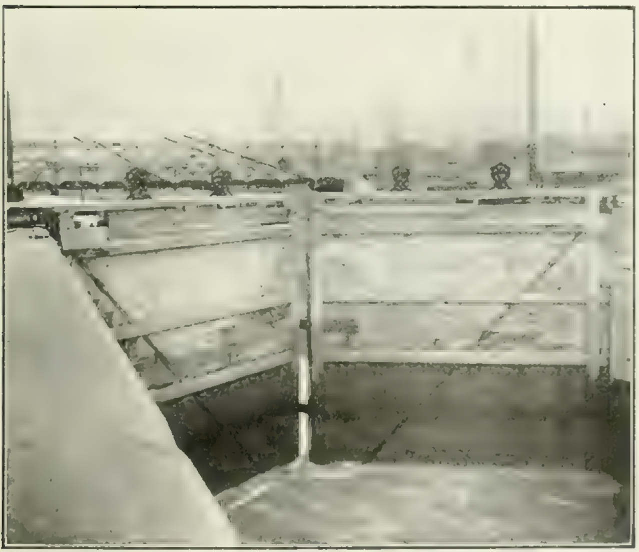
Toronto is at last awaking to the necessity for placing overhead electric wires underground. The Board of Control has arranged a conference with Premier Borden pending an application to the Dominion Railway Board, to compel all Dominion companies having overhead wires in the down-town section placed underground. We doubt very much whether any other city in Canada is in as bad condition from overhead wires as Toronto, and it is high time that definite action was taken for the removal of these wires. Montreal has done a great deal during the past two years to improve conditions there, and the extraordinary growth of Toronto justifies immediate action.

A SAFETY DEVICE FOR PROTECTING LOCK GATES.

The problem of protecting canal lock gates from possible injury from vessels is most important. A device which has been used very successfully on the Welland Canal is the Gowan safety device. It might be explained that miter gates in a lock consist of two leaves or wings, one hinged on either lock wall, which, when closed, rest against a sill on the bottom of the lock and against each other along the miter joint. When the pressure of water is against these leaves their safety depends on the miter joint being held intact. In case of a vessel coming up-stream and striking one of these leaves, as shown in the sketch, it forces this leaf back a short distance; and with the ordinary miter joint, the moment this leaf is forced back the support for the opposite leaf which rested against it is removed and the pressure of water upsets it. The pressure of water now forces the first leaf (and the vessel) down stream, and it also upsets.



Front View of Gates, Showing Cowan Safety Device.

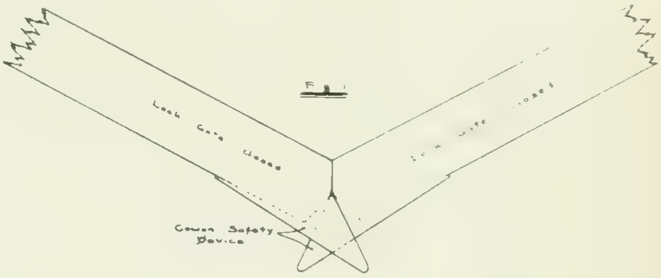


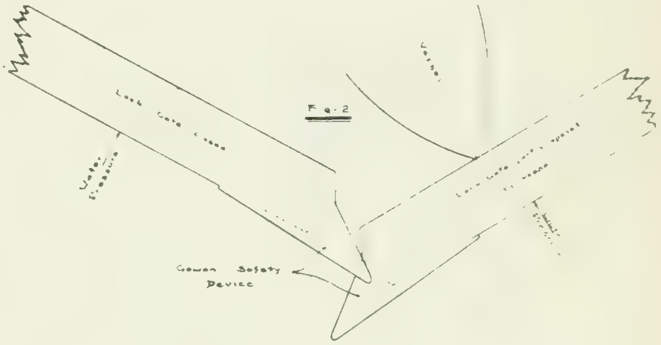
Rear View of Gates, Showing Cowan Safety Device.

The Gowan safety device, as applied to the existing gates on the Welland Canal, consists of four very strong cast steel fingers, two on each leaf, one towards the top of the leaf and the other towards the bottom. These fingers project a couple of feet beyond the miter, and, as will be seen from the sketch and photograph, one leaf can be pushed back very nearly the full length of the finger, but still give support to the opposite leaf.

Vessels rarely hit the lock gates with any great speed, and it is anticipated that this device will prevent a large majority of accidents which would otherwise occur.

The fingers are placed on the leaves, as shown, those on one leaf fitting in between those on the opposite leaf. This will prevent one leaf from jumping off its pivot when the other one is struck, as usually happens, the upward water pressure on the bottom of the gate being sufficient to lift it.





We are indebted to Mr. J. L. Weller, engineer-in-charge of the Welland Canal, for the above information, and for the use of the sketch and photographs. It might be added that it was through Mr. Weller's efforts that the safety device has been installed there..

ELECTRICITY vs. STEAM FOR WATER PUMPING.

Some interesting figures are shown by a comparison of the cost of pumping water by electricity and steam in the city of Woodstock, Ont. A short time ago the pumping facilities were changed so as to employ the power furnished by the hydro-electric commission.

In January, 1911, there was pumped by steam 46,494,000 gallons of water with the use of 145 tons of coal at a cost of $3.15 per ton. In January, 1912, there was pumped 40,400,000 gallons. The coal used in this month was 18 tons for heating purposes only. In February, 1911, the amount of water pumped was 43,484,000 gallons with 136 tons of coal, as against 38,000,000 gallons in February this year. In March the record shows 48,524,000 gallons last year with 151 tons of coal, and 40,000,000 gallons for March this year. The water is pumped against a head of about 100 pounds pressure.

The actual figures for the electrical operation have not as yet been computed, but it is estimated that the cost will be reduced by about $2,000.00 per year.

Woodstock pays $29.16 per horse-power, including a charge of $3.16 for stepping down expense.

THE ELECTRIC FURNACE AS A MEANS OF PRODUCING IMPROVED STEEL.*

By W. R. Walker.†

In the manufacture of steel by either the Bessemer or open-hearth process, it is very difficult to remove the last traces of oxygen. In the basic Bessemer process the overblown metal, which is an extreme case of oxidation, contains only [illegible] per cent. oxygen. Oxygen in combination with carbon (carbon monoxide), silicon, iron, aluminum and manganese, and also the combinations of silicates with these oxides, are very deleterious in steel.

My investigations lead me to believe that in the manufacture of steel for the so-called heavy products and steel that is produced in large quantities, a combination of either the acid or basic Bessemer converter and the electric furnace will take a very prominent place. With this combination it is possible to produce steel extremely low in oxygen and other impurities at a cost that will not be prohibitive.

At the present time there are over seventy electric furnaces of various types producing electric steel in Europe and America. These range in capacity from 1 to 15 tons. There is now under construction in Germany a furnace of 25 tons capacity. A number of these furnaces are competing successfully with crucibles in the manufacture of very high grade steel.

Generally speaking, electric furnaces may be divided into two groups: (1) Induction furnaces, in which the heat is supplied by a current induced in the bath; (2) arc furnaces, in which the arc is struck either between an electrode and the metal in the bath, or between two or more electrodes so as to heat the metal only by radiation from the arc.

In operating the electric furnace at the present time the most prominent methods or combinations are as follows:—

(1) Oxidation of silicon, carbon and manganese in an acid-lined Bessemer converter and removing the phosphorus in the basic-lined electric furnace with an oxidizing slag and then recarburizing, and with the aid of manganese and carbon and a new reducing slag removing oxygen and sulphur and dead melting as in the crucible process.

(2) Removal of silicon, carbon, manganese and phosphorous in a basic-lined Bessemer converter, and further removing phosphorus (if desired) in the basic-lined electric furnace with an oxidizing slag, and then with the aid of manganese and carbon and a new reducing slag removing oxygen and sulphur and dead melting as in the crucible process.

(3) Removal of silicon, carbon, manganese and phosphorus in the basic open-hearth furnace and then recarburizing, and in the basic-lined electric furnace with the aid of manganese and carbon and a new reducing slag removing oxygen and sulphur and dead melting as in the crucible process.

(4) Melting of cold scrap of inferior quality in a basic-lined electric furnace; removing phosphorus with an oxidizing slag and then recarburizing, and with the aid of manganese and carbon and with a new reducing slag removing oxygen and sulphur and dead melting as in the crucible process.

(5) Melting high-grade materials in the electric furnace and dead melting as in the crucible process.

The phosphorus is removed in the basic electric furnace in the same manner as in the basic open-hearth furnace—that is, by the use of lime and oxide of iron—and the resulting slag containing the phosphorus is removed and a new slag formed consisting of burnt lime and fluor spar; when the slag is melted, coke dust is added, which, coming in contact with the lime in the slag and the electric arc, produces carbide of calcium. The free carbon, and possibly the carbide of calcium in the slag, with the aid of carbon and manganese in the bath, eliminate the oxygen from the steel.

As compared with the Bessemer and basic open-hearth process, the electric has the following advantages: (1) The more complete removal of oxygen; (2) the absence of oxides caused by the additions, such as silicon, manganese, etc.; (3) the production of electric-steel ingots of eight tons in weight and smaller that are practically free from segregation; (4) reduction of sulphur to 0.005 per cent., if desired; (5) reduction of phosphorus to 0.005 per cent., as in the basic open-hearth process, but with the complete removal of oxygen.

As evidence of the reducing properties of the slag in the basic electric furnace, it has been found that if oxide of manganese and oxide of iron are thrown on the molten slag, the oxides are reduced to the metallic state and the reduced metal goes into the bath. Blown metal from the acid Bessemer converter, containing only 0.10 per cent. to 0.20 per cent. manganese, has been completely deoxidized in the electric furnace without addition of manganese or aluminum, the usual amount of silicon being added in the steel ladle. Rails made from this steel are now in service. The composition of one heat of this steel is as follows:—

	Per cent.
Carbon	0.55
Manganese	0.13
Sulphur	0.017
Silicon	0.19
Phosphorus	0.022

These rails are comparatively soft, but are showing superior wearing qualities compared with the Bessemer rails in the same track and under the same service conditions.

Electric-steel ingots crack much less in rolling than either Bessemer or basic open-hearth steel. Cold electric-steel ingots, when heated and rolled into rails, roll extremely well.

At the present time there are approximately 5,000 tons of standard electric-steel rails in service in the United States. These rails have been in the track about two years. During the past winter some of these rails have been subjected to very low temperatures—in some cases as low as —52° F., and are being exposed to all possible conditions of severe service. It is too early to state much about the wearing qualities of these rails, but from present indications it would appear that rails made by the basic electric process can be made somewhat softer than by either the Bessemer or basic open-hearth process and still show highly satisfactory wearing qualities. Up to the present time we have not heard of any basic electric rails in use in this country being broken in service.

For experimental purposes I have had made a small tonnage of electric-steel rails, which have varied in analysis as follows:—

	Per cent.
Carbon	0.50 to 0.75
Manganese	0.15 to 0.80
Silicon	0.10 to 0.40
Phosphorus	0.02 to 0.06

On account of the wide variation in the chemical composition of this steel, it would be difficult, without going into considerable detail, to discuss the physical properties of these rails. It might be stated, however, that electric steel of a given tensile strength has a slightly greater amount of elongation than basic open-hearth steel, and that electric steel is somewhat denser than basic open-hearth or Bessemer steel.

---

*[illegible] American Iron and Steel Institute.

†Assistant to the President, United States Steel Corporation, New York City.

With the electric furnace it is possible to produce steel which, when magnified one thousand diameters, shows no oxides or slag enclosures.

As high-grade electric steel can be produced at a lower cost than crucible steel, there has been a gradual increase in the production of electric steel for certain purposes where crucible steel was formerly employed, and where it has been demonstrated electric steel can be successfully used. This increased production has not been so marked where the object has been the improvement of steel entering into products manufactured in large quantities where the expense involved for experimental work is very great, and where of necessity it takes several years to demonstrate if rails and other products made by the electric process are superior to those made by either the Bessemer or open-hearth process. From present indications it would seem probable that there will be a decided increase in the production of electric steel for these products in the near future.

DISCUSSION.*

Three years ago the 15-ton, basic-lined Heroult furnace erected at the South Chicago works of the Illinois Steel Co. made its first heat. It was then the largest electric furnace in existence, and as yet none of greater capacity has been put into actual operation, although there are a few 20 to 25-ton furnaces under construction in Europe.

Our purpose was to demonstrate whether it was feasible to successfully operate a large electric furnace and make electric steel in large tonnages. At the time the South Chicago furnace was started the electric furnaces used in the manufacture of steel here and abroad were small, running from a ton or less to five tons in capacity. The aim abroad was largely to find a process cheaper than the crucible. Our aim was to command a superior steel, and, if possible, at a cost that would permit of its use in such products as rails.

Our mechanical, metallurgical and other problems proved many, and our experience soon demonstrated that the conditions surrounding the successful operation of a large electric furnace were in many respects entirely different from those involved in the use of smaller units. For example, the demands of a 15-ton electric furnace proved to be far in advance of the art of manufacturing electrodes. Our necessities represented a requirement that the electrode manufacturers of America and Europe had not been called upon to meet, and it took much time and money before there was finally secured the 20-in. round amorphous carbon electrode now being used.

While in the application of the electric furnace to the metallurgy of steel there is usually embodied the preliminary removal of impurities by oxidation, the thermal and chemical conditions that obtain are unusually favorable to the final purification of the metal. Although it has proved perfectly feasible to make steel of superior quality from even low-grade cold material, the usual practice at South Chicago is to refine in the electric furnace full-blown metal from the Bessemer converter.

While the electric furnace at South Chicago has probably operated on a greater variety of products than any other furnace in the world, especial attention has been given to the production of electric steel for rails. The results have been most promising.

The steel, in teeming, lies much more quietly than is ordinarily the case with open-hearth or Bessemer. The ingots when split show a very solid metal, with a remarkable freedom from blowholes. The pipe, unless filled, is as deep as with openhearth or bessemer steel. Segregation is at a minimum, and the steel is exceptionally homogeneous. Chemically speaking, almost any result within reasonable limits can be obtained. Physically, the metal is more dense than either openhearth or bessemer. In its ultimate strength and elongation for the same carbon, there is but little difference between electric and openhearth steel in the higher carbons. In the lower carbons, electric steel has a tendency to a higher tensile strength and a possibly somewhat lower elongation.

Many etched sections of rails indicate that the steel from the electric furnace is peculiarly uniform in structure, and it appears to be exceptionally free from oxide and slag inclosures as partially determined by microscopic examination. In fact, such superiority as electric steel may have, probably largely lies in its relative freedom from oxygen.

How much there may be in the theory advanced by some that the characteristics of electric steel are partially due to the influence of the peculiar thermal conditions upon its molecular structure, I cannot say. Certain indications, however, point to there being more in this hypothesis than is generally recognized.

We have, thus far, received no report of any breakage from the 5,600 tons of standard rails that we have shipped. Some of these rails have been in track for two and a half years or more. Some of the first rails that we produced were intentionally made upon the soft side, running as low as 0.55 per cent. in carbon. Our later electric rails, of which the laboratory results would indicate a relatively better wearing quality, have been made ten or more points higher in carbon.

On account of the comparatively short time that the electric rail has been in service, any statement in respect to its comparative quality is open to question. Of course, the final verdict on the merits of any steel must be in that metallurgical court of last resort—result in service. But whatever may be the verdict, American steel practice and the public must be the gainers from the extensive work that has been done in the endeavor to produce, through the electric furnace, a rail of superior quality.

---

OUTLOOK FOR RAILROAD EARNINGS.

By H. M. P. Eckardt.

The gross revenues of the Canadian Pacific Railway for March, 1912, were $10,389,000, as compared with $8,648,000 in March, 1911, and $7,667,000 in March, 1910. The increase in 1912 over 1911 therefore amounts to $1,741,000, or over 20 per cent., and the March, 1912, figures represent an increase of 35½ per cent. over March, 1910. Canadian Northern's traffic for March, 1912, was $1,572,700, representing an increase of $302,100, or about 20 per cent., over 1911, and an increase of $638,700, or about 68½ per cent., over 1910. Taking these two Western roads together, their gross earnings in the month just ended amounted to $11,961,000, which figure represents a gain of $2,043,000, or 20 per cent. over 1911, and a gain of 39 per cent. over 1910.

As the Grand Trunk earnings for March exceeded $4,000,000, the gross traffic receipts of the three systems amounted to about $16,000,000. These receipts are all passed through the bank accounts of the companies. So their average daily deposit with the banks in March would approximate $700,000, taking no account of interest on their investments and other income distinct from the freight and passenger receipts. With especial reference to the Western roads it is difficult to see how they can do other than continue to report satisfactory increases during the remainder of the calendar year. In an interview in The Monetary Times on August 6th, the Winnipeg manager of the Canadian Bank of Commerce says, "Everything points to the coming year as being the best we have ever had. * * * Speaking of prosperity, we need only consider the thousands of immigrants who are to enter Canada from both the Old Country and from across the border to realize that it would hardly be possible for anything but a successful year to follow."

There is no doubt that this remark applies with especial force to the business of the railways operating in Western Canada. It might almost be said that the immigration movement alone promises to ensure an eminently successful year for the railways.

Thus, taking the movement from the British Isles, it is well known that the Canadian Pacific and Canadian Northern steamships will derive a large revenue from the ship loads of European immigrants which they discharge at Halifax, St. John, and Montreal. There is not only the passage money across the ocean, but the passage money for the long land journey from the seaports to the Western points. In the case of the movement of American farmers the direct and immediate benefit experienced by our railways is more pronounced. For these settlers bring with them horses, cattle, implements, and effects by the train load. So with a promised movement of 400,000 or 500,000 new settlers into Canada in 1912, it would appear that prosperity for the railways was reasonably assured.

One may get some idea as to how these newcomers benefit the transportation companies by supposing that all of them settled in new towns or cities by themselves. An immigration movement of 400,000 would suffice to create 40 new cities of 10,000 population, or one immense city the size of Montreal. when one considers what an immense amount of freight has to be moved annually in order to supply Montreal's needs it becomes clear that the 1912 newcomers will minister most importantly to the prosperity of the railways.

A good farmer with a sufficient working capital will, with his family, create far more traffic for the railways than will the average family settling in a city. The farmer and his family create more traffic as consumers as well as producers. But, fortunately, one does not have to look solely to the immigration movement for indications of prosperity. Another thing which should help the Dominion is the revival of industry and trade in the United States. Depression has been more or less in evidence across the boundary line for a considerable time; and now there are signs of decided improvement. When the United States are prosperous Canada always derives considerable benefit.

Another auspicious development is the ending of Britain's labor troubles. It will be a little while before the real significance of this event is appreciated. But there is no doubt that the labor leaders saw distinctly that persistence [illegible] to paralyze the trade of the country was fast [illegible]. This with the almost complete exhaustion of many labor unions' funds seems to point [illegible] important labor troubles. At any rate, British finance is now rising hopefully and confidently from the depression in which it has been in-[illegible]. And [illegible] presume that sound Canadian enterprises would receive a better welcome in London.

Our borrowings in London also minister importantly to [illegible] of the Canadian railways. For the [illegible] imports of merchandise of one [illegible] there is the Western [illegible]. Last year 10,000,000 acres were seeded to wheat in the three prairie provinces. Whether this area is increased or not depends largely on the climatic conditions prevailing in the spring months. Fall plowing was interfered with late in 1911 by unfavorable weather; and the farmers are said to have entered the spring season handicapped on that account.

On the other hand there are this year 20,000 more farmers at work in these provinces. Some of them are farming on a big scale. Whatever may be the fortunes of the crop it will probably create much traffic for the railways—before and after it is harvested. Finally, the transportation of construction materials required for new mileage now under way promises to bulk importantly in the accounts of the railways. These and other considerations doubtless have played their part in creating and strengthening the optimism with which the securities of the representative railways are now viewed.

THE PUBLIC HIGHWAYS ACT OF SASKATCHEWAN.

The following is an abstract of the Public Highways Act of Saskatchewan, passed on March 15th, 1912.

There shall be expended annually under the provisions of this Act such sums as may be determined upon from time to time by the Lieutenant-Governor-in-Council, but not exceeding in the aggregate the amount voted by the Legislative Assembly for the purpose.

For the purpose of carrying out the provisions of this Act there shall be a board to be styled "the board of highway commissioners" consisting of three members to be appointed by the Lieutenant-Governor-in-Council, one of whom shall be appointed as chairman; the said commissioners shall receive such remuneration and perform such duties in addition to the duties assigned to them by this Act as may be determined by the Lieutenant-Governor-in-Council.

There shall be associated with the board for advisory purposes a committee consisting of two members to be appointed annually, one by the executive of the provincial organization representing rural municipalities and the other by the executive of the provincial organization representing urban municipalities. The members of this committee shall receive for attendance at meetings at which they are requested to be present by the chairman of the board such per diem allowance and travelling expenses as may be fixed by the Lieutenant-Governor-in-Council.

It shall be the duty of the board and it shall have power:

To lay out, plan and determine upon a system of public highways for the province which system may from time to time be altered or modified as the board may determine;

To determine upon the most feasible and economic methods for constructing, improving and maintaining public highways;

To furnish the officers of municipalities with information respecting the construction, improvement and maintenance of public highways;

To appoint such engineers, inspectors and officers as are necessary for the proper carrying out of the duties of the board and the provisions of this Act. All such appointees shall receive such remuneration as shall be determined by the Lieutenant-Governor-in-Council.

To inquire into and to report from time to time to the minister upon such matters as he may direct;

To report annually to the minister upon all work done and moneys expended under their direction as provided by this Act.

Subject to the approval of the minister the board may expend such sums of money as it may deem advisable upon the construction or improvement of any public highway and may also enter into any contract or agreement with any person, company or municipality for the construction or improvement of any such highway; the minister shall before approving of any such expenditure, contract or agreement, require the board to furnish him with such plans, specifications, estimates and other information as he may deem necessary respecting the proposed work.

For the purpose of the better carrying out of the provisions of this section the Lieutenant-Governor-in-Council may from time to time make such general regulations as may be deemed advisable regarding the expenditures to be made by the board on public highways.

All the provisions of The Public Works Act concerning the entering upon and the expropriation of lands required for public works shall apply to any works carried on or proposed to be carried on by or under the direction of the board and for the purposes of the said entry and expropriation the board shall have all the powers conferred upon the minister by the said Act.

The minister shall submit annually to the Legislative Assembly within the first fifteen days of the session thereof a report containing a statement of the work done and the money expended under the provisions of this Act.

The Lieutenant-Governor-in-Council shall have power to make any provision not inconsistent with this Act which may be required for the better carrying out of its provisions.

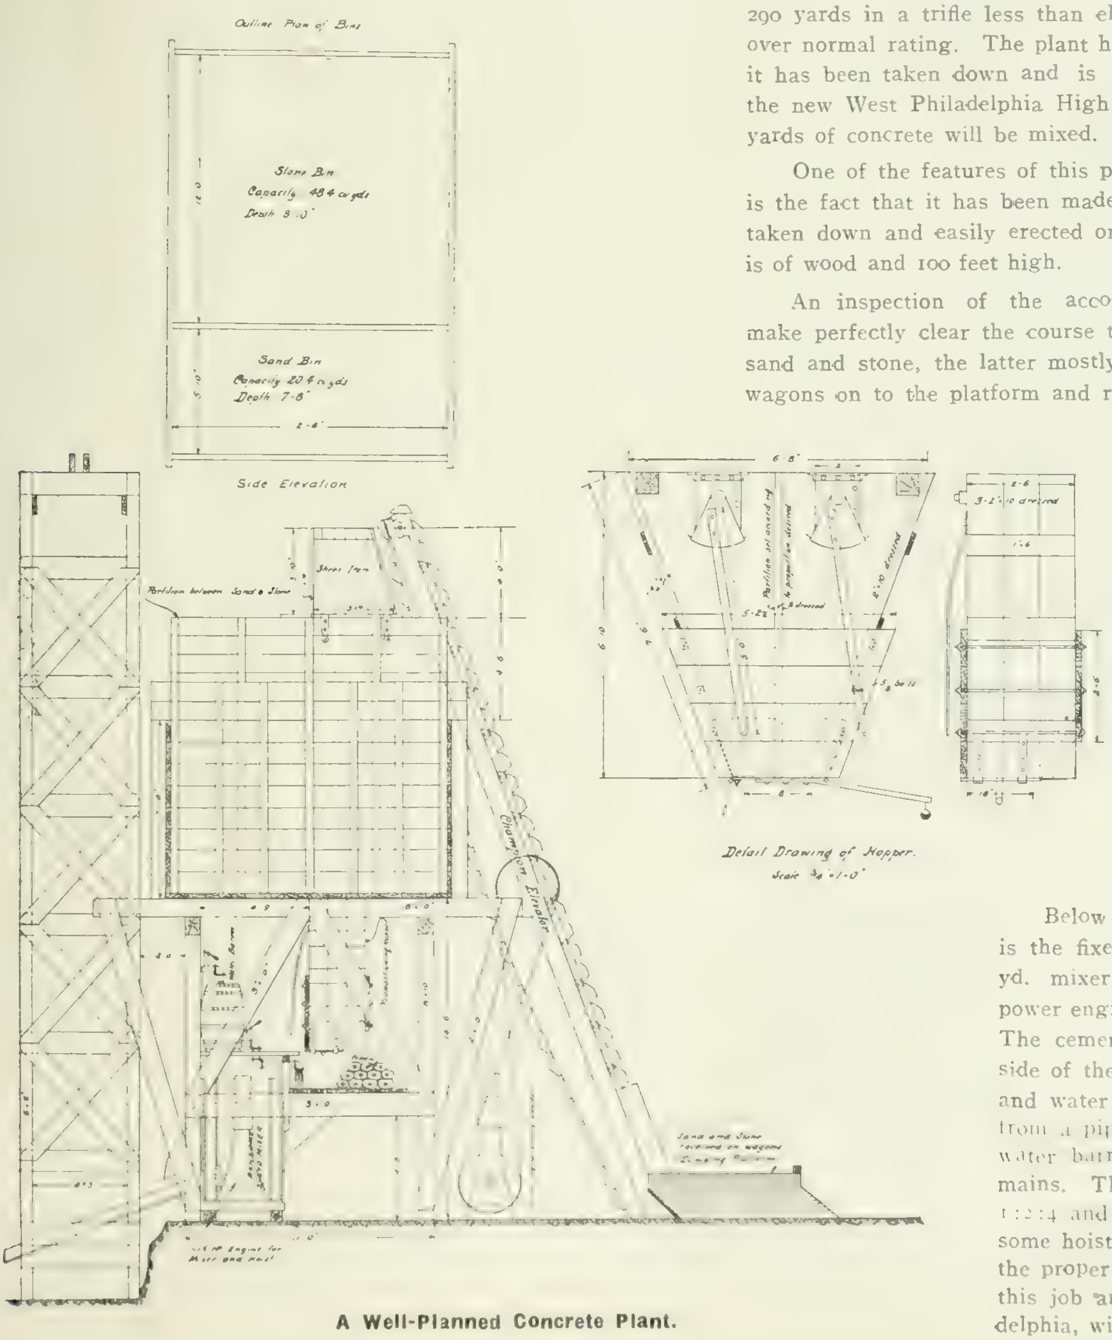
A WELL-PLANNED CONCRETE PLANT.

A plant lay-out which would be very suitable for buildings where about 10,000 cubic yards of concrete are to be placed is that which was employed in building the American Can Company's new reinforced concrete factory, located on Beach and Palmer Streets, Philadelphia. This building is five stories high with basement, and has over-all dimensions of 346 by 100 feet. The ¾-yard Ransome mixer has turned out 9,200 yards of concrete for this work, at times mixing 290 yards in a trifle less than eleven hours or 25 per cent. over normal rating. The plant has been so satisfactory that it has been taken down and is being used in constructing the new West Philadelphia High School, where about 8,000 yards of concrete will be mixed.

One of the features of this plant outside of its economy is the fact that it has been made so simple that it can be taken down and easily erected on another job. The tower is of wood and 100 feet high.

An inspection of the accompanying illustration will make perfectly clear the course the materials follow. The sand and stone, the latter mostly ¾-in., are dumped from wagons on to the platform and raised by a bucket elevator, driven by a 10-horse-power engine, to the sand and stone bins at the top. The stone bin has a capacity of about 48 yards, while the sand bin holds about 20 yards. From this point the aggregate fall by gravity into a proportioning hopper being admitted through gates. The hopper is provided with a partition that can be set according to proportion desired.

Below the proportioning hopper is the fixed batch hopper of the ¾-yd. mixer operated by a 15-horse-power engine that runs the hoist also. The cement is piled in bags alongside of the top of the mixer's hopper and water is turned into the latter from a pipe leading from a marked water barrel connected to the city mains. The concrete is proportioned 1:2:4 and is discharged into a Ransome hoist bucket that is unloaded at the proper point. The contractors on this job are Cramp & Co., of Philadelphia, with F. V. Warren in charge.



A Well-Planned Concrete Plant.

ICE TROUBLES AT BUFFALO.*

By Henry L. Lyon.†

The city of Buffalo takes its water supply from Niagara River and Lake Erie and pumps it direct into the city mains. The source of supply is unlimited, it is only a question of being able to get it to the consumers on time. The reservoir holds 116,000,000 gal., but is not at a sufficient elevation to supply more than half the city and would not supply that part satisfactorily for more than a few hours. The daily average consumption of the city is 135,000,000 gal. and at times it runs up to 200,000,000 gal. The reservoir on the low service and the water tower on the high service act as balance wheels in regulating pressure.

The old intake pier is situated about the middle of Niagara River and 1,000 ft. from the pumping station, which is situated on the bank of the river. The intake is built in the narrowest part of the river about 1 mile from the foot of Lake Erie. The current is from 7 to 15 miles per hour. The pier is connected to the suction canals, or wells, in the station by two tunnels under the river. One is 6 ft. in diameter, the other 6 x 12 ft. in cross section. The ports to admit the water are about 4 ft. above the bottom of the river and on both sides of the pier. The river at this point is 16 ft. deep, the bottom being a smooth limestone rock, with scattered boulders. On the sides of the pier are ice shields of steel (see Engineering Record, April 1, 1899) extending to 2 ft. above the bottom of the river, so that the water must come under the shields from the bottom of the river, not the surface; on the sides of the shields are gates that can be opened and closed so it is possible to take the surface water if ice closes the lower levels.

When ice is running down the river the current turns it over and over and churns it up, forcing large quantities to the lower levels so that the river is a floating mass of ice for its whole depth. When the lake becomes frozen over a certain phase of the ice trouble is over for the winter and does not reappear until the break-up in the spring.

The location of the pier, however, with a swift running river for a mile above so it cannot freeze over, makes an ideal situation for frazil, anchor, ground, and slush ice.

The swift current prevents a surface ice forming. The frozen ice surface in the lake protects the water underneath, as the cold air will penetrate water better than ice. When the water flows from under the lake ice the colder air will cause frazil and anchor ice to form. A heavy snowstorm will not melt readily when it falls into the cold water, but becomes waterlogged and forms slush.

The terms "surface ice," "anchor ice," "ground ice," "frazil ice," "pebble ice," "slush ice," are somewhat indefinite. In a great many cases it is impossible to tell the several kinds of ice apart after they have changed their original position or formation and become broken up and mixed. They then become [illegible] ice.

Surface ice is the form generally found on the surface of lakes and ponds, when their surface is frozen over. It forms first on the surface, as the cold air penetrates the ice and cools the water directly under the surface ice to a lower degree. It makes new ice, attaches to the upper ice and thus increases the thickness of the ice.

Anchor, or ground ice, will only form in a running stream on a clear, cold night, the air temperature being very near or below zero. It never forms under surface ice or in cloudy weather. It forms near the bottom of the river and attaches itself to rocks or other hard substances, preferably a dark substance. It loosens itself from the substance to which it is attached when the sun rises or the weather moderates. It is very buoyant and if stones or other things are imbedded in it will raise them and float them down stream. It has been known to raise and float abandoned anchors so they could be recovered by the owner or pirates. Small boats should look out for such conditions, because at times anchor ice rises in large masses and has been known to overturn such boats.

Frazil ice is only formed in swift running streams, where surface ice cannot form and then only in very cold weather. It forms best on a dark, windy day, or a clear, cold, windy night, when the wind is blowing against the currents. It consists of fine crystals sometimes very hard, and floats readily. When it, as well as anchor ice, is forced under surface ice and attaches to it and to its own particles, it will often fill up the whole bed of the stream and cause floods.

Anchor ice forms on the ports of the intake pier, so as to completely close them. The small particles seem to rise out of the water, like bubbles out of champagne, and attach to the sides of the openings, then to each other in lightning rapidity, until the whole opening is closed and cannot be broken by pike-poles. We then resort to small charges of dynamite.

Runs of ice of all the varieties, sometimes separately, more often all of them mixed into slush, get into the intake, pass down through the shafts and tunnels and then into the suction canals, or wells, in such quantities as to clog the pumps. At times the mixture is so solid that water will not pass through it to the pumps, and the pumps must be stopped entirely. If the ice is formed at a very low temperature, it is very difficult to melt.

At Buffalo there are revolving screens in the canals with which large bodies of the ice may be raised above the water and then melted with hot water and steam. At times there will be a hundred or more men dipping the mixture on to shelves or racks in the wells, above the water, with long-handled scoops, like minnow nets, but made of heavy wire, and then melting it with hot water and steam.

Niagara River for its full length, 35 to 40 miles, is too swift for surface ice to form, so that anchor and frazil ice form readily. It is this ice mostly that runs over Niagara Falls in such quantities that it banks up below the falls and forms each winter the ice bridge which becomes so solid that people walk over the river just a short distance from the falls. It was this same kind of ice that dammed up the mouth of the river and caused the big floods there a few years ago. The same kind of ice has caused the floods at Montreal in the middle of winter when there had been no rains or any warm weather to melt the snow, but the floating anchor and frazil ice had been carried under the surface ice in such quantities as to completely fill the bed of the St. Lawrence River and thus formed a dam over which the whole of the Great Lakes must flow.

The new intake pier at Buffalo is built at the head of the river and foot of Lake Erie in water 24 ft. in depth. The current at this point is only about 2 miles per hour. The lake freezes over up to and around the pier. It is believed that in the present location anchor and frazil ice cannot form; the surface ice will form only 15 in. in thickness and ice troubles are probably a thing of the past.

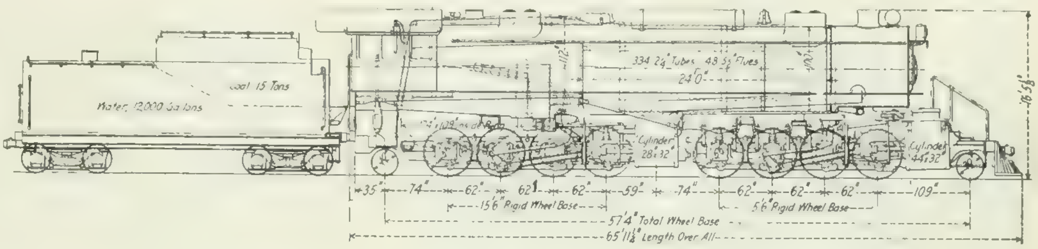
---

*Abstract of paper read before American Waterworks Association at thirty-second annual convention, Louisville, Ky., June 3-8, 1912.

†Deputy Water Commissioner, Buffalo, N.Y.

A NEW LOCOMOTIVE.

The American Locomotive Company is just completing for the Virginian Railway four Mallet compound locomotives that far outclass in weight and power even the largest of the most recently constructed big locomotives. The engine will weigh, in working order, 540,000, with 479,200 lbs. on drivers. The combined weight of the engine and tender will be 752,000 lbs. The total length of the engine over all is 65 feet 11¼ inches, and total length of wheel base, 57 feet 4 inches. These engines will have a tractive power of 115,000 lbs. or 60 per cent. more than the pioneer of this type built in America for the Baltimore and Ohio Railroad. By the American Locomotive Company's system of compounding, the tractive power at slow speeds can be further increased to 138,000 pounds by working the engine simple.



With two of these Mallets as helpers and a Mallet of 92,000 lbs. tractive power as a road engine, it is expected to take a train of 4,230 tons over a 14 mile, 2.07% grade. This grade is the ruling point on the entire line as all the tonnage passes over it. The road engine will then take the train unaided through to the terminal of the division.

Vanadium steel was used in the frames, crossheads, driving tires, all springs, main driving axles, main crank pins, centre of piston heads. Cast iron containing vanadium was used for cylinder castings, valve chamber bushings, piston bull rings.

Apart from the enormous weight and power of the locomotives, the dimensions of some of the principal parts are impressive as showing the extent to which all limits were exceeded in their design and construction. The following dimensions warrant special attention:

Outside diameter of boiler at front end	100″
Outside diameter of largest ring	112″
Tubes, number and diameter	344; 2¼″
Flues, number and diameter	48; 5½″
Heating surface, total	6760 sq. ft.
Superheating surface	1310 sq. ft.
Fire box ring	184½″ x 119″
Length of boiler	50′ 1⅛″
Low pressure cylinders, diameter and stroke	44″ x 32″
High pressure cylinders, diameter and stroke	28″ x 32″
Tender, water capacity	12,000 gal.
Tender, coal capacity	15 tons

◆

PURIFICATION BY COPPER SULPHATE.

In a paper before the Institution of Water Engineers of Great Britain, on the "Use of Copper Sulphate in Purifying Water Supplies," Mr. George Embrey described the measures taken for destroying plant-growth in the Witcombe reservoirs of the Gloucester Waterworks.

He said that his attention was directed to the reports of experiments made by the United States Department of Agriculture with copper sulphate, and in 1904 and 1905 numerous investigations were made to determine the amount which could be used for the destruction of the lower forms of plant life without destroying the fish or rendering the water toxic to human beings. It was found that quantities of 1 to 1,000,000 fulfilled these conditions, but quantities of 1 to 3,000,000 were sufficient to destroy the Algæ which were believed to cause the trouble. In 1908 permission was given by the Sanitary Committee to carry out an experiment at Witcombe reservoirs, which were at the time choked with "Chara Vulgaris." This plant was propagated by means of spores contained in an Archegonium, and fertilized by Antheridia from an Antheridium; the bursting of the Archegonium set free myriads of minute greenish cells, which, with the countless Anthrozoids, gave the water a distinct color and a fishy odor. In consequence of this odor it had been suggested that the particular Chara was a new species named Chara Fœtida, but the author did not find that the plant differed in any material respect from the well-known Chara Vulgaris, except in regard to the odor. This, however, was removed by washing the plants, and an examination of the washing water revealed the presence of numerous Spongilla Fluviatalis, which gave out a distinctly fishy odor. A portion of these was used to inoculate a nutrient agar medium, which, on incubation, yielded Proteus Vulgaris, an organism well known to evolve a fishy odor. The author therefore believed that this was the cause of the odor.

The author's method of applying the copper sulphate differed from that usually adopted, which was to place the crystals in a canvas bag trailed at the stern of a moving boat. The defect of this method was that the copper sulphate solution was very much diluted before it reached the bottom of the reservoir. This, however, was overcome by scattering the fine crystals over the surface of the water, as in sowing seed, the crystals falling rapidly to the bottom before dissolving. The sulphate was used in the form of a fine powder containing 98 per cent. of the salt, the present price of which was 28s. per cwt. The three reservoirs had capacities, when filled, of 60,000,000 gallons (No. 1) and 30,000,000 gallons each (Nos. 2 and 3), and for these 4 cwt. of sulphate was used, giving approximately a proportion of 1 to 3,000,000. Each reservoir was allowed to stand at least three days, and if convenient, a week, at the end of which period not a trace of sulphate of copper could be found in the water. The water should be treated in the early spring (about February), when the bottom was usually covered with diatoms only; in March and April the confervæ made their appearance, and later the Chara began to grow. It had been found that if the treatment was applied in the early stages the diatoms were destroyed, and neither the confervæ nor the Chara appeared.

After four year's experience the author could confidently say that the odor and color so frequently met with in reservoirs containing water collected from the Upper Lias and Inferior Oolite could be perfectly removed by the use of sulphate of copper, and that no danger need be feared if the operation were performed with care and under proper supervision.

◆

ALBANY'S TYPHOID DEATH RATE.

Albany's typhoid death rate in 1911, as reported by the Bureau of Water, was 15.8 per 100,000 population. The city is supplied with Hudson River water purified by sedimentation, double filtration and hypochlorite.

NEW GARBAGE INCINERATION PLANT.

The extensive plant shown in the accompanying illustrations is a garbage and refuse destructor erected in the city of St. Petersburg, Russia, by Messrs. Heenan & Froude, Ltd.,

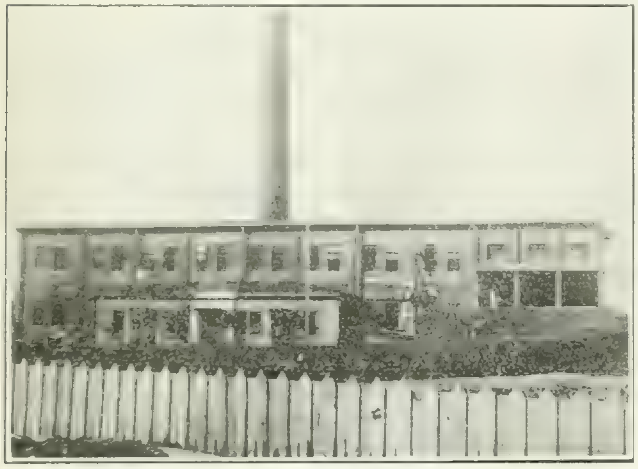


Fig. 1.—General View of Heenan & Froude Garbage Incineration Plant for St. Petersburg, Russia.

of Manchester, the parent company of Heenan & Froude of Canada, Limited, who are erecting somewhat similar plants for the same purpose in Ottawa, Moose Jaw, Calgary and Edmonton. The plant is designed to consume 150 tons per day

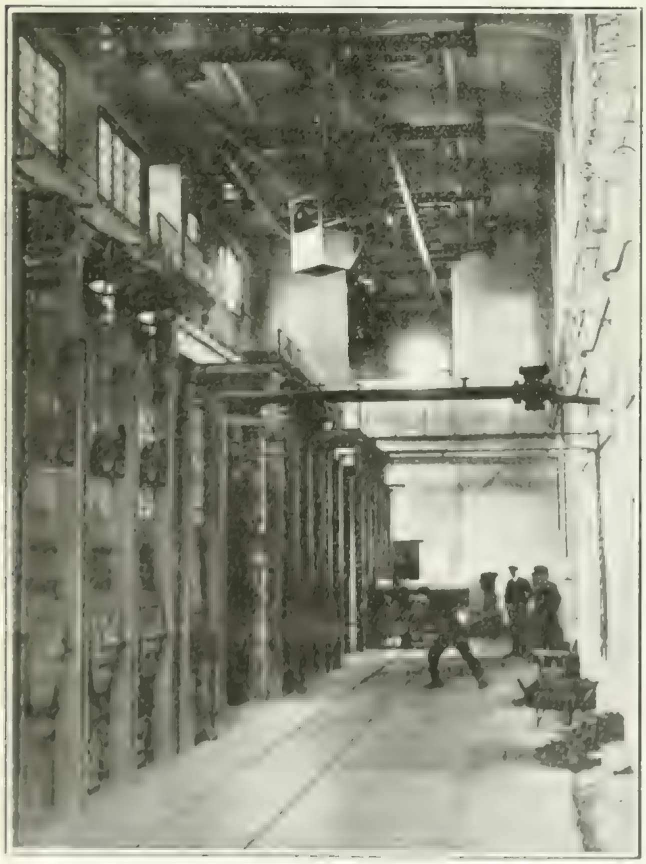

Fig. 2.—View of Clinkering Floor Showing Method of Withdrawing Clinker.

[illegible] of the furnace with a clinker truck opposite one of the grates in the rear of the room. A man is engaged turning a winch on this truck, which withdraws the whole of the clinker from the cell in one operation. As the illustration shows, this is easily performed by one man instead of requiring the laborious efforts of two or three as in the old style of clinkering.

The material to be consumed is charged into the furnace by means of a container opening into the top of the cell. These containers are shown in illustration No. 3. They are filled with material, the upper door is closed, and a door opening direct into the furnace is withdrawn by means of a winch operated from the clinker floor, and the contents are promptly precipitated into the furnace.

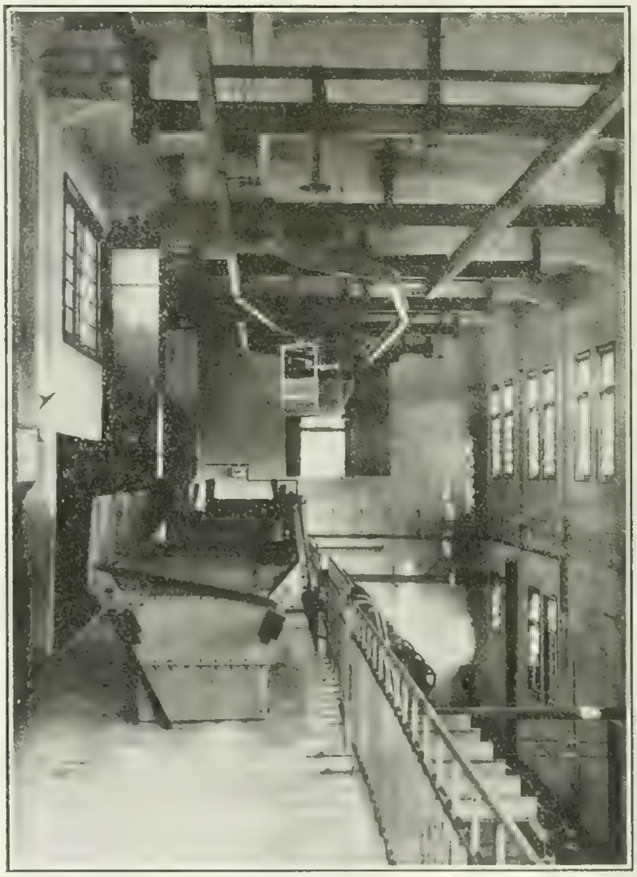

Fig. 3.—Charging Floor Showing Top of Containers from Which Refuse is Charged.

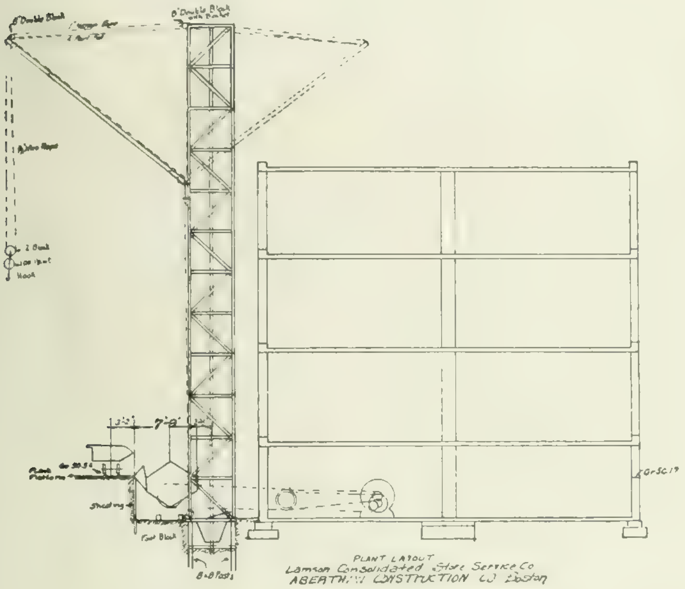
THE CONCRETE PLANT OF A FOUR-STORY MACHINE SHOP JOB.

During the course of last winter the Aberthaw Construction Company, of Boston, erected a four-story reinforced concrete machine shop at Lowell, Mass., for the Lamson Consolidated Store Service Co. This reinforced concrete building is 150 by 50 feet in plan and has brick curtain walls. The general policy of the contractors is to heat both the sand and stone in freezing weather. However, on this only the sand was heated, as the owners who provided the heat has not sufficient steam capacity to heat the stone also. The stone was received in cars, and while the car was on the siding precautions were taken to keep snow out of it by canvas covering. The sand was delivered in wagons and dumped directly onto steam pipes laid on the ground and furnished with a continuous supply of steam during the day time only at about 12 lbs. pressure. To supplement this the contractors used flexible rubber steam hose and iron pipes which were thrust into the sand heaps in specific places where there was reason to doubt the temperature of the sand. The water was heated by having a steam-pipe reaching to the bottom of the water barrel, and salt was added generally in the proportion of about 2 per cent. of weight to the amount of the cement used, the percentage being varied slightly as the temperature changed.



After examining the ground it was decided to place the mixer and hoisting tower at the north side of the building and to omit the building of one bay at the west end of the ground floor, so as to allow industrial cars with the coarse aggregate to be pushed through at the proper grade. Quick unloading chutes, extending from the side of the standard gauge cars were used, the material being dumped into a square-bodied dump car.

After being mixed the concrete was dumped into the Aberthaw hoisting bucket which is standard with this concern in all their construction work. The Aberthaw iron hoisting tower was used with the boom, moving the steel and centering to the upper floors. The distributing of the concrete was done with V-shaped Koppell cars, the length of carriage from the mixer to the point where it was placed on the job in question averaging less than 100 feet. The method of distribution with cars, which take an entire four-bag batch at one time, is very much more conservative in retaining the heat in the mass than when concrete is distributed in barrows. It should be added that salamanders were used after placing the concrete in each floor and the building enclosed in canvas floor by floor. The building was designed by Lockwood, Greene & Co., Boston.

* * *

BRITISH COLUMBIA'S RAILWAYS.

Sir Richard McBride estimates the amount to be spent in railway construction in British Columbia during the next four years at $100,000,000 and expresses the opinion that the expenditure will in all probability be over that amount. Mention of the figures brings one to a realization of what is being done and what is contemplated by the different railway companies that are anxious to do business on the Pacific seaboard. Activity is not confined to any one road, but to all of the four which already have lines in British Columbia, namely, the Canadian Pacific Railway, the Great Northern, The Canadian Northern and the Grand Trunk Pacific, and also the Pacific Great Eastern, which is reckoned practically as the Grand Trunk Pacific. Work was begun this week on the large pier of the Canadian Pacific Railway which will cost three-quarters of a million dollars, and excavation is proceeding on the site of the new depot. The Canadian Pacific Railway will expend more in British Columbia during the next few years than for many years past. The Great Northern will double track its lines between Vancouver and New Westminster.

Mayor Findlay's proposition is that the city prepare to take over the lines of the British Columbia Electric Railway Company within the city, according to the terms of the existing agreement, in 1918. The members of the greater Vancouver transportation committee interviewed the premier this week, and mayor Findlay made his pronouncement upon his return. "Since the company will not compromise in any way in the matter of consolidation of agreements the city said he should decide upon a fixed policy to acquire the lines by arbitration at the termination of the agreement with the city." This suggestion was made in the city council last year, and the proposal that passed then was that the city set aside $500,000 each year so that it would have something to start with in 1918. The uncompromising attitude of the railway company is winning many to the principle of municipal ownership of this great public utility. More would be in favor of the acquisition of the lines but for the reason that they believe, that some other method of transportation will have been evolved by that time, and that the people will not be dependent on a company that has a monopoly of transportation in whole of the lower portion of southwest British Columbia.

Vancouver has not had to trouble about its water supply, since there was plenty for every kind of use. Now that the city has grown, regulations are being enforced which people, accustomed to what prevailed previously, regard somewhat as a hardship. Residents in the outlying districts are sometimes practically devoid of water during the middle of the day, when it is required most. A large fire took place in South Vancouver this week and the supply of water there was insufficient. Such a condition will mean high insurance rates. The necessity of more water is presenting itself, a large watershed area in Seymour Creek Valley, above the city's reservoir might be secured and thus ensure the permanence and continuity of the supply. There is considerable timber on this area, and the owners have approached the British Columbia Electric Railway Company to construct a line to take the timber off. It is conceded that if this is done the water supply will be materially affected. Last fall the water committee took up the matter of purchase of these lands, comprising several thousand acres, and it was almost decided. The aldermen realize that the purchase must be made sooner or later. Half a million dollars or less will secure the whole of the watershed, timber, land and all, while if the city waits a few years longer double this amount will be required for the same purpose. The acquisition of this watershed has been recommended by the city engineer, the consulting waterworks engineers, in fact by all who have to do officially with the waterworks system.

One hears much of American enterprize and American aggressiveness but few companies have progressed so rapidly and expanded so widely as the Norton Griffiths Steel Construction Company, with British capital and Britishers conducting it. This concern has had the contracts for some of the largest and best buildings in the city, including the famous Burns block, and secured this week the contract for the construction of the new ten-story structure to be erected by Henry Birks and Sons at the corner of Granville and Georgia streets. The operation of a large company like this means the investment of considerable Old Country capital here.

ENGINEERS' LIBRARY

Any book reviewed in these columns may be obtained through the Book Department of The Canadian Engineer.

BOOK REVIEWS.

The Design of Mine Structures. By Milo S. Ketchum. Published by the McGraw, Hill Book Co., New York. Cloth: size 6½ x 9 inches; 544 pages; 77 tables; 300 illustrations in the text, and eight folding plates. Price $4.00.

It is a pleasure to record the publication of another book by Prof. Ketchum. His books are always examples of what technical treatises should be, and this volume is no exception to the rule. The design of mine structures is systematically discussed. While the design of headworks for mines is given the principal place, the design of buildings, bins, coal-washers and breakers is discussed very fully. Only the structural engineering side of the operation of mines has been considered and, therefore, the design of hoists and other machinery has been omitted. Statically indeterminate structures are briefly discussed, showing the application of the methods developed to the calculation of stresses in head frames. The methods for the calculation of stresses in simple frame structures and the methods for calculating the pressures on retaining walls and the stresses in bins are briefly discussed. Complete specifications are given for steel, timber and concrete mining structures. A brief resumé of the design of reinforced concrete is given in an appendix. While a good deal of the material appearing in this volume has appeared before in the author's other books, nevertheless the repetition has been justified. This volume is a self-contained, concise and valuable text book for the student, or the structural engineer who wishes to become familiar with the design of mine structures.

Reinforced Concrete Construction. Elementary course. By M. T. Cannell. Published by E. and F. N. Spon. 125 pages. Price $1.25.

This is a small book which has been gotten out primarily for those engaged in reinforced concrete design, who have a limited technical knowledge. A few pages are given to the construction of form work and the mixing and placing of concrete, also the nature of the ingredients. Several pages which are devoted to structural mechanics give bending moments, shears, abutment reactions, simple and continuous beams with various methods of loading. The design of reinforced simple beams, slabs, tee beams and columns are also taken up.

The book is another case of endeavoring to cover too great a subject in a small space, but it will be found useful for draughtsmen and superintendents unfamiliar with theory.

The Principles of Structural Mechanics. By Percy J. Waldram. Published by B. T. Batsford, London. [illegible] pages. Price [illegible].

This book is gotten out primarily to fill a long-felt want, namely, for a treatise on structural mechanics, which is not over-burdened with mathematics, also one that can be understood by engineers or architects with a limited technical [illegible].

The first part of the book deals with the theory of levers, and [illegible] beams, explaining the method of determining forces by graphical methods. A section is devoted to beams and cantilevers, giving various conditions of loading with methods of determining bending moments, reactions and shears. Another portion of the book is devoted to design of walls and foundations. Roofs of several different types are taken up, as are also arches, domes and columns. Material on beams is such as is available in almost any of the hand books, whereas there are very few books, with the exception of advance treatises, in which one finds as much about arches and domes as is contained in this book. For engineers engaged in design of various structures, especially arches, domes and special roofs, in which it is not necessary to go into advance theory, this book will be very useful.

The Heat Treatment of Tool Steel. By Harry Brearly. Published by Longmans, Green Co., London, England. 160 pages; 5½ x 8½; well illustrated. Price $2.50.

Of late there has been a great deal written on the heat treatment of tool steel. The main trouble in dealing with such a subject is to make one's information of practical value, but, unfortunately, as in many other departments, of engineering, those who are well informed practically, are either too busy or have no inclination to put into print what they know.

This book, written by a practical man, contains a great deal of well-written practical information. The theory of hardening and tempering has been well worked into the subject which, to say the least, is a relief to anyone at all accustomed to reading the tiresome learned discussions that appear from time to time. The illustrations also are excellent.

There are thirteen chapters in all, covering structure, fractures, forging and annealing tool steel, hardening and tempering, defective tools, hardening plants, pyrometers, case hardening, and a short discussion of alloy steels.

Anyone interested in the subject of tool steel should have this book.

Measurement of High Temperatures. Burgess & Le Chotelier. John Wiley & Sons, New York. Cloth; 510 pages; 6 x 9¼; illustrated. Price $4.00 net.

In the present day, the practical man has come to realize that the old methods of "judging temperature" are absolutely out of date, more so as the pyrometer has been brought to such a stage of perfection that anyone possessed of ordinary intelligence can operate it. This book has evidently been written largely with the object of helping engineers. The information has been very clearly put together, so much so that the book may be read by student, engineer or scientific investigator, and all three find his needs, the illustrations being very well suited to making the text clear.

The first three chapters deal respectively with standard scales of temperatures, gas pyrometry, and calorimetric pyrometry. Chapter IV. on thermoelectric pyrometers, is very complete. Next comes a description of electrical resistance pyrometers, following a thorough discussion of the laws of radiation. The radiation pyrometers are described, as are pyrometers in the next chapter.

The department of recording pyrometry, in which a great advance has been made of recent years, is very thoroughly gone into. This portion of the book, besides being of value to the student engaged in scientific research, is of interest to the practical man. One of the instances given where the value of having these instruments in works is that of an annealing oven fired by an old and new hand, the record showing how the more experienced hand saves time and money.

A final chapter treats of the standardization of pyrometers, etc. The bibliography of 24 pages is very extensive. The authors are to be congratulated upon the conciseness of their explanations, the long theories being well isoalted in such a manner as to give no trouble to the reader not interested in "such dry information." The book, in fact, "gives results."

The Transit Theodolite, and Other Instruments Mechanically Considered. By H. W. Vallé. Published by the author. Cloth; 4 x 6½ inches; 76 pages; illustrated. Price $1.00.

Mr. Vallé was for twenty-three years instrument maker to different firms in England, and is, therefore, well-qualified to write on the subject of instruments. This little volume has been written for the purpose of assisting surveyors, engineers and others in those difficulties associated with their instruments where help has not hitherto been forthcoming. The adjustments of the different instruments are covered very thoroughly and their general design is thoroughly discussed.

Engineering Directory, 1912. Published by the Crawford Publishing, Chicago, Ill. Cloth; size 4 x 6¾ inches; 1496 pages. Price $5.00.

The book aims to be a complete directory of the plumbing, heating, lighting, power plant and mill supply industries in the United States. It contains a list of wholesale dealers in plumbing, heating and lighting supplies; list of jobbers and dealers in mill, steam, mine and railway supplies, tools and machinery and in addition there are reliable mailing lists of waterworks and gas companies power plants, wholesale dealers in hardware and in electrical supplies and purchasing agents of railroads. The book will be found invaluable to the manufacturer and the engineer.

Modern Illumination Theory and Practice. By H. C. Horstmann and Victor H. Tousley. Published by Frederick J. Drake & Co. Leather; 4½ x 7 inches; 265 pages; illustrated. Price $2.00.

This volume is intended as a hand-book of practical information for the users of electric light, architects, contractors and electricians. Only as much of the theory is given as is needed for a comprehension of the underlying principles. Emphasis is placed upon the practical points which must be considered in the laying out of illumination.

Farm Gas Engines. By H. R. Brate. Published by The Gas Engine Publishing Co., Cincinnati, Ohio. Cloth; 5 x 7 inches; 190 pages; illustrated. Price $1.00.

This is a practical treatise on the action of the parts necessary to the successful running of a gas engine and is intended for the non-technical man. Chapters are given on carburation, compression, ignition, lubrication and cooling, and descriptions are included of the different types of gas engines in common use.

Problems in Engineering. First series. Edited by Sydney G. Turner. Published by St. Bride's Press, Limited, London. Cloth; size 5 x 7½ inches; 186 pages; illustrated. Price $1.25.

This is a compilation of the questions and answers printed from the assistants' and students' section of the the "Surveyor and Municipal and County Engineer," of London. The present volume is published in response to requests from readers of this section. The series of questions and answers will be found of assistance in the solution of many knotty points which arise in the daily work of the municipal engineer, for the series cover practically every phase of the municipal engineers' work.

PUBLICATIONS RECEIVED.

American Waterworks Association. Proceedings for 1911 of the Thirty-first Annual Convention, held at Rochester, N.Y., June 9-10, 1911. Secretary-treasurer, John M. Diven, 47 State Street, Troy N.Y.

Association of Dominion Land Surveyors. The annual report, together with the papers read at the sixth annual meeting, held at Ottawa, on the 5th and 6th of March, 1912. Secretary-treasurer, E. M. Dennis, B.L.S., Ottawa.

Canal Statistics for the Season of Navigation, 1911. Issued by the Department of Railways and Canals. A. W. Campbell, Deputy Minister, Ottawa.

Memoir No. 28, Department of Mines, Geological Surveys Branch, The Geology of Steep Rock Lake, Ontario, by Andrew C. Lawson, and Notes on Fossils from Lime Stone at Steep Rock Lake, Ont., by Charles D. Walcott. R. W Brock, Director.

An Investigation of the Coals of Canada, With Reference to Their Economic Qualities, as Conducted in McGill University, Montreal, under the authority of the Dominion Government. In six volumes, Vol. 2 by J. B. Porter and R. J. Durley, issued by the Department of Mines, Mines Branch. Eugene Haanel, Director.

Commission of Conservation, Canada, 1912. The third annual report of the annual meeting held at Ottawa, January 16, 1912. James White, Secretary.

Illinois Water Supply Association. Proceedings of the fourth meeting held at the University of Illinois, March 5-6, 1912. Published by the society, Urbana-Champaign, Illinois.

Association for Standardizing Paving Specifications. The proceedings of the third meeting held at New Orleans, January 8-13, 1912. John B. Hittell, secretary-treasurer, 5917 Winthrop Avenue, Chicago.

The Test of Clay Refractories with Special Reference to Their Load-Carrying Capacity at Furnace Temperatures. By A. V. Bleininger and G. H. Brown, being No. 7 of the Technologic papers of the Bureau of Standards, Department of Commerce and Labor, U.S. S. W. Stratton, director, Washington.

The White River Development. A description of the construction of the Power Plant and system of Lakes at Puget Sound. Copyright, 1912, by Stone & Webster Engineering Corporation, Boston, Mass.

Electric Power from the Mississippi River. Being Bulletin No. 5, March, 1912, of the Mississippi River Power Co., Keokuk, Iowa.

Vitrified Brick Pavements. The National Paving Brick Manufacturing Association, Engineers' Building, Cleveland, Ohio, forward pamphlet illustrating the use of vitrified brick pavements for city streets and country highways.

CATALOGUES RECEIVED.

Circular 1155, entitled Series Arc Light Systems with Westinghouse-Cooper Hewitt Rectifiers, has just been issued by the Westinghouse Electric and Manufacturing Company. This publication deals very thoroughly with series arc light systems, describing in detail the rectifier apparatus, the arc lamps, and shows a number of views of detailed parts of the apparatus together with installations of same.

Descriptive Leaflet 2499, issued by the Westinghouse Electric and Manufacturing Company, describes their type Q M direct-current commutating pole motor for driving air compressors, pumps, and large blowers. These motors are particularly adapted for this class of service on account of the excellent commutation and the long life of the brushes and commutators. A special feature is the ventilation, as air can reach every part of the machine. The leaflet describes and illustrates the various component parts of the machine.

Descriptive Leaflet 2497, issued by the Westinghouse Electric and Manufacturing Company, covers the Westinghouse underwriter's motors, which have been completed and built in accordance with the specifications and requirements of the Chicago Local Board of Fire Underwriters. This motor has a blower attached to the outer end of the shaft for ventilation and will operate continuously at rated load and voltage with a temperature rise not exceeding 40 degrees centigrade. Its particular application is driving fire pumps and sprinkler systems in buildings.

Milling and Gear Cutters. Weir and Napier, engineers, 58 West Regent Street, Glasgow, forward catalogue illustrating milling and gear cutters, twist drills and splitting saws, in carbon or high speed steel. The firm desire agents in all the leading cities of Canada to represent their various lines.

Specialties for Marine Work. W. H. Allen, Son & Co., Limited, Bedford, England, forward catalogue illustrating different types of centrifugal pumps, electrical generating machinery, oil engines, steam turbines, etc. A. L. Melville, resident engineer, 69 Victoria Street, Toronto.

Industrial Railway System. The C. W. Hunt Company, West New Brighton, N.Y., forward folder illustrating different applications of the Hunt Industrial Railway System.

Concrete Machinery. The London Concrete Machinery Co., of London, Canada, forward catalogue illustrating different types of concrete mixers, concrete block machines and moulds, and the different concrete machinery manufactured by them.

Electrical Fixtures and Shades. A new supply catalogue issued by the Canadian General Electric Co., Limited, Toronto.

Crushing, Quarrying and Road Building Machinery. The Hamilton Machinery Co., Limited, Hamilton, Ont., the Canadian distributors for the American Road Machine Company, forward catalogues illustrating different types of crushing, road-building and quarrying machinery

Steel Valves. The Nelson Valve Company, Chestnut Hill, Philadelphia, Pa., forward catalogue illustrating various types of valves manufactured from bronze, iron and acid open-hearth steel.

Pumping Engines. The Standard Pump and Engine Co., Cleveland, Ohio, forward pamphlet entitled Standard Pumping Engines for Water Supply, consisting of different [illegible] of their apparatus.

Steam Turbines. The Kerr Turbine Company, of Wellsville, N.Y., forward pamphlet called The Economy Steam Turbine, [illegible] advantage of different types of steam turbines manufactured by them.

Railway Signals. The General Railway Signal Company, of Rochester, N.Y., forward [illegible] for their [illegible].

Engines. Ruston, Proctor & Co., Limited, Lincoln, England, forward [illegible] entitled The Products of Ruston, Proctor & Co., Engineers, Lincoln, England, which illustrates the different engines, suction gas plant, gas engines, road rollers, centrifugal pumps, etc., manufactured by them.

Conveying Machinery. The Jeffrey Manufacturing Company, Columbus, Ohio, forward their new general catalogue No. 82, illustrating Jeffrey elevating conveying power transmission machinery and coal mine equipments. The Jeffrey Manufacturing Co., are placing this catalogue in the hands of their customers and intending purchasers.

Electric Locomotives. The Railway and Lighting Department of the Westinghouse Electric Manufacturing Company, East Pittsburg, Pa., forward pamphlet describing the Baldwin Westinghouse Electric locomotive.

* * *

MACKENZIE-MANN GET DOMINION POWER COMPANY.

The Mackenzie-Mann interests are negotiating an important transaction by which they will obtain control of the Dominion Power and Transmission Company, the holding corporation of twelve electrical, generating, transmission, and consuming companies. The official ratification of the deal has yet to be made.

The companies controlled either directly or indirectly by the Dominion Power & Transmission Company are as follows:—The Hamilton Radial Electric Railway Company. The Hamilton Street Railway Company. The Hamilton and Dundas Street Railway Company. The Dundas Electric Company. The Hamilton Electric Light and Power Company. The Lincoln Electric Light and Power Company. The Brantford and Hamilton Electric Company, the Western Counties Electric Company, with its subsidiary corporation. The Brantford Electric and Operating Company. The Hamilton Terminal Company. The Welland Electrical Company. The Hamilton, Grimsby and Beamsville Electric Railway Company.

The authorized capital of the Dominion Power and Transmission Company, with head office at Hamilton, is $50,000,000. Of the preference stock, which is entitled to 7 per cent., $3,673,100 was subscribed and paid-up at the date of the latest annual report of the company, December 31st, 1911. Of the limited preference stock, (which has preference as to dividends over common of 10 per cent. in dividend in all of which 1½ per cent. has been paid), $5,100,000 has been subscribed and paid-up. Of the common stock, $2,622,500 has been subscribed and paid-up. The authorized bond issue is $25,000,000, of which $3,012,000 are outstanding. Bonds of subsidiary companies, amounting to $3,855,000, are outstanding.

The following are figures from the latest annual statement of the company:—

Gross earnings	$ 2,251,247.47
Interest	1,635.04
	$ 2,252,883.01
Operating expenses	$ 1,232,239.49
	$ 1,020,643.07
Bond interest	$ 335,758.42
	$ 684,884.65
The liabilities total	$20,045,040.98

Assets.

Property account	$19,[illegible]
Accounts receivable	[illegible]
Stores on hand	[illegible]
Trustees of bonds	50,018.25
	$20,045,040.98.

Profit and Loss Account.

Balance from 1910	$ 1,010,[illegible]89.63
Surplus earnings, 1911	684,884.65
Adjustments	18,882.93
Transferred to replacements	12,821.85
Transferred to reserve account	550,000.00
Dividend declared	5[illegible].21
Balance	7[illegible]4,[illegible].29
	$1,704,574.28

The incorporation of the Dominion Power and Transmission Company, Limited, was the result of necessary increase in the financial capacity of the Hamilton Cataract Power, Light and Traction Company, Limited, which became inadequate to meet the expansion of that company's business and the probable extension of its field of operation, and this company's charter from the Dominion of Canada was framed with a view to the acquisition by this company of the control, and practically the taking over of the business of the Hamilton Cataract Power, Light and Traction Company, Limited. In view of the fact that four-fifths of the stock of the Hamilton Cataract Power, Light and Traction Company, Limited, has been acquired by this company it may be regarded as a successor to that company and its business, but on a larger scale. The mileage of the company consists of 22 miles of double track in Hamilton and 23 miles of interurban lines, including an extension to Brantford over a private right-of-way.

Large shareholders have been requested to sign the agreement for the sale, and it is understood that all the stockholders are to receive $125 a share for their preference stock, $110 for their second preference, and $100 for their common stock. Stockholders seem to be satisfied with the terms.

The directors and officers of the company are as follows:—J. R. Moodie, president, Hamilton; James Dixon, vice-president, Hamilton; J. W. Sutherland, Hamilton; John Knox, Hamilton; Wm. C. Hawkins, Hamilton; Lloyd Harris, Brantford; Wm. Southam, Hamilton; Sir John M. Gibson, Toronto; secretary and general manager, Wm. C. Hawkins. The present directors will probably remain in charge until the annual meeting next February.

RAILWAY SIGNALLING EXPERIMENTS.

Interesting experiments have recently been made near Birmingham, England, with a remarkable invention designed by the inventor, Mr. H. von Kramer, with the object of preventing train collisions. The inventor's method is to have earth-buried wires laid alongside and parallel with each line of permanent way, which will communicate with the signal boxes all along the line. The guard's coach on the train is fitted with a coil framework whence electricity emanates, connecting with the buried wire. The signal is picked up from either the wire of the train by a "detector," and automatically magnified, so that it is capable of operating a bell, hooter, or even a brake.

In the guard's van are several electric "solenoids," erected on a marble slab, which are entirely automatic. When the detector operates, one of these rings a hooter, while another is used for pulling a lever in the van which puts on the brakes and stops the train. On the other hand, the train can signal from station to station, sending out a current which operates alarm bell and lamps.

If the signalman forgets to pull back a lever after a train has passed from one block section into another, this omission is automatically rectified by the current. If the train over-runs a signal at danger it will be automatically stopped, and will not be able to proceed until a seal has been broken in the signal box, where the incident is recorded. This automatic signal will not be blindly relied upon by the engine-driver and signalman, but rather increase their alertness, as they are certain of having their mistakes recorded without the question of doubt. There is a recording instrument in each box which, when straight, indicates that all is right, but if any trouble occurs it goes up at the exact moment of the incident, and remains in a position of danger.

An outstanding feature of the invention is the extreme delicacy of the detector, which can be tuned to any pitch and only respond to a similarly tuned instrument. For instance, one tuned to 100 frequencies (vibrations) per second would not respond to others of even 95 or 105 frequencies. Moreover, the detector is tunable to such an extent that the signalman can distinguish between goods, slow passenger, and fast trains.

It is impossible for two trains to collide in the same section. If one gets in legitimately it is all right, but if a second runs over the block both trains are automatically stopped.

The experiments are being carried on over a ten-mile stretch of the Stratford and Midland Junction railway between Stratford and Kineton, and so far have proved a striking success.

◆

PERSONALS.

MR. ADAM P. LINTON, of Regina, has been appointed assistant chief engineer for the Province of Saskatchewan.

MR. E. W. MURRAY, of Regina, has been appointed district surveyor and engineer for the Province of Saskatchewan.

MR. L. G. COLEMAN has been appointed superintendent of the Ottawa division of the Grand Trunk Railway, with office at Ottawa, Ont.

MR. H. G. PHILLIPS, of Regina, has resigned his position as district surveyor and engineer of Saskatchewan to engage in private practice.

MR. M. K. ALLAN has been appointed city engineer of Regina, to succeed L. A. Thornton, who was recently appointed city commissioner.

JAMES IRWIN, of Montreal, has been appointed to succeed G. G. Hare, civil engineer of the Kingston & Pembroke Railway Company, who has been transferred to the Dominion Atlantic Railway.

HON. FRANK COCHRANE has been appointed representative of the Federal Government to represent that body at the International Road Congress to be held in London, England next June.

MR. W. REES JEFFREYS, Honorary Secretary of the International Road Congress, is at present in Toronto arranging details of the meeting of that body to be held in London during June, 1913.

MR. R. O. WYNNE-ROBERTS has been asked by the Government of Saskatchewan to report on the lignite deposits of the province with reference to the possibilities for use as fuel, and for the development of cheap power.

MR. H. L. DRAYTON, K.C., has been appointed Chief Commissioner of the Dominion Railway Board to fill the vacancy caused by the death of Judge Mabee. Mr. Drayton's present position is Corporation Counsel for the city of Toronto.

◆

OBITUARY.

We regret to announce the death of Mr. Cecil B. Smith, senior member of the firm of Smith, Kerry & Chase, consulting engineers.

MEETINGS.

The members of the Ontario Motor League held a dinner in honor of Mr. W. Rees Jeffreys, of the Road Board of Great Britain in Toronto on the evening of June 26th last. Mr. Jeffreys explained the workings of the Road Board with which he is connected, and at the conclusion brief addresses were made by Messrs. W. A. McLean, highways engineer of Province of Ontario; Dr. P. E. Doolittle; Willis Chipman, president of the Engineers' Club ,and Dr. John Galbraith, dean of the faculty of engineering, University of Toronto. Among those present were Messrs R. P. Fairbairn, Deputy Minister of Public Works, Ontario; A. S. Forster, Reeve of Oakville; W. G. Trethewey, of the York Highway Board, and A. M. Rankin, M.P.P., Collins Bay.

COMING MEETINGS.

THE WESTERN CANADA IRRIGATION ASSOCIATION.—Sixth Annual Convention at Kelowna, Okanagan Valley, B.C. August 13, 14, 15 and 16, 1912. Secretary, Normon S. Rankin, P.O. Box 1317, Calgary, Alta.

THE UNION OF CANADIAN MUNICIPALITIES.—August 27, 28 and 29. Meeting at City Hall, Windsor, Ont. Hon. Secretary-Treasurer, W. D. Lighthall, K.C.

CANADIAN FORESTRY ASSOCIATION.—Convention will be held in Victoria, B.C., Sept. 4th-6th. Secy., James Lawler, Canadian Building, Ottawa.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Second Annual Meeting to be held in Toronto, Sept. 16, 17 and 18.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Annual Assembly will be held at Ottawa, in the Public Library, on 7th October, 1912. Hon. Sec'y, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE. Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the [illegible]

VANCOUVER BRANCH Chairman, C. E. Cartwright; Secretary, W. Alan, Kennedy; Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; [illegible]

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-jack. Meets every first and third Friday of each month, October to April, in [illegible]

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION.—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—[illegible] Head, Sask. [illegible] Hingley, [illegible]

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. [illegible]

THE UNION OF CANADIAN MUNICIPALITIES.—President, W. Sanford [illegible] Secretary-Treasurer, W. D. Lighthall, K.C., [illegible]

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. [illegible] Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor [illegible] W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor [illegible] Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

[illegible] MUNICIPALITIES.—President, Mayor Mitchell, [illegible], Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, [illegible] Reeve Cardale, Oak Lake, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont ; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President Arthur Hewit, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President, J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Jas. Anderson, Gen. Mgr., Sandwich, Windsor and Amherst Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman; Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President; Hon. W. R. Ross, Minister of Lands, B.C. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phœnix Block, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only unless otherwise noted at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close		Noted in issue of
7-3	—Storm Drain, Orillia, Ont. ....(P. & S.)	6-20
7-1	—Boilers, 300-h.p., Verdun, Que. ....(S.)	6-20
7-10	Supply of electrical machinery and sewage disposal works, Battleford, Sask. ....(P. & S.)	6-27
7-20	—Concrete Arch, Stratford, Ont. ....(P. & S.)	7-4

(Battleford plans and specifications are also on file at The Canadian Engineer Offices, Montreal and Winnipeg.)

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

TENDERS.

Brockville, Ont.—Tenders for paving and laying storm drains, etc., on King Street, will be received until July 15th, 1912. Full particulars can be obtained from G. H. Bryson, Town Engineer, Brockville. (See advt. in The Canadian Engineer.)

Buchanan, Sask.—Tenders for the building of a two-story solid brick school house, to be built in accordance with plans and specifications prepared by Messrs. Storey & Van Egmond, Regina, will be received until July 15th, 1912, at the office of Albert Hermanson, secretary-treasurer, Buchanan.

Cumberland, B.C.—Tenders for the construction of cement sidewalks will be received until July 8th, plans and specifications of which may be seen at the office of the City Clerk, Cumberland, B.C. S. McKinnon, City Clerk, City Hall.

Duck Lake, Sask.—Tenders will be received until noon of July 15th, for all work in the erection and completion of a Town Hall in the Town of Duck Lake, Sask. Plans and specifications at the Kings Hotel, Duck Lake. Wm. Fawcett, Mayor; F. Hopwood, Secretary-Treasurer.

Edmonton, Alta.—Tenders for the various trades wanted for the erection of the Strathcona Hospital, Alberta Grounds, Edmonton South, will be received until July 6th, 1912, by Robert Farquharson, Secretary Hospital Board, Bank of Commerce Building, Whyte Avenue. Wilson and Herrald, Architects and Structural Engineers, South Edmonton.

Edmonton, Alta.—Tenders will be received by the City Commissioners up to 31st July, 1912, for steel pipes and specials, and to noon of August 9th, 1912, for gasholder and tank. Specifications, etc., may be obtained at the office of the City Gas Engineer, 143 Elizabeth Street, Edmonton.

Estevan, Sask.—Tenders will be received until July 16th, 1912, for the construction of the following works:—

Contract "M"—Waterworks force main.
" "P"—Waterworks pumphouse.
" "D"—Water pipes.
" "G"—Pumping machinery.
" "I"—Pump well.
" "O"—Outfall sewer.
" "X"—Sewage disposal works.

Plans and specifications may be seen at Estevan, or at the engineers' offices. L. A. Duncan, Esq., secretary-treasurer; Chipman & Power, engineers, Toronto and Winnipeg.

Estevan, Sask.—Tenders will be received by H. N. Scott, secretary-treasurer, High School Board, Estevan, until noon of July 10th, 1912, for the erection of a Collegiate Institute building. Plans and specifications may be seen at the office of Storey & Van Egmond, Architects, Regina, Sask.

Guelph, Ont.—Tenders will be received by T. J. Moore, City Clerk, up to July 13th, for the construction of approximately 10,500 square yards of pavements. Particulars, etc., at the office of M. Ferguson, City Engineer. (See advt. in The Canadian Engineer.)

Kingston, Ont.—Tenders for the construction of 7,200 square yards of asphalt block or vitrified brick pavements and 3,000 lineal feet of concrete curb, will be received at the office of City Engineer, R. J. McClelland, until July 16th, 1912. Plans and specifications at the office of the Engineer. (See advt. in The Canadian Engineer).

Lethbridge, Alta.—Tenders will be received at the office of the Secretary-Treasurer up to noon of July 15th, 1912, for a freight elevator. Specifications can be seen at the office of the General Superintendent, City Hall. A. Reid, General Superintendent, Geo. W. Robinson, Secretary-Treasurer.

Moose Jaw, Sask.—Tenders for the supply and delivery, f.o.b. Moose Jaw, of one 500 k.w. steam driven generating set, will be received up to noon of August 1st, 1912. Specifications, etc., may be obtained upon application to J. D. Peters, Electrical Superintendent, Moose Jaw, or the Commercial Intelligence Branch, Board of Trade, 73 Basinghall Street, London, England. (See advt. in The Canadian Engineer.)

Ottawa, Ont.—The Department of Public Works, Ottawa, is open to receive tenders until July 11th, 1912, for interior fittings, post office, Fairville, N.B. Plans, etc., to be seen on application to Mr. G. E. Bettinson, Clerk of Works, Fairville, N.B.; Mr. D. H. Waterbury, Clerk of Works, St. John, N.B.; and at the Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders will be received until July 19th, 1912, for the following works at Point Tupper:—A ten-stall engine house and annex; a brick chimney with concrete foundation; a concrete cinder pit; moving the existing stores and office building, and providing new foundation. Plans and specifications may be seen at the office of the Secretary of the Department of Railways and Canals, Ottawa; at the Station Master's Office, Point Tupper, N.S., and at the Chief Engineer's Office, Moncton, N.B. A. W. Campbell, Chairman, Government Railways Managing Board, Ottawa.

Ottawa, Ont.—Tenders for the construction of an extension to breakwater at Reed's Point, Lorneville, St. John County, N.B., will be received at the office of the Secretary, Department of Public Works, Ottawa, until July 24th, 1912. Plans, etc., at the Department, and at the offices of E. T. P. Shewen, Esq., District Engineer, St. John, N.B.; Geoffrey Stead, Esq., District Engineer, Chatham, N.B., and on application to the Postmaster at Lorneville, N.B.

Ottawa, Ont.—Tenders will be received until July 8th, 1912, for Port Colborne entrance improvements. Plans, etc., at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Superintending Engineer of the Welland Canal, St. Catharines, Ont. L. K Jones, Secretary, Department of Railways and Canals, Ottawa.

Ottawa, Ont.—Tenders for the construction of a sea wall at Windsor, Hants County, N.S., will be received by the Secretary, Department of Public Works, Ottawa, until July [illegible], 1912. Plans, etc., can be seen at that Department, and at the offices of H. A. Russell, Esq., District Engineer, Halifax, [illegible] District Engineer, Antigonish, N.S., and on application to the Postmaster at Windsor, N.S.

Ottawa, Ont.—Tenders will be received until July 16th, [illegible] at Richmond, N.S. Plans, etc., at the office of the Secretary of the Department of Railways and Canals, Ottawa, the Station Master's Office at Richmond, N.S., and at the Chief Engineer's Office, Moncton, N.B.

Regina, Sask.—[illegible] Acting Deputy [illegible] Regina.

Regina, Sask.—Tenders will be received until July 12th, 1912, for the undermentioned works:—

Group 1:—

(a) Two reinforced concrete bridge abutments for a bridge over [illegible] River, near [illegible], Sask.

(b) Two reinforced concrete bridge abutments for a bridge over [illegible] River north of [illegible].

(c) Two reinforced concrete bridge abutments for a bridge over Whitesand River, near Gorlitz Siding, G.T.R. Railway.

(d) Two reinforced concrete bridge abutments for a bridge over Whitesand River, near Yorkton.

(e) Two reinforced concrete bridge abutments for a bridge over Quill Creek, south of Wadena.

Group 2:—

(a) Two reinforced concrete bridge abutments for a bridge over Wood River at Gravelburg.

(b) Two reinforced concrete bridge abutments for a bridge south of Gravelburg.

(c) Two reinforced concrete bridge abutments for a bridge north of Gravelburg.

Group 3:—

(a) Two reinforced concrete bridge abutments for a bridge over Moose Mountain Creek, north of Oxbow.

(b) A reinforced concrete bridge at Brooking.

Plans, specifications and full information may be obtained on application to A. J. McPherson, Chairman, Highway Commission, Regina, Sask.

Regina, Sask.—Tenders for the construction of earth grade across Lake Chaplin, providing the necessary stone for and rip-rapping embankment, will be received until July 13th, 1912. Full particulars may be had on application to A. J. McPherson, Chairman, Highway Commission Board, Regina.

Regina Sask.—Tenders will be received until noon of July 20th, 1912, for the erection and completion of an addition to the Regina Collegiate Institute, tenders to be addressed to the Secretary-Treasurer, Regina Collegiate Institute Board, Regina. Plans and specifications may be secured at the office of Messrs. Storey and Van Egmond, Architects, Credit Foncier Building, Regina, and at the Builders' Exchange, Winnipeg.

St. Charles, Man.—Tenders to furnish all material and to erect a fire hall and police station on Berry St., in D.G.S., 34-5, St. James, will be received until July 10th. Plans and specifications at the office of Frank Ness, secretary-treasurer, Rural Municipality of Assiniboia, Kirkfield Park P.O., Man., St. Charles.

St. John, N.B.—Tenders are invited by the city of St. John for the following work to be received by the Common Clerk, Room No. 3, City Hall, up to noon of July 8th:—

Bituminous macadam pavement in King Street, and granite block pavement in track allowance.

Sheet asphalt pavement in Charlotte Street, and vitrified brick pavement in track allowance.

Excavation, backfilling and cartage for main sewer renewal in Main Street, Paradise Row and Hazen Alley.

Replanking of sidewalk North Rodney wharf. Plans and specifications to be seen in the office of the City Engineer, Room No. 5, City Hall.

Stratford, Ont.—Tenders for the construction of approximately 6,488 lineal feet of concrete arch, covering Romeo Creek, will be received by A. B. Manson, City Engineer, up to July 20th, 1912. Plans, etc., at the office of The Canadian Engineer, or at the office of the City Engineer, Stratford. (See advt. in The Canadian Engineer).

Toronto, Ont.—Tenders will be received until noon of July 15th, 1912, for the construction of a concrete sidewalk on Ravensden Avenue, Township of York. Plans, etc., at the office of Mr. Frank Barber, Township Engineer, 57 Adelaide Street East, Toronto. (See advt. in The Canadian Engineer.)

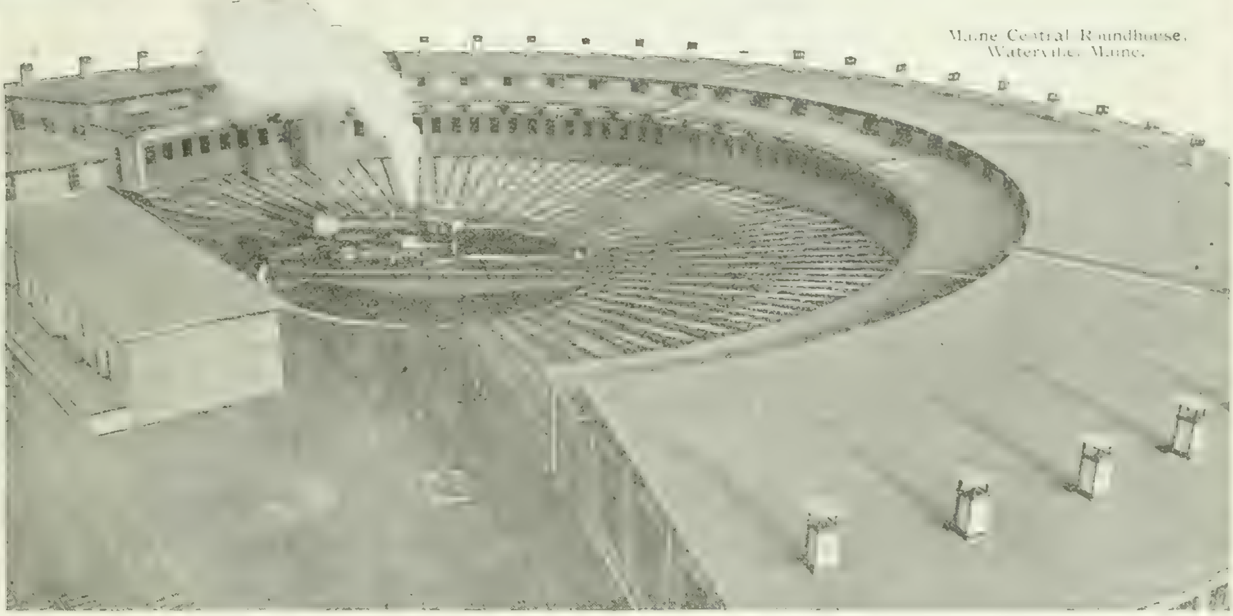
Vernon, B.C.—Tenders will be received by D. G. Tate, City Clerk, Vernon, until July 15th, 1912, for the supply of fuel oil for Diesel Type Oil Engine, for a period of one, three or five years. Messrs. Mather, Yuill and Company, Limited, Consulting Engineers, Vancouver B. C. (See advt. in The Canadian Engineer.)

Victoria, B.C.—Tenders will be received by W. Galt, Purchasing Agent, City Hall, Victoria, until July 8th, for [illegible] feet [illegible] No. [illegible] cable, [illegible] feet No. 16 duplex cable, [illegible] miles No. 12 W P B & S gauge steel wire.

Woodstock, Ont.—Tenders for wiring County Court House, Oxford County, will be received until July 8th, 1912, by N. F. [illegible], County Clerk, Woodstock. Plans and specifications at the Clerk's office.

Winnipeg, Man.—Tenders for the manufacture, delivery and erection in high pressure plant of alternators, switching apparatus and accessories, will be received until July 17th, 1912. Specifications, etc., may be had at the office of the City Light and Power Department, 54 King St. M. Peterson, Secretary, Board of Control Office, Winnipeg.

Barrett Specification Roofs



Maine Central Roundhouse,
Waterville, Maine.

THE RAILROAD TEST.

THE hardest kind of a building to roof successfully and economically is a railroad roundhouse.

Such a building is exposed to heat inside, condensed vapor from above and below, as well as acid fumes of coal smoke and the constant dropping of cinders and sparks on the surface. All this, in addition to the ordinary wear and tear of the weather.

Only one type of roofing can stand up under such conditions successfully and that is a Barrett Specification Roof.

Its low cost makes it attractive to begin with and the fact that there is no maintenance expense such as painting or coating, makes the net cost per year of service far below that shown by any other roof covering.

The reasons which make Barrett Specification Roofs particularly desirable for roundhouses make them even more desirable and economical when used on manufacturing plants, warehouses, apartments in fact, on all flat-roofed commercial structures.

Every architect, engineer and owner should have a copy of The Barrett Specification with tracings for use in future building plans and we are pleased to mail same free on request to our nearest office.

Special Note

We advise incorporating in plans the full wording of The Barrett Specification, in order to avoid any misunderstanding.

If any abbreviated form is desired, however, the following is suggested:

ROOFING—Shall be a Barrett Specification Roof laid as directed in printed Specification, revised August 15, 1911, using the materials specified, and subject to the inspection requirement.

THE PATERSON MANUFACTURING CO., LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER ST. JOHN, N.B. HALIFAX, N.S.

Winnipeg, Man.—Tenders for the supply of a quantity of water meters, will be received until noon of July 18th, 1912. Specifications, etc., at the office of the City Engineer. 223 James Avenue. M. Peterson, Secretary, Board of Control Office, Winnipeg.

Winnipeg, Man.—Tenders or supply of labor and materials required in the erection of a 42-foot steel span, concrete and foundation work for permanent approaches to Louise Bridge, will be received until July 11th, 1912. Plans, etc., at the office of the City Engineer, 223 James Avenue. M. Peterson, Secretary Board of Control Office, Winnipeg.

◆

CONTRACTS AWARDED.

Coleman, Alta.—The School Board have received the following contracts for the construction, painting and plumbing of the new addition to the Coleman School building:—

Construction—E. Disney, $4,950.

Plumbing—The H. G. Goodeve Co., $772.50.

Painting—D. Fraser, $773.50; E. Parrish, $750; R. Dunlop, $602.70; C. F. Higgins, $587.

The contracts were awarded to Messrs. Disney, Goodeve Company and Higgins.

Kamloops, B.C.—The contract for cluster lighting supplies was awarded to Messrs. Hutchinson Bros., Victoria, their tender being $52,000.

Tenders for retaining wall and fill on Nicola Street were opened, the only tender being that of the Graff Construction Company at $1,428. The contract was awarded that firm.

Lethbridge, Alta.—The Elose Paving Company, of Vancouver, was awarded a contract by the city council for paving 20,000 square yards of the streets of the city for the sum of $45,747.50 over the Bitulithic Company, whose tender was [illegible]

Township of London, Ont.—F. W. Farncomb, C.E., acting for the Township of London, has accepted the tender of Bayne and Ross, Embro, for concrete breakwater on the Medway River at $5.48 per cubic yard. Probable cost will be $4,300.

Montreal, Que.—Mr. D. Lorne McGibbon, president of the Consolidated Rubber Company, announces that their company will build a $1,000,000 tire factory, it is thought somewhere in Ontario.

Montreal, Que.—The Board of Control recommends the letting of the contract for the pumping required to divert the Elgin Basin sewer be awarded to the firm of J. T. Farmer at $14,160. The board set aside a tender for constructing a pump building.

Messrs. H. Birks & Sons' Building.—A contract has been let for the construction of an $87,000 ten-story reinforced concrete frame building for Messrs. Henry Birks & Sons. The Norton Griffiths Steel Construction Company has received the contract, the architects being Messrs. Somerville and Putnam.

New Westminster, B.C.—The contract for the construction of the new wharf for Mr. E. J. Fader and his associates has been awarded to Mr. W. A. Gilley, who will commence piling immediately. This wharf will be 600 feet long by 100 feet deep, and it is intended to be the strongest wharf in the city.

Niagara Falls, Ont.—The Cumberland Company of Oakville, have let the contract of building twelve miles of [illegible] Messrs. Lorenze, Murray & Spencer, have the contract.

New Westminster, B.C.—Contracts were let for the paving [illegible]

Regina, Sask.—The Commissioners brought down a [illegible] which was the

lowest figure quoted, and approximately $10,000 less than the highest tenderer's price. They are also recommending the council to purchase plain round rods to the value of $6,596.30 from the Provincial Steel Company, and to buy cement at $2.85 1-2 per barrel from the Canada Cement Company, the lowest tenderer on cement.

Tisdale, Sask.—The contract for the new $10,000 school has been let to the firm of Messrs. Dempsey and Hunter, contractors and builders of this town.

South Vancouver, B.C.—Contracts for the erection of eight-room additions to the Carleton Tecumseh and General Wolfe schools were let by the school board to Messrs. Snider & Brethour and Charles Harrison. Snider & Brethour will build the addition to the Carleton and Tecumseh schools for $32,448 each. Mr. Charles Harrison received the contract for the erection of the General Wolfe addition, his bid being $35,649. Tenders for the building of two two-room schools were opened. The contract for the erection of the school on Sixty-first Avenue was let to Mr. F. P. Rogers for $2,325, and the new Kerr road school will be built by Fletcher and Bonhon at $2,050. Twenty-one tenders were received.

◆

RAILWAYS—STEAM AND ELECTRIC.

Halifax, N.S.—The receipts of the Halifax Electric Tramway Company, Limited, for the week ending June 21st, 1912, were as follows:—

1912.	1911.	Increase.
$5,069.63	$4,759.59	$310.04

Montreal, Que.—It is announced that the North Railway Company of Canada who have the franchise for a projected line from Montreal to Nottawa on the James Bay have financed the project. The survey and location work is now being rushed, and construction will begin in the spring. Mr. F. H. Clergue is interested in the financial arrangements. Mr. E. A. Evans, C.E., of the Quebec Provincial Government has been over the line for the Government.

Saskatoon, Sask.—A by-law was passed to raise $500,000 for the construction of a street railway system in this city. Messrs. Stone and Webster, of Boston, are the constructing engineers and work is already under way.

◆

LIGHT, HEAT AND POWER.

Galt, Ont.—Three by-laws were passed on June 27th, one for $45,000 for the completion of the hydro-electric lighting system and extension of private services, one for the renewal of the Galt, Preston and Hespeler Railway franchise for ten years, and one for $13,500 for permanent civic improvements and road work.

Humboldt, Sask.—The council have decided to submit by-law to the people to raise $30,000 for an electric light system for the town.

Moose Jaw, Sask.—The municipal electrician has submitted a report to the council dealing with the new power house. In this he advocates the change to three phase current, the construction of the building in fire proof materials with steel frame, one additional generator over the number previously employed. The estimated cost of this building is $68,000.

Ottawa, Ont.—A new plant recently installed for the Great North Western Telegraph Company consists of sixteen machines, eight alternating two-phase 60 cycles, 220 volt motors, direct connected to eight generators, with ranges from 25 to 300 volts, the machines being mounted upon a concrete pier, which also supports the slate controlling switch panels, located immediately above. Under the new system, electrical currents of various voltages are placed upon the wires direct from the generators which are capable of being regulated over a wide range. This plant gives the local office of the Great North Western one of the most modern and up to date equipments of any telegraph office in Canada.

Province of Ontario.—The Hydro-Electric Commissioners are planning to send two electric thrashing outfits throughout the province during the coming harvest season and demonstrate to the farmers means whereby this source of power may be used on their farms.

Toronto Townships, Ont.—A meeting to discuss the securing of power from the Hydro-Electric Commissioners was held at Port Credit.

48 in. CONTINUOUS STAVE LINE.

Manufacturer of
Galvanized Wire Machine Banded

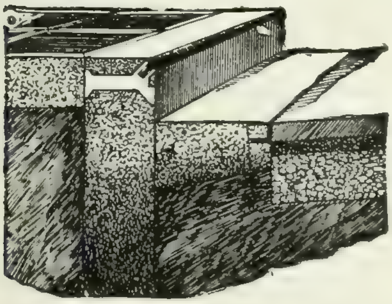
WAINWRIGHT GALVANIZED STEEL CORNER BAR

FOR PROTECTING EDGES OF CONCRETE CURBS, STEPS, COLUMNS, ETC.

WAINWRIGHT PATENTS
March 9, 1897
November 22, 1898
May 5, 1903
March 26, 1907
August 29 1907
August 2, 1910
Canadian Patent 92208

IT HAS A RECORD OF FOURTEEN YEARS' USE WITHOUT A FAILURE.

THIS BAR IS SELF-ANCHORING, THE DOVETAILED WEB HOLDING IT FIRMLY IN PLACE EVERY INCH OF ITS LENGTH, PRESENTING A RESISTING DEPTH OF TWO INCHES OF SOLID STEEL, AT EVERY POSSIBLE POINT OF IMPACT.

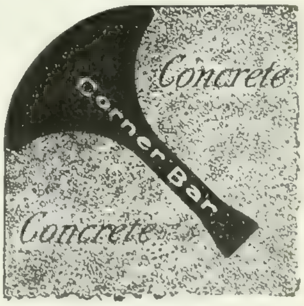


This bar has been in public use for more than fourteen years as the main feature of the

WAINWRIGHT

STEEL-BOUND CONCRETE CURB

ABSOLUTELY NON-BREAKABLE
CHEAPER THAN GRANITE



GALVANIZED STEEL CORNER BAR prevents Chipping or Breaking on Edges
MECHANICALLY PERFECT AND UNEQUALLED FOR CURVED CORNERS.

OVER FOUR MILLION FEET IN USE IN MORE THAN FOUR HUNDRED CITIES IN THE UNITED STATES.

THIS CURB WILL STAND HARDER USE AND LAST TEN TIMES AS LONG AS PLAIN CONCRETE CURBING

CONTRACTORS can make money by laying this curb. CITY ENGINEERS can save money by specifying it.
ARCHITECTS are invited to read pages 238 and 239 "Sweet's Index."

METAL PARTS FOR SALE. **Send for Copyrighted Booklet No. 14.**

STEEL PROTECTED CONCRETE CO., Real Estate Trust Bldg. **Philadelphia, Pa.**

GARBAGE, SEWAGE AND WATER.

Bolton, Ont.—F. H. Farncomb, C.E., London, Ontario, has [illegible] a report to the town of Bolton, for proposed waterworks. The report covers alternative schemes for spring water, deep well and filtration. The latter is recommended. A by-law will be submitted. Estimated cost $25,000. It is expected that the Canadian Pacific Railway will become a large consumer.

Melfort, Sask.—The ratepayers of Melfort have passed three debenture by-laws, totalling $120,000, for waterworks, sewers, sewerage, trunk sewers, and electric plant system. Tenders have been accepted and work will be commenced immediately.

Regina, Sask.—Three tenders have been received for the construction of water main extensions in the city and the commissioners are recommending the council to award the contract to John Brodt at a total cost of $13,761, as follows: 19,000 lineal feet of 6-inch mains at 56 cents per foot; 3,000 lineal feet of 8-inch mains at 60 cents; 350 lineal feet of 18-inch mains at 74 cents per foot.

Regina, Sask.—The contracts for the cast-iron pipe and specials for the construction of water main extensions are to be awarded to the National Iron Works and the Canada Iron Corporation. The former is to deliver 200 tons of pipe and 8 tons of specials at a cost of $8,854 and the latter, 146 tons of pipe and 5 tons of specials at a cost of $6,472.

Regina, Sask.—Orders have been placed by the commissioners for the purchase of an engine costing $3,565 from Crosley and Company of London, England and a pump costing $740 from the Canada Foundry Company. This will be a duplicate unit to the one already installed at the pump well house and will be capable of pumping four million gallons of water a day.

Toronto, Ont.—The municipal council has authorized the establishment of two sewage chlorination plants, at a cost of $12,[illegible].

Welland, Ont.—The Medical Health Officer will advise the municipal council to install a chlorinating plant for use in connection with the supply of water. Dr. Howell is the holder of this office.

Welland, Ont.—Welland will chlorinate its water supply from the Welland Canal, in order to prevent an outbreak of typhoid. It is thought the town will have to establish a sewage disposal plant.

◆

BUILDINGS AND INDUSTRIAL WORKS.

Blairmore, Alta.—The Keystone Portland Cement Company intend constructing a cement plant here to cost $400,000, and to have a capacity of 1,500 barrels per day. The plant will consist of twelve buildings, the largest of which will be a stock house 25 x 60 feet. The power house will be 140 x 60. The syndicate financing the construction of the Blairmore plant has announced that a 2,500 barrel establishment will be erected on the Pacific Coast.

Calgary, Alta.—Steps will be taken shortly towards the erection of a Labor Temple in Calgary.

Calgary, Alta.—The Walker-Fyshe Company have the [illegible]

Carmangay, Alta.—The farmers here propose building a [illegible] elevator.

Estevan, Sask.—[illegible]

Halifax, N.S.—Plans and specifications are being prepared for the erection of a Masonic Temple. Estimated cost, [illegible].

Hamilton, Ont.—[illegible]

Montreal, Que.—[illegible] Arena. If the present plans are carried out, work will be commenced toward the latter part of July, and be completed by November next.

Montreal, P.Q.—Mr. L. Cohen, president of the Baron de Heisch Institute, has had plans prepared for a 10-story building to be erected at the corner of Craig and St. George Street.

Montreal, Que.—The wardens of St. Joseph of Bordeau have obtained a permit to construct a Catholic church on Viel Street valued at $120,000.

Prince Albert, Sask.—Large building operations are being carried on this month, the value of permits from June 6th to June 21st totalling the sum of $200,000.

Toronto, Ont.—The Dominion Bank have decided to put up a new building at the corner of King and Yonge Streets. The plans and specifications are well under way.

Victoria, B.C.—Messrs. Dunford and Son will erect an apartment house on Government and Simcoe Streets, at a cost of $45,000. Designs prepared by Captain H. J. R. Cullin. Material will be brick, concrete and wood.

Welland, Ont.—Building permits, 14 issued for June, value $19,313. No records for June, 1911. Total value of permits 1st six months of 1912 amount to $124,186.

Winnipeg, Man.—Mr. J. A. Glasford, manager of terminals, has intimated that there will be considerable work done around the Union Station with a view of beautifying the premises.

◆

BRIDGES, ROADS AND PAVEMENTS.

East Toronto, Ont.—A deputation waited upon the Works Commissioner requesting that a hill on Du Vernet Avenue be cut down and the earth used to fill a nearby hollow.

Toronto, Ont.—The Commissioners of Works has recommended the construction of a 24-foot medium asphalt pavement on Ossington Avenue from Bloor Street to the Canadian Pacific Railway tracks. Of the total cost of $24,308 the property benefited will bear $18,830 and the city $5,478.

◆

FIRES.

Chicoutimi, P.Q.—A great amount of damage was caused to this town by fire on June 25th last.

West Lahave, N.S.—The woodworking plant and sawmills of Boehmr Brothers, were completely destroyed by fire with a loss of $60,000.

Sarnia, Ont.—The new plant of the Sarnia Gas & Electric Light Company was destroyed by fire on the morning of June 27th last. The loss is estimated at $300,000.

Ottawa, Ont.—The large gasoline truck belonging to the Ottawa Electric Light Company, valued at $900, was almost totally destroyed by fire.

◆

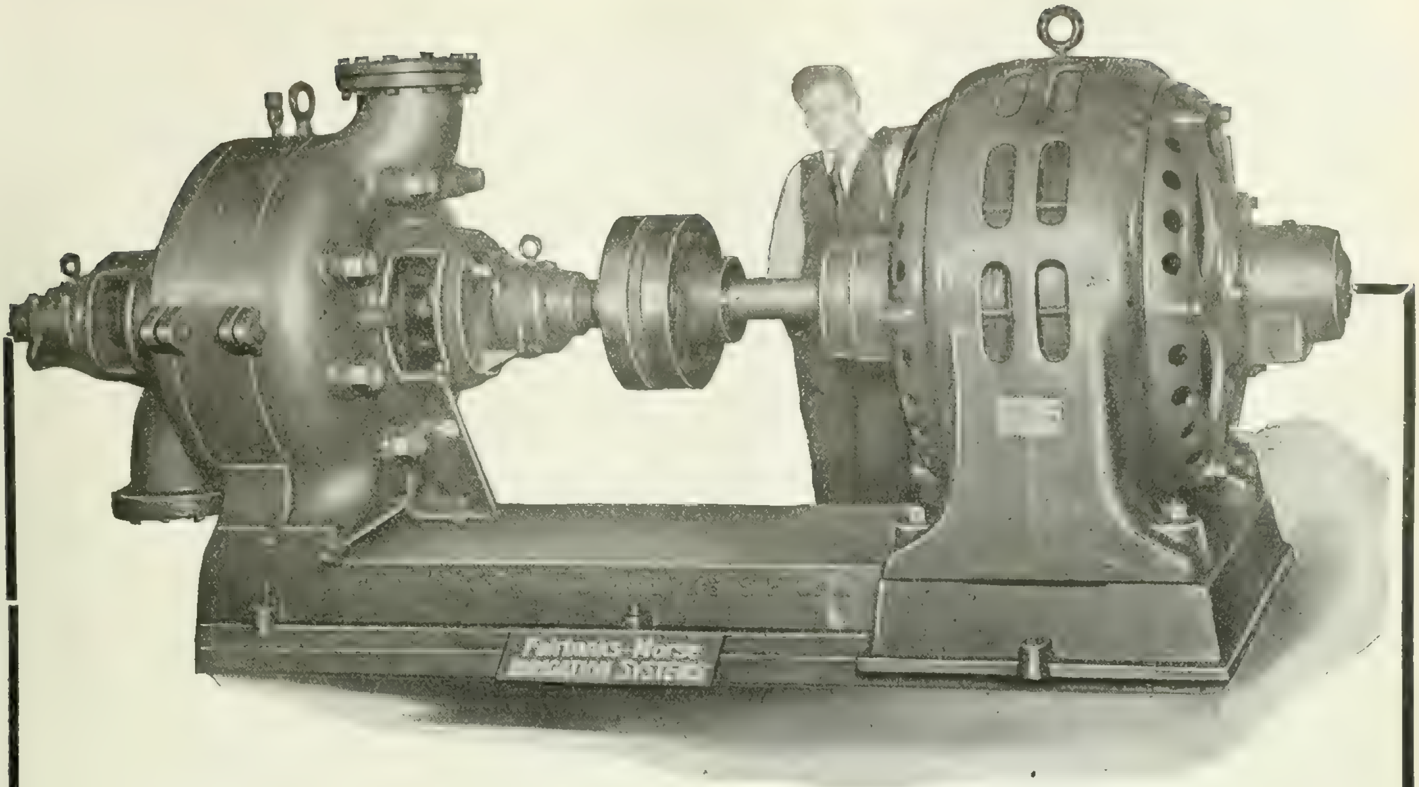
CURRENT NEWS.

St. Catharines, Ont.—The Department of Militia are about to construct a set of rifle ranges near this city.

Tofield, Alta.—The officials of the Grand Trunk Railway report a find of natural gas at this point in large quantities. This place is about forty-one miles from Edmonton and is also the scene of a recent coal discovery.

Toronto, Ont.—Classes in sanitary work for the instruction of the seven physicans appointed by the government as district medical officers of health will open on the first of August. Lectures will be given by Dr. J. W. S. McCullough, chief medical officer of health of the province; Dr. John Amyot, head of the provincial laboratories, and Dr. R. W. Bell, provincial inspector of the Board of Health.

Toronto Island.—A sea wall is to be erected at the Island to preserve the western end of the new athletic field, which has of late been affected by the action of the waves. The work will be done by the Harbor Commission. Engineer F. L. [illegible], has submitted two plans of the proposed wall to Parks Commissioner Chambers for approval.



The Largest Direct Connected Centrifugal Pumping Unit in British Columbia.

The Vancouver Power Company have recently installed at their works at Coquitlam Dam, B.C., the largest direct connected centrifugal pumping unit in British Columbia. This outfit is to operate in parallel with a number of other pumps that are to furnish water under pressure for sluicing into place the material for their new dam.

This pump is a 10-inch, class "F," two-stage centrifugal, with bronze inpellers and renewable bronze diffusion vanes. It has a normal capacity of 1833 imperial gallons per minute when operating at 1160 r.p.m. against a total head of 355 feet or an equivalent pressure of 154 lbs. per square inch. It is mounted on a common sub-base with a 300 h.p. type "B," Fairbanks-Morse squirrel cage, induction motor, 2200 volts, 60-cycle, 3-phase, 1160 r.p.m. at full load, being direct connected thereto by means of a flexible leather link coupling.

The motor possesses a feature in rotor construction that is unique. The end rings are welded on to the rotor bars by a new process, making a perfect joint, free from the troubles common to the purely mechanical or riveted joint, such as oxidation, working loose, and solder-throwing. This improvement marks a long step forward in the elimination of rotor trouble.

Our Vancouver Branch supplied and assembled this complete pumping unit. We are in a position to quote on the necessary equipment for any pumping requirements on receipt of specifications.

COPIES OF ENGINEER WANTED.

Copies of The Canadian Engineer of the issue of June 20th, 1912, are desired. The usual extension of the sender's subscription will apply in this case.

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending June 17th, 1912.

An English firm manufacturing a patent improved safety hook for use in mines, desire to hear from mining engineers in Canada who may be interested.

A London firm interested in a new process for utilizing waste vegetable matter, such as twigs and needles of pine trees, bark from pulp factories, sawdust, hedge cuttings, etc., make inquiry respecting sources of supply in Canada.

A London firm make enquiry for the names of Canadian importers of electrical meters, motors, fans, measuring instruments, and metallic filament lamps.

A London firm handling iron, steel, tin-plates, metals and hardware, desire to enter the Canadian market.

An Austrian correspondent makes inquiry for the names of Canadian exporters of linseed.

From the branch for City Trade Inquiries, 73 Basinghall Street, E.C.

A Scottish company manufacturing paper machine wires are prepared to offer their agency to some resident Canadian agency firm who are already calling on paper mills in connection with other supplies.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

[illegible] June [illegible]—Approving revised location of C.N.O. [illegible] Dist. of Nipissing, mileage [illegible] Badgerow and Gibbons, [illegible]

[illegible] C.P.R. to construct a [illegible] farm crossing [illegible]

[illegible] C.P.R. [illegible] track for inter-[illegible] by Order No. [illegible], January [illegible]

[illegible] time for installation [illegible] Order [illegible], May 3rd, 1912. [illegible]

[illegible] C.P.R. [illegible] at Meath, [illegible]

[illegible] by C.P.R. [illegible] Order No. [illegible], February [illegible]

[illegible] C.P.R. [illegible]

[illegible] Great [illegible]

[illegible]

[illegible] at [illegible]

[illegible] C.P.R. [illegible]

[illegible]

16819 June 19—Approving revised location of C.N.O. Ry. through unsurveyed territory in Dist. of Algoma, mileage 208.3 to 211.47 from Sudbury Junction.

16820—June 20—Authorizing G.T.R. to extend its passing track and to re-align its main line over County Line Road, Twp. of Brant, County of Bruce, Ontario.

16821—April 12—Relieving C.P.R. from erecting and maintaining fences on certain portions of its Fort William, Ignace, and Kenora Subdivisions.

16822—June 24 Authorizing G.T.P. Ry. to open for carriage of traffic between Hinton (mileage [illegible]), and Fitzhugh (mileage [illegible]), in Province of Alberta, speed limit of 20 miles per hour.

16823—June 20—Park Ave. Subway, Montreal, Que. Ordering that city of Montreal be subject to fine of $25 per day for every day after 24th June, 1912, that they are in default of commencing work required by Order [illegible], May 13, 1912, and $25 per day for every day after 15th Dec., 1912, that they are in default of completing work.

16824 June 20—Extending pending sanction of Governor-in-Council of agreements time for operation of Midland Ry. trains over C.N.R., Winnipeg, terminals. Order [illegible], dated May [illegible], 1912.

16825 June [illegible]—Extending until Oct. 1st, 1912, time for completion by C.N.R. of spur into H.B. Reserve, Edmonton.

16826—June 18—Authorizing C.P.R. to construct its Moose Jaw North-Westerly Branch across 34 highways in Saskatchewan.

16827—June 22—Authorizing C.P.R. to use and operate bridge 69.3 on its Boundary S.D.

16828—June 22—Approving revised location James Bay & Eastern Ry. in Twp. of Roberval, Ct. Lake St. John, Quebec.

16829—June [illegible]—Authorizing British Yukon Ry. Co. to open for carriage of traffic its branch line at mile post [illegible], to Pueblo Mine, 13 miles.

16830—June 21—Approving revised location of Edmonton, Dunvegan and B.C. Ry. Co., mile 3 to 14, Alberta.

16831 June 17 Dismissing application of Publishers' Press, Ltd., of Montreal, Que., re Bell Telephone service.

16832 June 20 Amending Order [illegible] of Sept. [illegible], 1911, by substituting plan dated Feb. 17, 1912, re Scarlett Road Subway, C.P.R., to be reimbursed, 20 per cent. from Rly. Grade Crossing Fund.

16833—June 24—Approving location of portion of C.P.R. Moose Jaw Southwesterly Branch at mileage 37.85 to 64.47, Sask., and authorizing crossing of 22 highways on same.

16834—June 21—Authorizing C.P.R. to construct four spurs across Symes and Gunns' Roads, Toronto, Ontario.

16835 June 24 Extending until 31st August, 1912, time for completion of C.P.R. spur into premises of Hanson & Van Winkle Co., Ltd., Toronto, Ont.

16836—June 24—Relieving C.P.R. from erecting and maintaining fences on its Lac Du Bonnet Subdivision.

16837—June 18—Re C.P.R. spur crossing G.T.R. and joining lines used in common by C.P.R. and G.T.R. near Clarence Square to take certain lands of city of Toronto, etc., in connection with enlargement of freight terminals, etc.

16838 June [illegible] Dispensing with services of night watchman at crossing by C.N.O. Ry. of C.P.R. near Ottawa, Ontario.

16839 June 21 Authorizing C.P.R. to construct extension to siding already constructed for Taylor Milling & Elevator Co., at Lethbridge, Alta.

16840 June 21 Authorizing C.P.R. to close up highway near mileage 48, Edmonton Branch.

16841 June 22 Authorizing C.P.R. to construct spur for Lethbridge Brewing and Malting Co., and Messrs. Young Bros., at Macleod, Alberta.

16842 June 25 Approving plan of track elevation of C.P.R. at North Toronto; subway structures plan for Yonge St. and Avenue Rd. to be filed for approval, etc.

16843—June 17—Refusing application of Quebec Rifle Assn. re C.N.R. stopping trains at Point aux Trembles Range, Montreal.

[illegible] June [illegible] Authorizing C.N.Q. Ry. to cross with its St. Eustache-St. Jerome Line, C.P.R., near St. Augustine, Que.

[illegible] Rescinding Order [illegible], Feb. 15, 1909, in so far as it requires maintenance of agent at Montfort, Que.

[illegible] June 25 Approving plan showing track elevation of joint section of C.P.R. and C.N.O. Ry. from Summerhill Avenue to Dovercourt Rd., except approaches to subways at Yonge St. and Avenue Rd. must be level, Christie Street subway to be full width of street.

[illegible] June 19 Amending Order [illegible], May [illegible], 1912, by striking out words "at Bashaw" in third line of operative part.

16848—June 18—Approving location of G.T.P. B.L. Co. station at Dodsland, on its Biggar-Calgary Branch.

[illegible] June [illegible] Authorizing G.T.P. B.L. Co. to construct series of seven industrial spurs in Regina, Saskatchewan.

[illegible] June [illegible] Naming express delivery and collection limits for town of Shawinigan Falls and Fraserville, or Rivière du Loup, Que.

[illegible] June [illegible] Authorizing T.H. & B. Ry. to construct spur for Barton Lumber and Supply Co., Hamilton, Ontario.

[illegible] June [illegible] Refusing application of city of Ottawa for removal of G.T.R. tracks off Preston Street.

[illegible] June [illegible] Directing G.T.R. to within [illegible] days install electric bell at [illegible] per cent. from Grade Fund.

[illegible] June [illegible] Directing M.C.R. to within [illegible] days install electric bells at [illegible] St. and [illegible] St., Springfield, Ontario, [illegible] per cent. from Grade Crossing Fund.

[illegible] June [illegible] Authorizing G.T.R. to construct spur for Export Lumber Co. [illegible] Preston Street, Ottawa, Ont.

[illegible] June [illegible] Naming express delivery and collection limits for City [illegible]

[illegible] June [illegible] Approving G.T.R. [illegible] plan, Richmond, Que.

[illegible] June [illegible] Approving plan of C.P.R. [illegible] from [illegible] Winnipeg, Man. [illegible]

[illegible] June [illegible] Authorizing C.N.R. [illegible] South [illegible] Saskatchewan.

[illegible] June [illegible] Directing C.P.R. [illegible] Ont., to stop [illegible]

[illegible] June [illegible] Authorizing C.P.R. to construct [illegible]

[illegible] June [illegible] Authorizing C.N.O. Ry. [illegible] County of [illegible], Ontario.

[illegible] June [illegible] Authorizing C.P.R. [illegible]

[illegible] June [illegible] Application [illegible]

[illegible] June [illegible] Authorizing C.P.R. [illegible] traffic [illegible] Saskatchewan.

The Canadian Engineer

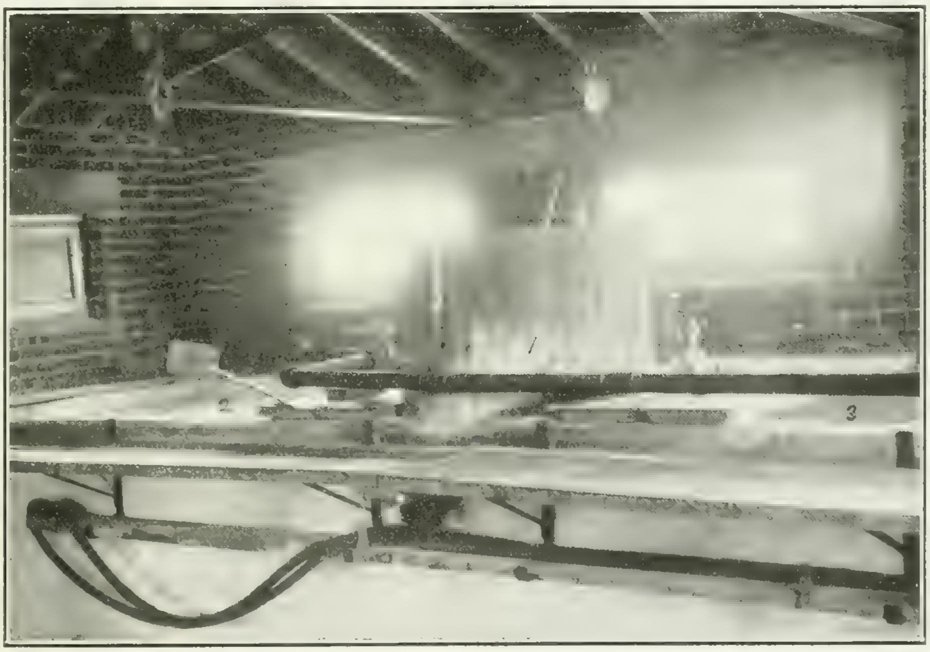
An Engineering Weekly

THE TORONTO WATER CHLORINATION PLANT.

Toronto is supplied by water from three sources, two of which are more or less intermittent. One of these, in East Toronto, where the water supply is obtained from the open lake opposite Balmy Beach, supplies from one-half to one million gallons a day. This water is chlorinated by a small temporary plant of little mechanical interest.

The West Toronto Pumping Station, which formerly supplied the Junction district, is capable of pumping one and a half million gallons of water per day, and draws this supply from the Humber Bay, about 700 feet from shore. As this water is usually contaminated with sewage, it is only operated when absolutely necessary to maintain a sufficient supply of water. This supply is chlorinated by means of injectors attached to the piston rods of the pumps, so that each gallon of water forced into the main is given at the same time a sufficient quantity of chlorine to practically sterilize it.

The main chlorinating plant is situated over tunnel shaft number two on Toronto Island near Hanlan's Point. Formerly the water flowed directly by gravity from Lake Ontario, through a pipe across the Island, and fell into the tunnel at this point. Since the first of January, 1912, however, the water is intercepted by the slow sand filters, through which it passes, and again flows to the tunnel, clarified, and with a large portion of the bacteria removed.



Toronto Water Chlorination Plant. No. 1 shows mixing tank. Nos. 2 and 3, solution tanks.

The plant consists of four tanks, namely, a mixing tank, two solution tanks and a constant head tank, which is divided into two, so that one can overflow into the other, or they can be operated independently.

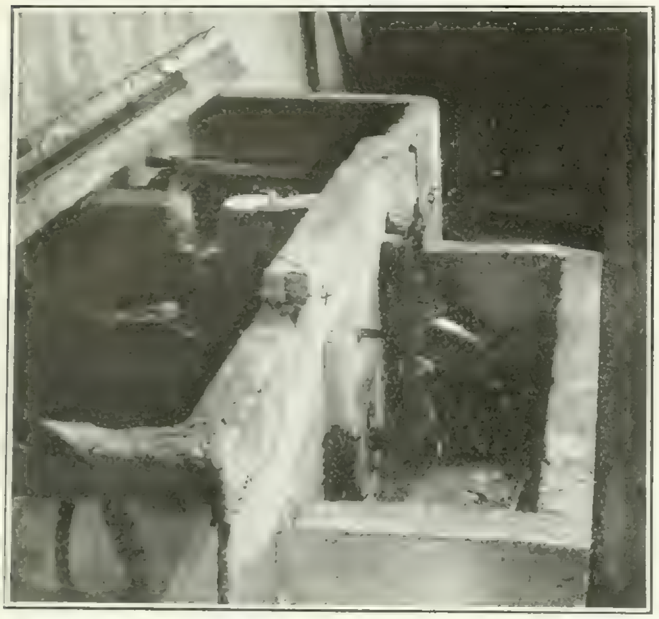
The weighted charge of calcium hypochlorite is placed in the mixing tank, a little water is added, and the mass pounded smooth and then filled to the top with water. The thick milky solution is then run into the solution tank, which is about half-filled with water. The solution tank is then filled, and the mixture stirred at intervals until an hour and a half before it is to be used, so that the sediment can completely settle out. The clear, supernatant fluid, which is alone used, flows into the constant head chamber. At first this was kept at a constant level by a valve operated by a ball float, but not proving satisfactory, a hand valve was substituted. The overflow from the chamber is caught and dipped back into the main tank whenever this becomes necessary.

A calibrated valve allows the solution to flow from this constant head chamber into the pipe leading to the grid in the tunnel shaft. A needle connected to a registering device points out the amount of water flowing along the pipe into the tunnel shaft, the mechanism having been previously calibrated by the amount of water pumped at the main pumping station. The operator opens or closes the gate valve to the proper notch, according to the flow registered by the needle.

The grid consists of a two-inch iron pipe, containing cross arms of ½-inch pipe perforated at intervals. The grid is hung across the stream of water just as it falls into the tunnel shaft, and where it gets a thorough mixing.

The plant is by no means a perfect one, but it has, on the whole, worked satisfactorily since the device for registering the flow of water has been installed. Lake Ontario water is peculiar in this, that the amount of free chlorine required to sterilize the water is very close to the amount which can be detected by taste, i.e., about .3 parts free chlorine per million parts of water. If this amount is reduced, its bactericidal effect is also reduced; if increased, it can be detected by the consumer. The application has, therefore, to be closely watched, and two men are maintained on each twelve-hour shift, night and day, one of whom has always been a chemist, to check up the strength of the hypochlorite, solutions, etc.

The efficiency of the plant may be gauged from the fact that B. coli, though frequently present in the unchlorinated water before the filtration plant was installed, and for some time after, has not been obtained in the laboratory tap since last October, a period of eight months. Fairly high counts have sometimes been obtained in districts supplied by the water after it has been passed through the reservoir or through the high-level pumping station, due to after growths of bacteria, but these are without significance. During May, for instance, the average bacteria count from the laboratory tap on gelatine was only 5 per c.c., which is quite extraordinary. The results seem to prove, moreover, contrary to the experience of Stokes and Hachtel of Baltimore, that the action of chlorine upon B. coli is selective, and that this organism is more readily destroyed than some of the other organisms present.



Toronto Water Chlorination Plant. Nos. 2 and 3, solution tanks. No. 4, constant head tank, and No. 5, calibrated valve.

Toronto Water Chlorination Plant. No. 4 shows constant head tank, and No. 5, the calibrated valve.

[illegible]

[illegible]

45 per 100,000, it was only 20 per 100,000 in 1911, in spite of the fact that for several weeks in 1911, on account of a broken intake pipe, consumers had to drink bay water, heavily contaminated with sewage.

BRITISH COLUMBIA

Application is being made by the International Railway and Development Company for a water right on the Fraser River and for a license to dam that river at a point above Yale at what is known as the canyon. The company is a new one, and the idea is also new. Local men are interested, the names of Mr. H. H. Stevens, M.P., Mr. E. W. Leeson, of Vancouver, and Mr. H. T. Thrift, of Ladner, are mentioned, with Mr. D. M. MacDuff as the company's consulting engineer. It is stated that $5,000,000 is immediately available for development purposes, and that capital up to $20,000,000 will be supplied from Great Britain. The plan outlined is to construct lines of electric railway throughout the lower mainland.

Waterpowers abound at different points on the lower mainland, close to Vancouver the centre of activity and where the biggest market for electrical energy would be found. The promoters of the company must be optimistic, or are building on securing money from Great Britain and going ahead with the project for what there is in it. At present, the field seems covered by the British Columbia Electric Railway Company and the Western Canada Power Company. The British Columbia Electric Company is constantly increasing its supply and building reserve auxiliary plants to obviate any serious loss or inconvenience loss to its patrons through a breakdown of any of its units. Still it is aggressively in the field after business, indicating that it is able to furnish power for more customers. The Western Canada Power Company has its plant thirty-five miles east of Vancouver, considerably less than half the distance to the Yale canyon of the Fraser. This company has spent three million dollars developing the power on the Stave River and is now supplying electrical energy for industrial purposes. It has a very large amount yet to place before it will have exhausted its capacity. To secure use for its power, the company has agitated the construction of an electric tram line between Vancouver and Mission, paralleling the Canadian Pacific Railway. It was in connection with the financing of this that Mr. John Hendry sounded the London market when in the Old Country in the spring.

In addition to these operating plants close to the lower mainland market, or rather in it, there is power on the Lillooet River, this side of Stave River, which has often been suggested but as yet undeveloped. There is a magnificent power on the Squamish River, a little over thirty miles from Vancouver, at the head of Howe Sound. Then there is the big power at Powell River, 80 miles up the coast, where the pulp and paper mills of the Powell River Pulp and Paper Company are located. All these are easier of development than the Fraser canyon proposition, though there is no denying the fact that once a dam was built to withstand the turbulent flow of that mighty river at its flood a great amount of power would be available. To secure adequate returns on their money, the company must expect a large increase of population on the lower mainland. In the meantime, the companies already established will not have been inactive. There is no field north or east of the city proposed, so that what power is placed would have to be utilized in the district lying between Yale and Vancouver. The scheme is no doubt feasible from an engineering point of view, though the construction of a dam to restrain the Fraser will be no easy task. The proposal is certainly speculative.

THE VALUE OF A CONTINUOUS SETTLING BASIN.*

By Alexander Potter.†

The City of Muskogee, Oklahoma, has under construction a number of improvements to its water supply and sewerage systems. The water improvements consist of an intake tower in the Grand River some 2,000 ft. above its junction with the Arkansas River, a 54-in. concrete-lined intake 2,500 ft. long constructed in rock tunnel under the Arkansas basin, the installation of additional pumping units, a water purification plant, the reinforcement of the water distribution system, and a 6,000,000-gal. equalizing reservoir, consisting of a 50-sided polygon whose walls are built entirely above the ground. That portion of the water purification plant now under construction is sedimentation assisted by coagulation with ferrous sulphate and lime. Provision is made so that ultimately mechanical filters can be introduced if they should be found necessary. In this article the settling basin only will be discussed.

The new settling basin is a reinforced concrete structure, 212 ft. square on the inside. When filled to a depth of 18 ft. this basin holds over 6,000,000 gal. A curtain-wall of reinforced concrete divides the basin into two compartments. The first or smaller of these compartments, 212 ft. long and 52½ ft wide, has its bottom perforated and underdrained. A distributing trough, supported upon the counterforts, extends the entire width of the first compartment. The water enters the first compartment from the distributing trough through a series of 8-in. openings spaced two in each panel formed by the counterforts; the counterforts are on 13 ft. 4 in. centres. A 4-in. concrete baffle or stilling-wall in front of the distributing trough extends the extire length of the basin. The water passes through the first compartment over the curtain-wall into the larger compartment. Balanced valves in the bottom of the curtain-wall equalize the pressure on the wall during filling. A collecting channel of the same size as the distributing channel is located at the far end of the basin. The water enters this collecting channel through a series of 2-ft. weirs located one in each panel. The basin is designed to operate continuously.

Advantages of Continuous Settling.—A settling basin operating continuously possesses a number of advantages over a basin which is operated intermittently. There is first a considerable saving in the size of the settling basin. This saving may amount to as much as 50 per cent. over an intermittent installation in which two basins are used, decreasing, of course, somewhat with the number of basins. When a settling basin is operated continuously, the capacity of the basin, except for the sludge displacement, is always available, which is not the case with the intermittent type. There is no reason why in a properly designed basin the settling efficiency should be impaired by the disturbance at the inlets and outlets.

Removal of Sludge.—At the Muskogee settling basin the sludge from the first or smaller compartment is removed without interfering with the efficient continuous operation of the plant by a system of underdrains in the small compartments. These underdrains consist of 3-in vitrified pipe drains, each perforated with a hole 9/16 in. in diameter. The underdrains are laid with Pioneer asphalt joints, and are arranged in five zones. The collecting channel for each zone is 8 in. deep and 14 in. wide. Each channel is covered with a 24-in. square reinforced concrete slab, perforated with a 9/16-in. hole in the centre.

The sludge valves are 12-in. hydraulically-operated valves of the Rensselaer make. Each valve controls a zone approximately 212 ft. long and 10½ ft. wide. In each zone are 405 perforations, each 9/16 in. in diameter, spaced 2 ft. on centres in rows 27½ in. apart. As the amount of sludge deposit depends principally upon the distance from the distributing trough, the arrangement of the zones is such that the sludge will be fairly uniformly deposited over the area of any one zone.

Operation.—The intervals between openings of the valves and the length of time they remain open at the outlet end of the sludge drains will vary with the condition of the raw water. The precipitated solids should not be allowed to accumulate long enough to pack over the openings. The sludge valve should be closed at once when the discharge, which is visible at all times, begins to show up clear. After the sludge is drawn off there is formed a cone-shaped depression in the deposit at each perforation. Between the perforations some of the sludge is left standing in the form of wedges and pyramids. Assuming a side slope of 45 deg. for the sludge, which is considerably steeper than most sludges stand in water, the amount of sludge that is out of reach of the underdrains in this particular case would cover the bottom, if considered uniformly distributed, to a depth of 6 in. This means a decrease in the capacity of the first compartment of approximately 2.8 per cent.

Great care should be exercised in the design of a system of underdrains such as has been outlined to insure its successful operation. The underdrains and perforations must be designed so as to give the same amount of suction for all of the perforations or holes in any one zone. Otherwise, clean water will be drawn in at those points where the suction is greatest, while sludge is still covering a large part of the opening. Such a condition not only leads to a great waste of water, but results sooner or later in the partial clogging of the perforations, and ultimately in the permanent breakdown of the underdrain system. To be efficient, the water must enter the perforations at as high a velocity as it is practicable to obtain. This means that, especially in a shallow tank, the frictional losses in the underdrains and effluent pipes and the velocity head at the discharge end must be kept down as much as possible. In the average plant the area of each valve should approximate the total area of the perforations tributary to the valves, preferably less, although this proportioning is claimed to be protected by patents. Quick-opening valves should also be used for economy. Ample provision should be made to prevent excessive pressures developing in the effluent pipe from water hammer. Valves 8 in. or smaller can be readily operated by hand; larger valves should be either hydraulically or electrically operated.

This system of sludge removal was installed by the author at McKeesport, Pa., and Georgetown, Ky.

The larger compartment of the settling basin comprises three-quarters of the total capacity of the basin. It has a sloping bottom draining to a sump. A 12-in. cast-iron sludge pipe is carried from this sump to a 24-in. vitrified pipe drain located outside of the basin. It is expected that fully 85 per cent. of the suspended solids will settle out in the first compartment. For this reason it was considered unnecessary to underdrain the larger compartment. Whenever the sludge reaches a depth of several feet or more in the larger compartment the operation of the basin will have to be suspended and the basin cleaned. The turbidity of the river water, however, is normally low, and it is not expected that this will happen more than once in several years.

The cost of constructing the underdrain system for the removal of sludge is not great when compared with the economy resulting in the cost of operation. By removing the sludge daily the capacity of the basin is not impaired as is the case when the deposits are allowed to accumulate. The emptying and cleaning of a basin is a costly operation, especially in winter time, and is to a very great extent avoided even if only a portion of the basin is properly underdrained.

---

* Abstract of paper read before American Waterworks Association at thirty-second annual convention, Louisville, Ky., June 3-8, 1912.

† Consulting Engineer, New York City.

Water Required in Cleaning.—The amount of water that passes off with the sludge in the system just described for Muskogee, it is estimated, will not exceed one-sixth of 1 per cent. of the water treated.

Discussion of Reinforced Concrete.—The basin is being constructed of reinforced concrete. It is possible to construct a monolith of considerable proportions of plain concrete. However, it is but a question of time when the unequal settlement of the foundation, always possible except when the foundation is solid rock, and the shrinkage and temperature stresses set up in the mass, destroy the continuity of the structure. On the other hand, it is possible to construct and maintain as such, a reinforced concrete monolith of very large proportions.

There appears to be some doubt that thin sections of reinforced concrete are suitable for water-tight structures. There need be no fear whatever that there will be any trouble if the work is carried out as it should be. The water-tightness of concrete depends principally upon the amount of cement present, provided the sand and stone or gravel are properly proportioned. Six bags of cement per cubic yard of concrete is ordinarily sufficient to produce a water-tight mixture. This amount, however, should be increased when the hydro-static head is considerable.

The author is opposed to the use of waterproofing ingredients or waterproofing applications. Both increase the cost of the concrete work considerably. It is far better to put the value of the waterproofing materials into the concrete itself by adding more cement. The use of a waterproofing ingredient or application tends to poor construction work, the contractor counting upon the waterproofing to help out careless construction.

The author, from his study and experience in the construction of tanks and reservoirs, has reached the conclusion that leakage may be due to any one of the following causes:

(1) Faulty construction, (a) Lean and porous concrete work. (b) Inexperience and carelessness in carrying out the construction.

(2) Faulty design. (a) Weak details at the connections. (b) Excessive secondary stresses at connections. (c) The use of too high unit stresses in steel and concrete.

Faulty construction can be rectified to some extent, but often only at a considerable cost, by waterproofing the structure from the inside. Leaks developing through faulty design are, on the other hand, always difficult to master, and in many cases very little can be done to remedy the unsatisfactory condition of the completed structure. To guard against the production of lean concrete work, the author's specifications provide that all cement used in the work should [illegible]

As 10 ft. of the basin is constructed below the original [illegible] widening out to 18 ins. at the bottom. The floor [illegible] will however, be an expansion joint between the present [illegible]

[illegible]

both plain and reinforced, especially with reference to the conditions under which such construction has given more or less trouble.

Details of Design of Basin.—The success of a reinforced concrete structure of any magnitude depends primarily upon the thoroughness with which the various structural details, especially the connections, are worked out. The connections should receive the same careful attention that is given them in structural work. The author, therefore, thinks it advisable to dwell as some length upon the design of the structure.

The Muskogee basin is being constructed of gravel concrete. The gravel is washed river gravel obtained from the bed of the Arkansas River. Its size is limited to 1 in. in the side walls and counterforts, and to 2 ins. in the bottom. The sand is a very coarse river sand, obtained from the same river. It is clean, coarse and sharp, and makes a splendid concrete sand. The concrete is being mixed approximately in the proportion of one part of Portland cement, two parts of sand, four parts of gravel. The mixture is changed slightly from time to time to meet slight changes in the quality of the aggregate.

In the design of the structure, the unit stresses were assumed as follows:

fc = The maximum allowable working compression in the concrete in flexure, 650 lbs. per sq. in.

fs = The maximum allowable tension is the steel, 14,000 lbs. per sq. in.

v = The maximum intensity of transverse shear in concrete (assuming a uniform distribution of the shear) 50 lbs. per sq. in.

u = The maximum working adhesion or bond stress between the concrete and deformed bars, 80 lbs. per sq. in.

e = The ratio of the modulus of elasticity of steel to concrete, 12.

These values are conservative. They limit the percentage of the steel to be used in the structure to 0.83 per cent. of the area of the concrete above the steel.

The following equations, with numerical constants, have been developed in accordance with the now universally recognized theory:

$$q = \sqrt{\frac{M}{8.54}} \qquad \text{(Equation 1)}$$

$$As = \frac{M}{1020 \times q} \qquad \text{(Equation 2)}$$

Where q is the distance from the compression side of the beam to the steel, known commonly as the effective depth of the beam; M is the bending moment in foot-pounds per inch width of beam, and As is the area of the steel required.

Equation 1 gives the effective depth of the beam when the bending moment is known and the reinforcement is fixed at 0.83 per cent. of the area of the concrete above the steel.

Equation 2 gives the amount of the steel reinforcement when the bending moment is known and the depth of the beam (q) is fixed. It can only be used when the percentage of steel reinforcement is 0.83 per cent. or less.

Design of Side Walls.—The reinforcement in the side walls and their construction make them partially continuous. The common theory of flexure as we know it is applicable to this case, but not with the numerical constants familiar to us. The allowance that is usually made in reinforced concrete construction for the increase in strength due to the partial continuity is a reduction of from 25 to 50 per cent. of the bending moment computed on the basis of a simple beam. The exact amount of the increase in strength due to partial continuity can be computed in any one case when all the factors are known. The process, however, is a very tedious one, and entirely unnecessary. A fair assumption as to the allowance can nearly always be made. In this case, on account of the small amount of reinforcement in tension over the counterforts, this reduction has been taken as 25 per cent.

For the design of a tank, equations 1 and 2 can be put in a more convenient form, as follows:

Replacing M by its value $\frac{(w \times X \times L)^2}{10 \times b}$, where w is the weight of the water, 62½ lbs. per cu. ft., X the depth of the water, L the clear span between counterforts, b the width considered, namely 12 ins., we get,

$$q = 0.247L \times \text{square root of } X \qquad \text{(Equation 3)}$$

$$As = \frac{(.00051XL)^2}{q} \qquad \text{(Equation 4)}$$

Equation 3 gives the minimum effective depth of the beam or slab at any depth (X ft.) below the surface of the water. Equation 4 gives the amount of the steel reinforcement required per inch width of beam when the effective depth (q) is fixed. It cannot be used, however, when the percentage of steel reinforcement exceeds 0.83 per cent.

Maximum Intensity of Pressure 1125 lbs per sq ft
a
b

Fig. 1.—Diagram of Forces Acting on the Walls.

Figure 1 shows the forces that are acting on the walls. The water pressure increases from zero at the water surface to a maximum of 1,125 lbs. per square foot at the bottom. Only a portion of this pressure, namely, that portion marked a, is carried by beam action to the counterforts. That portion marked b and shown by the dashed arrows, is carried by cantilever action directly to the footing. The diagram shows that the walls receive their maximum stress as a beam at a point approximately 15 feet below the water level. The minimum thickness of concrete wall that it is possible to use under the conditions assumed is computed as follows from equation 3: Substituting in this equation, we have

$$q = 0.247 \times 12.08 \times \text{square root of } 15 = 11.55 \text{ ins.}$$

Allowing 2½ ins. of concrete to cover the steel, we obtained a minimum thickness of 14 ins. The plans show the thickness of the wall at this depth to be 17 ins. On account of the low cost of the concrete materials and the comparatively high cost of the steel reinforcement, it was deemed more economical to use a heavier section than the minimum that could be used. In places where concrete materials are costly, it would be possible to construct the side walls 8 ins. thick on the top and 15 ins. thick at the bottom.

The amount of steel reinforcement, As, that would be required 15 ft. below the water level can be readily obtained by means of equation 4: $As = \frac{.00051XL^2}{q}$.

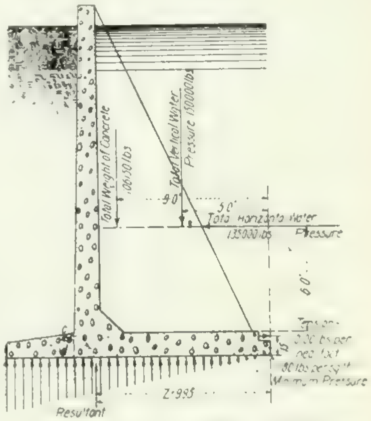
Substituting for X, 15 ft; for L, 12.08 ft., and for q, 14.64 ins., we obtain, As = .0763

The spacing of ¾-in. round rods will be .4418 (the area of a ¾-in. round rod divided by .0763 (the amount of steel required per lineal inch), giving 5.79 ins. as the spacing. The drawing shows the spacing to be 5.5 ins. at this point.

In Fig. 1 is shown graphically by dotted arrows the earth pressure acting against the wall from the outside. It is proposed to back up the walls of the basin on three sides, as shown on the plan. As there is a possibility that this backing may be removed at any time, no allowance whatever has been made for the additional stability given to the tank by this backing.

Attention is called to the connection of the walls of the tank to the bottom. The pressure from within forces the side walls outward, the deflection reaching the maximum half-way between the counterforts. The connection of the walls to the footing must be either a sliding joint to permit of this movement, which is impracticable, or sufficient reinforcement must be provided to prevent the possibility of rupture at this point. Fig. 1 shows diagrammatically, but in a somewhat exaggerated form, the deflection of the side walls at the centre of the span when the reservoir is full of water. The rigid connection spoken of is a concrete fillet 18 ins. on the side, reinforced with ½-in. round bars spaced 12 ins. on centres. This rigid connection transfers by cantilever action some of the hydrostatic pressure against the lower portion of the wall directly to the footing. The amount of this pressure transfer is shown diagrammatically by the dashed arrows in Fig. 1, marked b.

Figure 2 shows all of the forces except the earth pressure, acting on a section of the tank 13 ft. 4 ins. long, including one counterfort and half of the clear span of the walls on either side of it. The total weight of the concrete for this section is 106,150 lbs., with its centre of gravity located 9 ft. from the heel (o) of the footing. The total horizontal water pressure against this part of the tank is 135,000 lbs. and the weight of the water resting on the footing is 150,000 lbs. Let us assume for the present that the sliding of the wall is prevented by the tension in the bottom. This tension amounts to 10,100 lbs. per lineal foot of footing and is shown acting 1.25 ft. above the bottom of the footings. All these forces are shown in their true positions in this figure.



Total Weight of Concrete 106150 lbs

Resultant

Fig. 2.—All Forces Acting Except Earth Pressure.

Since the forces shown acting on this portion of the structure are in equilibrium, we have

$$z - \frac{\Sigma Mo}{\Sigma W} \text{ or}$$

$$\begin{aligned} 106{,}150 \times 9 &= +955{,}350 \\ 150{,}000 \times 5 &= +750{,}000 \\ 135{,}000 \times 7.5 &= 1{,}012{,}500 \\ -135{,}000 \times 1.25 &= -168{,}750 \\ \hline \Sigma M &= 2{,}549{,}100 \\ z &= 9.95 \\ \Sigma V &= 256{,}150 \end{aligned}$$

This shows that the resultant pressure on the footing, namely, 256,150 lbs., pierces the base 9.95 ft. from the heel, which is practically two-thirds of 15⅓ ft., the width of the base. Consequently, the distribution of the foundation pressure on the footing is in the form of a triangle, about as shown in the figure. It reaches a maximum pressure of 2,300 lbs. at the toe and nearly zero at the heel. Sufficient steel is provided for in the bottom to take care of a tension of 10,100 lbs. per lineal foot of footing where it joins the 6-in. concrete bottom. This reinforcement consists of ⅜-in. round rods spaced 6 ins. centres. The plan erroneously shows these bars to be placed 12-in. centres. This amount of steel is sufficient to resist this tension at a unit stress well within the elastic limit of these steel bars. The author does not wish to convey the idea that this tension is developed to the extent shown in Fig. 2. A very large proportion of it will be developed by friction between the footing and the supporting earth, and some by the earth backing, which, however, will not be always present.

Design of Counterforts.—Figure 3 shows the forces acting on the counterforts proper. The reaction of the walls, tension in this case, amounts to 93,500 lbs., and its distribution is about as shown in the figure. It reaches its maximum 15 ft. below the water level. This tension is taken care of by thirty-two ½-in. round bars at an average unit stress of 14,900 lbs. This is not a very high value. In the discussion we have ignored the additional stability received from the earth pressure, and also the tensile strength of the concrete in the counterforts, which may be considerable.

The greatest of care must be taken to anchor the walls to the counterforts. In this case, this has been done by threading the ends of the ½-in. tension bars and fastening them with double nuts to two 2½-in. by ⅜-in. plates, 18 ft. long, embedded in the walls, as shown in the reinforcing plan. The object of the double nut is to prevent the possibility of play at the joint.

A study of this figure shows that the counterfort is not a cantilever at all. In a cantilever, the internal resisting forces acting on the plane yz, must balance algebraically, that is, the total tension must be equal to the total compression. This is not the case in the counterfort, as can be readily seen. The forces that act on the counterfort are as follows:

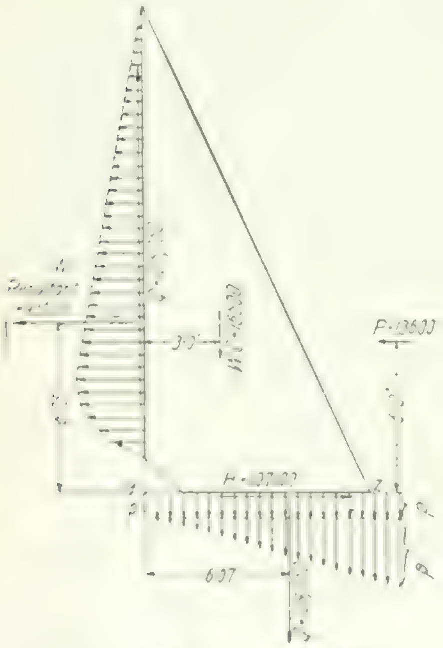

Fig 3.- Stresses Acting on the Counterfort Proper.

W, the tension exerted by the walls on the counterfort, 93,500 lbs.

P, the horizontal pressure of the water acting against the counterfort proper, 13,600 lbs.

W¹, the weight of the counterfort proper, 16,500 lbs.

Q, the total tension between the footing and the counterfort along the plane yz, 109,250 lbs., shown acting 6.07 ft. from the point y.

Q¹, the shear between the counterfort and the wall of the basin, 109,250 lbs. plus 16,500 lbs.

R, the horizontal shear acting along the plane yz, 109,250 lbs.

The determination of the resultant tension Q and its distribution with reference to the plane yz, is a very interesting one, and is for this reason given in detail. Taking moments about the point y, we obtain the following equation:

[illegible]

In this equation, there are two unknown quantities, p and p¹. A safe assumption to make, since there is no tension at the heel (c) is that p + p¹ cannot exceed the sum of the weight of the water above the footing and the weight of the concrete itself. This amounts to 1,350 lbs. per square foot of footing, thus giving the additional equation

$$p + p^1 = 1350 \times 13.33$$

From these two equations we obtain

$$p = 3,850 \text{ lbs. and}$$
$$p^1 = 14,150 \text{ lbs.}$$

The total resultant tension Q, and its location, can now be readily found, and is given in the figure as 109,250 acting 6.07 ft. from y.

This tension of 109,250 lbs. is taken care of by sixteen ⅞-in. round bars at an average unit stress of 11,350 lbs. The maximum stress in these bars probably reaches 14,000 lbs. per square inch. The bars are anchored in the concrete footing by two 2½-in. by ⅜-in. plates 8 ft. 6 ins. long, to which they are fastened by double nuts.

The distribution of the pressure along the plane yz is a more or less indeterminate one. It depends principally upon the shape and the reinforcement of the footing course. Only in a very special case will its distribution be such as to make the counterfort a cantilever. The method so often followed of designing a counterfort as a cantilever and placing all the steel reinforcement in the back of the counterfort, is an erroneous one. It places in the footing course a concentrated and rather high tension, and at a point where it cannot be properly taken care of, thus producing enormous secondary stresses in the footing, which would be a serious defect in the structure.

Design of Corners.—The reinforcement of the corners of the settling basin is of some interest. This reinforcement consists of a triangular concrete fillet 24 ins. on each side, reinforced with ⅜-in. round bars, each 6 ft. 3 ins. long, and spaced the same as the ¾-in. horizontal reinforcement in the walls of the basin. The adhesion between the steel and the concrete is counted upon to securely tie in the corner. No rigid connection whatever is used for the reinforcement.

Design of Footings.—The footing overhangs the wall for a distance of 4 ft. It is 18 ins. thick at this point where it joins the wall and narrows down to 12 ins. at the outer end. The following computations give some idea as to the methods used in designing this footing.

The upward pressure on the overhanging portion ranges from 2,300 lbs. per square foot to 1,750 lbs. per square foot. The thickness of the footing at c-d, Fig. 2, should be sufficient to keep the shearing stress down to a safe working value. The total upward pressure per lineal foot of footing course, amounts to 8,100 lbs. This gives an average value for the shear of 37.5 lbs. per square inch—a very safe value. Equation 2 can be used to compute the amount of steel required, as follows:

$$As = \frac{M}{1020 \times q}$$

where M represents the bending moment in foot-pounds per lineal inch of footing at the plane c-d, which amounts to 1,410 foot-pounds.

q is 18 ins. minus 3 ins.

Substituting in this equation, we obtain for As, 0.0922 sq. ins. This amount of steel requires a spacing of 4.80 ins. for ¾-in. round bars. A spacing of 6 ins. is shown on the plans. This spacing used is considered ample, as the computations just outlined do not take into consideration the weight of the overhanging footing nor the weight of the earth backing.

The above general outline of the methods used in designing the settling basin conveys some idea of the thoroughness and carefulness with which a structure of this type must be designed.

Horizontal construction joints are used freely. The unfinished surface is always left in as rough a condition as possible, but never roughened up after the concrete has partially set. The author has found that this roughening often loosens the stone in the concrete, but not sufficiently so that they can be removed, a condition which is apt to impair the water-tightness of the structure. To start a day's work, the surface is thoroughly cleaned with wire brushes and water, and a cement liquid mortar mixed in the same proportions as the mortar in the concrete, is poured over the old work to a depth of ½ in. This method always gives a good water-tight horizontal construction joint.

Vertical joints are permitted only in certain places, as these joints are very difficult to make water-tight. All vertical joints in the walls are made directly over the counterforts.

The specifications call for two coats of neat cement wash to be applied with a white-wash brush on the inside of the basin. Both of these coats are to be applied to the concrete when damp but not wet, and the second coat must be applied before the first one has had time to get very hard. Any leakage that may develop in the basin previous to its final acceptance must be repaired by the contractor, at his own expense, no additional compensation whatever being permitted for this work under the specifications. The contractor, realizing the importance of doing conscientious work all the time to prevent subsequent trouble from leakage, is producing a first-class structure. The work is beind done so thoroughly that very little leakage, if any, is expected when the basin is filled for the first time this summer.

The contract for the construction of the basin was let to W. W. Fuller, of Muskogee, Oklahoma. The following is an approximate estimate of the quantities of material required, together with the contract unit prices:

18,000	cu. yds. of earth excavation at $0.40	$ 7,200.00
1,930	cu. yds. 1:2:4 concrete at $6.25	12,062.50
820	cu. yds. 1:3:6 concrete at $5.40	4,428.00
4,000	bbls. of cement at $1.40	5,600.00
220,000	lbs. of steel at $0.035	7,700.00
3,520	ft. 3-in. vitrified sewer pipe at $0.20	704.00
800	ft. 6-in. vitrified sewer pipe at $0.20	160.00
220	ft. 24-in. vitrified sewer pipe at $3.50	770.00
1	manhole complete	50.00
160	ft. 12-in. cast iron pipe at $2.25	360.00
40	ft. 18-in. cast iron pipe at $4.00	160.00
380	ft. 36-in. cast iron pipe at $8.00	3,040.00
28,000	lbs. cast iron specials at $0.05	1,400.00
5	12-in. gate valves at $10.00	150.00
6	18-in. press. equalizing valves at $12.00	72.00
1	24-in. tidal valve at $18.00	18.00
485	ft. 1½-in. pipe railing at $0.60	291.00
	Superstructure for valve chamber	500.00
1,000	lbs. wrought iron and steel at $0.05	50,00
300	ft. ¾-in. galv. w. i. pipe at $0.30	90.00
	Total	$44,805.50

The imports of iron and steel from the United States for the fiscal year ended March 31st, 1912, totalled $36,382,725, as against $29,307,039 for the previous year. This total does not include machinery, agricultural implements, nor many other articles properly classified as iron and steel. The gain in imports from the United States the last fiscal year in the above items of iron and steel was $7,075,686, or more than 27 per cent.

SOME NOTES ON BAND CONVEYORS.

By F. Tissington.

This is the first of a series of articles by Mr. Tissington on Band Conveyors.—Editor.

At the present time band conveyors are used for conveying all kinds of material, and they can be found scattered all round the world generally fulfilling their duty comparatively with little cost for maintenance providing the original designing of their various parts has been carefully considered to suit their requirements.

The following is a list of a few of the uses to which they have been put and this is only given to show their adaptability.

In collieries, docks, store yards, storage bins, etc., for transportation of coal from one point to another, also for the purpose of cleaning and sorting same into various grades.

In gasworks for charging retorts, conveying coke and other substances.

Also for the conveyance of all kinds of earth, clay, rock, ore, sand, gravel, cement, plaster, paper and pulp.

They are also used for transporting sugar, wet charcoal, grain of all descriptions, postal packets and letters, and even invade our workshops to handle small repetition parts collecting same from the machines and delivering them to the store or any other point desired.

There are, of course, dozens of other purposes for which they are or can be utilized, and if any manufacturer has a conveying problem of any kind that involves any quantity of hand labor he would do well to consider the idea of installing either a band conveyor or a mechanical conveyor of some other type, because of all costs in the process of manufacture, generally speaking, that of hand labor is the highest, and a machine, unlike the ordinary human being, does not require to stop for a time every now and again to rest a while. A little oil and a small amount of adjustment occasionally being sufficient.

Its adaptability is again emphasized by the fact that it will not only run horizontally in one direction but may be made to reverse the direction with very little additional gear. Also it may be inclined to almost any angle, depending, of course upon the nature of the material and the construction of its top surface.

For instance, the writer has known of one conveyor working at about forty degrees with the horizontal conveying flat packages, the only addition to the ordinary type being a number of wooden slats bolted on to the working surface of the belt to prevent the packages sliding down the incline. Going further still, we find the band conveyor turned into an elevator with buckets attached to the band and working vertically.

The construction of these belts is very simple, consisting only of two terminals, generally one being the driving end and the other the tension end, the supporting rollers for the carrying and return sides, the belt itself, and the framing to carry the gearing and rollers.

Sometimes, however, the gearing may be placed with advantage in the middle of the belt owing perhaps to this position being near the source of power for driving same, but this is by no means usual. If this is done, it is generally necessary to arrange the driving drum on the bottom or return strand.

Further, it is practicable to arrange the driving gear at either the loading or delivery end, but where possible it is an advantage to place it at the delivery end especially in long conveyors.

The tension gear may be either of an adjustable screw design or an ordinary weighted tension, and this, like the driving gear, may be placed almost anywhere taking into account, of course, local conditions and the general disposition of the plant. It is preferable in the case of long conveyors to use a weighted tension as there is a certain amount of lengthening and shortening of the fabric of the belt due to atmospheric conditions, and this alteration in the case of a long belt would necessitate constantly adjusting the tension gear if it was of the screw type, whereas with the simple weighted tension this arrangement automatically makes its own adjustment. The weighted tension gear has also another advantage and that is, it is impossible for the attendant to overstress the fabric which could be done with the other type.

The supporting rollers, idlers, as they are usually called, are made in various designs according to the fancy of the manufacturer or purchaser, but, generally speaking, they consist of a roller, or series of rollers, mounted on a spindle carried in bearings having grease lubrication. If a troughed top strand is required, each set of rollers is then generally made up of a series of small ones, some being set at the necessary angle to form the top strand into the trough shape. This type is much to be preferred to the conical roller all in one piece as the full width of the band is travelling at the same speed all across its surface. But on the roller either the outer edge of the cone is travelling faster or the smaller diameter is not running as fast as the band, and this sets up quite a considerable amount of friction liable to wear the band out very rapidly. The return strand is always carried on flat rollers similar in construction to the top rollers.

Some firms make a practice of putting in guide rollers. These are set at right angles to the edge of the belt and are intended to keep the band running true on the rollers. These are generally omitted on belts of short length and a common practice is to place a pair (one on each side of the belt) about every sixty feet. It is claimed that these are necessary owing to the belt having a tendency to run up the inclined rollers forming the trough in a similar manner that an ordinary driving belt keeps in the centre of a crowned face pulley.

Another method adopted to keep the belt in line is to set the top idle rollers at a very slight angle with a line drawn at right angles to the length of the band, that is, one would be set slightly out of line one way and the next the opposite way.

The conveying bands are manufactured in a number of [illegible] woven cotton, canvas or duck, either plain or impregnated with some kind of waterproofing material such as Salata, tar, or rubber coating. For most purposes, however, a rubber impregnated belt with an additional rubber covering will give the best results, as this [illegible] a belt impervious to water. If the belt is being continually exposed to the action of rain it will soon rot away. Further, the rubber covering is a factor in preventing an undue lengthening and shortening [illegible] atmosphere. [illegible] the life of the rubber covering [illegible] the life of the belt as a whole, even [illegible] quarter of the [illegible]

[illegible]

[illegible] ordinary cotton belt used as a picking conveyor for coal at a colliery only lasted about seven or eight months, and the expense of renewing it so often made the maintenance cost very high, but rubber faced belts used for similar purposes will last you two, three and perhaps four years if they are properly handled.

There seems to be quite a difference of opinion as to the desirability of making the belt of even plies right across its width, or of reducing the plies in the centre of the belt and thickening the rubber facing.

The general practice in this country seems, however, to lean towards the even ply belt, whereas in England the reverse is the case.

The writer's opinion inclines towards the uneven ply belt with an additional thickening of rubber in the centre where all the abrasive action takes place, because as soon as this protective covering is destroyed the final destruction of the belt is soon brought about. It is a good plan to overhaul the belt periodically and repair any bad cuts with a good stiff rubber solution; also where any sand or grit slobs have been made under the surface they should be taken out and the cut repaired in a similar manner.

If this is done it will be found that the life of the belt will be much longer and will repay the expense incurred. The rubber coating varies from about one-sixteenth to a quarter of an inch, and the ples of the canvas or duck vary from about three to seven or eight according to the kind of material to be conveyed, the width and the length of the belt.

If material of a sticky or wet nature is being conveyed it is a wise plan to arrange a brush under the delivery shoot to clean the face of the belt, otherwise rapid wear is liable to take place owing to the gritty matter being carried round on the underside and thereby come into contact with the snub or gripping rollers and the bottom guide rollers. Further, this grit is likely to get into the bearings of the rollers and cause trouble with these also.

Another good point in an installation of this kind is to avoid all sharp reverse bends of the belt as far as possible, although sometimes this is not altogether practicable. The framing for these conveyors is generally of a very simple character simply consisting of cross supports for the rollers carried on longitudinal stringers of iron or steel. The latter are usually made to suit the general layout of the rest of the structure.

When starting to design a plant it is necessary to know the kind, quantity, general size of the material required to be handled, the magnitude of the largest pieces; whether the material is of a sticky or wet nature. The general layout of the surrounding structures. The points at which the material will be loaded on the band and also where it is required to be delivered, and the relative elevations of these two points, if they are not at the same height. Also whether it is proposed to drive by electric motor, steam engine, or from an existing shaft, and if the latter is the case, the size, speed and direction of rotation should be given and the position of same should be shown on a small sketch in relation to the rest of the other particulars required as to the location of the belt and the surrounding plant. With this information it will be possible for the designing engineer to submit a scheme suitable for the purpose required.

Having now got a general idea of the uses of belt conveyor installation with some of its general features, it is proposed to discuss a few of the smaller parts and then give some data on the capacities, horse-power required to drive same, etc.

THIRTY YEARS' PROGRESS IN THE ELECTRIC FURNACE.*

By F. A. J. Fitzgerald.

There has been so much written about the electric furnace since it entered into regular commercial use about 20 years ago that the presentation of a paper on the subject treating it in a general way is not apt to be interesting. But a promise to attempt the preparation of such a paper having been given, it was thought that there might be some interest attaching to a review of the development of some furnaces during the past 30 years. Moreover, it is often useful to look back over ground that has been covered in order to obtain suggestions as to the best direction to be taken in attempting further advances.

It is now 30 years since Sir William Siemens melted about 20 pounds of steel, as well as platinum in notable quantities in an electric furnace with which he had been experimenting since 1878, and since then the electric furnace has so far developed that there are great numbers, both in Europe and this country regularly engaged in the commercial manufacture of steel. While it is true that others had made some use of electrothermic methods at a much earlier day, for example Despretz, whose source of current was 600 Bunsen cells, yet Siemens' furnace must be considered the first really practical one, coming as it did after the invention of a cheap source of energy—the electric generator.

Siemens' work is of particular interest because he saw the possibility of using the electric furnace for steel manufacture, and, so far as the principles are concerned, they are the same as those in actual commercial use to-day. One of his furnaces was made of a graphite or other refractory crucible enclosed in a jacket of heat insulating material. Inserted in the bottom of the crucible was an electrode of iron, platinum or carbon, while passing through the cover of the crucible was another electrode. The latter was connected to automatic regulating device consisting of a solenoid, this serving to vary the length of the arc and thus keep the rate of generation of energy constant. In working the furnace the steel or other metal was introduced into the crucible and made contact with the lower electrode, while an arc was drawn between the upper electrode and the charge. In such a furnace Siemens melted steel in quantities of more than 20 pounds.

In another form of electric furnace devised by Siemens, the electrodes entered the crucible in a horizontal direction near the top and opposite one another so that an arc was formed between them and heated the charge below by radiation.

Siemens' work must be considered as the forerunner of at least two well-known kinds of electric steel furnaces which are in existence to-day in actual comercial use for the manufacture of steel, although he never was able to do commercial work with his apparatus because electrical engineering was not sufficiently advanced.

The growth of the Siemens' electric furnace for steel making was at first slow for numerous practical difficulties in its working had to be overcome, but so many of these have at last been met successfully by men like Heroult Girod, Stassano and others who have modified the apparatus in various ways, that now we have furnaces like those of the Steel Corporation in Chicago and Worcester working on charges of 15 tons of steel.

Siemens in his furnace used direct current and laid particular stress on the point that the charge should be connected to the positive side of the circuit, since it is well known that in the electric arc it is at the positive electrode the main generation of heat occurs. In the modern furnaces, however, alternating currents are used for obvious reasons, and the surface of the molten bath is covered with a layer of slag which becomes intensely heated, not only by the arc but by the current which it carries. In this way ideal conditions are obtained for refining the metal as the steel and the molten slag between which chemical reaction is desired are intensely heated at their surfaces of contact. Moreover, the slag effectually prevents the introduction of carbon from the electrodes into the metal. The problem of regulating the electrodes automatically has also been successfully worked out by means of the well known Thury regulator, though it would seem that this could be simplified.

There were, of course, a large number of metallurgical problems to be worked out in connection with the steel furnace, but these have apparently been met successfully, and we finally have the electric furnace working alone commercially, or what is perhaps more generally important, acting as an auxiliary to fuel heated furnaces. The most serious problems connected with furnaces of this type at the present time are those relating to electrodes and roofs. Some years ago when the electric furnace was working on a much smaller scale than is demanded to-day, the strongest argument advanced against it was that the cost of heating by means of an electric current must of necessity be so excesive that the idea was impracticable. That, however, is criticism seldom heard to-day for it has been found that in actual practice the furnace can be so used that the question of cost of electrical energy is by no means of the first importance. On the other hand, little used to be said about electrode cost, but now that is a most vital question and is apt to enter into the total cost of working as a much larger item than power.

The manufacture of large carbon electrodes, say 20-in. (50.8 cm.) square and from 7 to 10-ft. (2.3 to 3.04 m.) long, is by no means easy, and even when they are successfully made in the electrode factory they may go to pieces in the furnace. Even if they do not break there is the problem of "butts." Suppose a large electric steel furnace with the roof three ft (0.91 m.) away from the bath, then it is safe to say that when the electrode holder is lowered down and comes in contact with the roof of the furnace, that there will be a carbon "butt" about four ft. long (1.22 m.) which must go in the scrap pile. Apparently this serious difficulty is going to be overcome by electrodes which can be fastened end to end so that they may be continuously fed into the furnace, and thus there will be no waste from "butts." Within the last few months there has been a good deal of work done in this direction and the results are very promising. The electrodes are made with a circular cross-section instead of square and have threaded sockets in the ends so that by means of threaded plugs the electrodes may be fastened together and thus fed continuously into the furnace without any waste.

This, as has been said, is promising, but has the limit of the electric steel furnace been reached as regards size? Except as regards electrodes there is no reason to believe that it has, but the 15-ton furnaces working now, need electrodes about 20 in (50.8 cm.) in diameter, and if the size is doubled and the general design is kept the same.

---

*A paper presented at the 29th Annual Convention of the American Institute of Electrical Engineers, Boston, Mass., June 25, 1912.

electrodes 27 or 28 in (68.5 or 71.1 cm.) in diameter will be required. Perhaps these can be made and can be used continuously as described above, but the writer believes that development in this direction is a mistake, and that far better results can be obtained by multiplying the number of electrodes and keeping the size within reasonable limits. This is not merely a question of avoiding the difficulties of large electrode manufacture, but involves more efficient and satisfactory working of the furnace. It will readily be seen that distribution of temperature in the furnace is bound to be better as we multiply the relatively small areas where the heat is generated, and this is an important consideration. The objection that is raised to this proposal is the difficulty of regulating the rate of generation of energy at the various electrodes. It does not seem that this difficulty is a real one.

The roof problem is altogether a different one. It must be remembered that the heating effect in the steel furnace is generated in an arc and in a resistor formed by the slag, and that consequently the surface of the slag is intensely hot, particularly where the arc strikes it. These conditions are very severe and combined with the corrosive action of the lime which is vaporized from the slag, make the roof renewals a heavy item in the cost of electric steel.

This problem has recently been the subject of careful study in two research laboratories, with one of which the writer is connected. As a result of a great deal of experimental work a brick made of silicon carbide has been manufactured which it is believed will have a much longer life in the steel furnace than the silica brick now used. The brick is made by taking powdered or granular silicon carbide, mixing it with a suitable temporary binder, such as a solution of dextrine, molding and then heating in an electric furnace to the temperature at which silicon carbide is formed. Bricks made in this way have been used in the roof of an experimental steel furnace in one of these laboratories and then put to the severest test possible. The bottom of the furnace was purposely raised well above the normal level so as to bring the surface of the slag as close to the roof as possible, the actual distance in some experiments being only 10 in. (25.4 cm.) Then the furnace was worked at double the normal rate of generation of energy so that the heating of the roof was very intense, so much so that an ordinary silica roof would melt down rapidly and be completely destroyed in a single heat. Even under these very severe conditions the silicon carbide roof stood up perfectly. Experiments have also been made in other steel furnaces and these results confirmed. The most serious objection to a roof of this kind is its relatively great cost, but if it lasts a sufficiently long time it is nevertheless economical.

Twenty-five years ago Ferranti in England and Colby in this country worked on the very interesting furnaces known as the induction type. In this the secondary of a transformer consists of the metal to be melted. As in the case of the Heroult furnace the original inventors were too far ahead of the times and it was not till 10 or more years later that any commercial application of the furnace was made. Since then the induction furnace has developed considerably and is now used with success in the manufacture of steel. An objection to the induction type is that the low power factor gives rise to certain problems, connected [illegible] which are serious where it is desired to build furnaces of large capacity. The worst of these is the very low power factor of the furnace. To overcome this objection [illegible] plant [illegible] to have a generator furnishing currents of excessively low frequency. Thus, at the Völklingen steel works a generator giving a current of 15 cycles is used, and for larger furnaces it has been proposed to use a five-cycle current. In an experimental induction furnace plant built by the writer's laboratories for an electric furnace company at Niagara Falls, the low power factor was corrected by using a synchronous motor as a condenser.

Nearly thirty years ago the Cowles brothers were working with the electric furnace in attempts to heat the charge of zinc retorts by electrical means. The principle involved in this case was mixing with the ore to be reduced a certain amount of carbon which not only acted as a reducing agent, but made the charge as a whole a conductor of the current. This furnace may be considered the forerunner of an immense number of electric furnaces in operation to-day, furnaces for making calcium carbide, the ferro alloys, iron ore smelting, graphitizing, etc. The Cowles furnace was a small one, but since its day the development of the electric furnace helped by the corresponding development of electrical apparatus has led to the construction of units of continually increasing size. To follow up the development of these furnaces would certainly trangress the limits of this paper, and instead, the development of a somewhat different type will be considered because the writer has been more intimately associated with it, and because it contains points which are, perhaps, of more particular interest to the electrical engineer.

In Acheson's first experiments which led him to the discovery of silicon carbide (carborundum) he used a furnace of the Cowles type. It consisted of a small brick box with carbon terminals at each end so arranged that they could be moved in and out in a horizontal direction. This box was then filled with the mixture of sand and coke (clay and coke in the earlier experiments) and the terminals brought together, or very close to each other, and then gadually withdawn as the furnace heated. It was soon observed that a more satisfactory way of constructing the furnace was to have stationary terminals connected to each other by means of a resistor composed of granular carbon and then surround this with the charge. With such an arrangement it was necessary to have some means by which the voltage could be regulated so as to keep the rate of generation of energy in the resistor constant throughout the run. This was found by Acheson to be a much more satisfactory way of working the silicon carbide furnace, and by experiment he found the best dimensions for his resistor. In the original small plant, where the furnaces had a capacity of about 100 kilowatts, the generator supplied current to a great bank of small transformers so that variations in the voltage could be obtained by suitable connections of the secondaries. When, however, a plant was established at Niagara Falls using furnaces of 750 kilowatts, the problem of varying the voltage at the furnace terminals became important. This was solved by the construction of a large induction regulator to be used in the secondary circuit of the transformer which stepped down the primary current of 2200 volts to 160 volts. The induction regulator then made it possible to vary the e.m.f. by 60 volts on either side of this, so that at the furnace terminals the total range was from 100 to 220 volts. For furnaces of this resistant type the induction regulator is an ideal apparatus, and it is to be regretted that it is not more generally used. The objection raised to it is usually its relatively high cost, but the convenience and simplicity of the apparatus far more than compensate for the extra cost. In working with a furnace having a carbon resistor the resistance when starting is high and, consequently, to save time it is necessary to start the furnace with a high voltage. When the resistor becomes hot its resistance progressively decreases and the voltage must then be decreased to keep the rate of generation of energy constant. If this is done in a series of steps the results are not satisfactory, for when the maximum kilowatts are reached and the voltage is lowered one step the kilowatts are decreased proportionally, and in large furnaces it is a long time before the resistance drops to the point where the desired rate of generation of energy is again reached. This is a most inefficient method of working and the consequent loss will more than pay the interest on the cost of suitable apparatus for regulating the voltage.

Even at the time when these much larger furnaces were built the theoretical conditions involved in their construction were not understood, nor indeed for long afterwards. Thus, when the Niagara furnaces were first built the dimensions of the resistors were found to be altogether wrong, and about that time, when the writer took charge of the furnace department, experiments were tried with flat resistors, though an appreciation of the theoretical conditions of the problem shows at once that, other things equal, the resistor of circular cross-section must be best.

In any furnace in which the charge surrounds a resistor heated by means of an electric current it is obvious that the important consideration is the rate of generation of energy per unit surface of the resistor. The surrounding charge, or whatever it is desired to treat, can at a definite temperature absorb heat at a definite rate. Therefore, if it is desired to preserve the charge at a definite temperature it is necessary to generate the heat only so fast as the charge will absorb it. In other words, it is necessary that the watts should be a certain definite amount per unit surface of the resistor. The knowledge of the absolute value of the temperatures in such furnaces as those used in making silicon carbide is very scant, although some excellent work is now being done on this subject; but from the data obtained experimentally and the theoretical considerations of the working of such furnaces, it is possible to calculate relative temperatures with considerable accuracy.

This was well illustrated in the experimental work done by the writer in the difficult problem of making what Acheson called "siloxicon." This substance is formed by the reduction or partial reduction of silica and is combined in some way with carbon. The great difficulty in making the material is due to the fact that at a temperature very slightly above that at which the reduction of silica by carbon begins the process goes too far and the well known crystalline silicon carbide is formed. In order to calculate the dimensions of a resistor suitable for making the material the only data available were those which could be obtained from a study of conditions in the silicon carbide furnace. Without going into details it is sufficient to say that working in this way a furnace was soon designed which made large quantities of "siloxicon" without the formation of any serious quantity of crystalline silicon carbide.

The object in devoting so much consideration to this subject is because it illustrates in a marked manner the comparative ease with which electric furnaces can be adjusted to delicate temperature conditions. This is, of course, well known as regards small laboratory furnaces, but what we are considering now is a furnace about 30-ft. (9 m.) long, 12-ft. (3.6 m.) wide and 6-ft. (1.8 m.) high, having a capacity for a charge of about 60 tons.

The greatest progress in the electric furnace since Siemens' time has been in the arc furnaces of the kinds he used; in the induction furnaces of Ferranti and Colby; and in the resistance furnace of the Cowles type; but so far as the furnace depending on the use of a heating resistor, other than the charge, is concerned there has not been any great advance as regards apparatus of large capacity. The explanation of this is found in the structural difficulties involved. It is believed, however, that those can be overcome, and, moreover, that it is well worth while spending considerable effort in this direction. In the laboratories with which the writer is connected much time has been devoted to a study of this type of furnace, and more or less successful furnaces worked out. This kind of furnace for example lends itself very readily to a form of apparatus which is bound to be developed sooner or later where the heating is accomplished by means of fuel as well as the electric current. This has been done with success in furnaces on a large scale where the preliminary heating is carried on by means of fuel until a temperature is reached where it becomes economical to use the electric current to get the higher temperatures desired. Moreover, in such furnaces we may usefully employ nearly all of the electric current by jacketing with burning gases which eliminates nearly all radiation from the interior of the furnace by supplying the inevitable heat losses from fuel rather than electricity.

The question of the loss of heat through the walls of electric furnaces is a matter that is now attracting a great deal of attention for its importance is very great. The writer has recently had occasion to give this matter careful consideration owing to the inefficient working of an electric furnace designed for some special smelting work. The testing of this furnace showed that the heat losses amounted to 50 per cent. but merely covering 25 per cent. of the outer surface of the furnace with a moderately good heat insulator reduced this loss nearly 20 per cent.

Before closing the remarks on this type of furnace it may be of interest to note some experiments recently carried out with an electric kiln at the writer's laboratories. The kiln is the invention of Mr. John L. Harper and is of the continuous channel type. Two long channels run parallel to each other and through each of these passes a train of trucks in opposite directions. The centre part of the kiln is heated electrically. With this arrangement, the trucks with their contents passing from the high temperature part of the kiln, give up their heat to the trucks going to the high temperature part. Theoretically with an arrangement of this sort all that is required of the electric energy is to supply the heat losses from the kiln. Various experimental furnaces of this kind have been built, the chief object in view being a study of the structural features of the kiln, such as the best form of resistor, refractory linings, etc., also tests of the control of temperature maximum temperature available, control of atmosphere, heat insulation, etc. The kiln was used for various purposes, but the prinicpal experiments were made on porcelain with the production of "biscuit" and glazed ware. The control of temperature was found to be very good and the kiln was extremely simple to work, requiring very little attention.

It is not pretended that in this paper the subject of the development of the electric furnace has been more than superficially treated, the attempt being simply to take a few examples which would illustrate how the electric furnace has developed and indicate some of the problems involved in its construction and working to-day. This, naturally, confined the subject to a certain extent to matters within the writer's own experience; but it is hoped that this may prove somewhat more interesting than a mere catalogue of modern furnaces compiled from the literature on the subject.

CULTURE IN THE EDUCATION OF ENGINEERS.*

By William L. Saunders.

At one of the meetings of the American Institue of Mining Engineers, held in the hall of the Sheffield Scientific School at New Haven, a discussion arose as to whether or not sufficient importance was given to cultural studies in our scientific schools. A diagram was exhibited showing graphically the relative proportion that culture bore to other studies in the various colleges. In some there was a wide distribution of cultural work, in others the proportion was small, and in a few cases it was shown that these studies were entirely omitted in the curriculum. During recess a group of students were discussing the subject; one of them, a senior, said, "I don't see why they should learn a person culture in a scientific school." This remark, made in my presence, so impressed me as a concrete example of neglect in true educational lines that it has been chosen as a text for what is to follow.

Education in its broadest sense is mental and moral training. High schools and colleges differ from common schools in that they aim at higher planes of mental and moral life. The small boy is taught by stuffing, as one puts sawdust in a doll; this is because his mind has not grown to the stage when it can think for itself. Impressions are received and transfixed by memory; the process is one of mental photography; the moral code is learned by rote as though it were the multiplication table. Not so with the older, the college student; his highest aim in education is to learn to think for himself. "If you are a student force yourself to think independently; if a teacher compel your youth to express their own minds," writes Dr. Osborn of Columbia; and again, "The lesson of Huxley's life and the result of my own experience is that productive thinking is the chief means as well as the chief end of education.

Now what is productive thinking? Let me answer this question by giving you Huxley's definition of culture: "The pursuit of any art or science with the view of its improvement." The storage process is of paramount importance only when applied to elemetary education. It is but the auxiliary of the scholar who has passed from the junior to the senior stage of student life, and who aims to do things in the world. The pursuit of facts is a mathematical study. We learn of things that exist as a result of divine and human creation. The earth is round and it is composed of land and water. Water is hydrogen and oxygen combined. The square of the hypotenuse of a right angle triangle is equal to the sum of the square of the other two sides. How important are these facts? It is important that we should know them but even a large volume of facts when stored in the human mind is powerless to add one cubit to progress. It is like putting a pair of legs on the Encyclopedia Britannica and expecting it to do something. Knowledge is power, but reason is power in action.

Mr. James Gayley of the United States Steel Corporation, recalling recently that his professor at Lafayette College who taught him how to think made so deep an impression [illegible] his life. Mr. Gayley is distinguished for what he has done as a metallurgical engineer. His life has been one of productive thinking; he has pursued science with the view of its improvement. That teacher, Mr. Gayley said, once gave him a [illegible] and instead of instructing him how to do it [illegible] told him to try three or four ways of doing it and report which was best. This led directly to thought and resason and built up a master mind among engineers. We may still heed the voice of old Carlyle crying from the heathery hills of Dunscore; "Produce! Produce! Were it but the pitifullest infinitesimal fraction of a product, produce in God's name! 'Tis the utmost thou hast in thee; out with it then."

Where among all the professions do we get the results that come through productive thinking as from engineering? The engineer is the architect of the world's progress. Transportation in railways and ships, in motor cars and aeroplanes, is the productive thinking of mechanical engineers woven into our industrial life. The men who did these things were students of science, not that they might be mere storehouses of knowledge, but that they might produce. Civil, electrical, chemical and mining engineers are fields which afford infinite opportunities for research and progress. If you men of the future do not rise to your chance in these lines it is not because the fields are not still open for cutivation and growth, but rather through your own inefficiency or perhaps your top-heaviness.

"In vain our toil,
We ought to blame the culture, not the soil."

Even Huxley feared that men might be over-fed scientifically when he said: "An exclusively scientific training will bring about a mental twist as surely as an exclusively literary training. The value of the cargo does not compensate for a ship's being out of trim; and I should be very sorry to think that a scientific college would turn out none but lop-sided men."

All this bears upon culture in its broadest sense. Productive thinking is the most important form of culture. It makes for power, refinement, progress, knowledge, taste, civilization. The subject, you see, is a very broad one; the obligation upon you as students of science is equally broad. Take care that you be not "lop-sided men." A graduate of the Colorado School of Mines, like all graduates of the higher institutions of learning, misses his opportunities and discredits his college if he does not carry throughout all his walks of life the imprint of the educated man. Noblesse oblige is a degree and an obligation which is uniformly conferred upon all college men. To carry this obligation properly one should study culutre in all its phases and in its broadest sense. Study it as an undergraduate and study it still harder and more fully through all your post-graduate life. To this end let us accept and profit by that definition of culture given us by Matthew Arnold: "Acquainting ourselves with the best that has been known and said in the world." A professor at Wellesley College defined culture to the students as that which is left after all else learned at college is forgotten.

Virtue and moral training belong to cultural work in the education of engineers. It is a mistake to suppose that schools and colleges are places for mental training only. Physical exercise through athletics is just as much a part of one's college life nowadays as the study of mathematics; the one helps the other. Emerson said, "Archery, cricket, gun and fishing rod, horse and boat, are all educators, liberalizers." To the engineer physical training is of value in order to fit him for outdoor work. Moral training is of even greater importance. Locke has placed virtue first in defining the objects of education. Wisdom he puts next, and then good breeding; last of all learning. It is more the province of the teacher than of the student to safeguard and train the character by precept and example, for, after all, "the foundation of culture, as of character, is at last the moral sentiment. This is the foundation of power."

It is a common saying that manners make the man. Good manners afford us easy weapons with which to win friends and to conquer enemies. Manners adorn the gentleman and smooth the way of the educated man through the world. Manners are never born in men; but they are bred by association and study. Like oil on the journals of an engine, they avoid friction and aid efficiency. There are many reasons why we should be polite, but the best reason is because it pays; it costs nothing. It is said of William Earl of Nassau that he won a subject from the King of Spain every time he put off his hat. So engaging were the manners of Charles Fox that Napoleon said of him on the occasion of his visit to Paris in 1805: "Mr. Fox will always hold the first place in an assembly of the Tuileries." "My gentleman," said Emerson, "will outpray saints in chapel, out-general veterans in the field and outshine all courtesy in the hall. He is good company for pirates and good with academicians; so that it is useless to fortify yourself against him; he has the private entrance to all minds, and I could as easily exclude myself as him."

---

*Address delivered at the 38th Annual Commencement, Colorado School of Mines, Golden, Colo., May 14, 1912.

Good speech is a rule of manners. It always avoids exaggeration. Moderation in language and tone is the trademark of good breeding, and good breeding is after all mainly a mater of self culture. Madame de Staël valued conversation above everything, and so engaging was she in that art that a prominent lady of France said of her: "If I were Queen I should command her to talk to me every day." The man of education mixes with the right kind of people and reads good books. Books lead us into pleasant paths of culture and happiness. Read that you may avoid worry; read that too much hard thinking may not dull the edge of intelligence and sap the roots of memory; read that you may know what has been done in the world; read that you may acquire that power which comes from knowledge; read that you may learn to value the example of great men's lives; that through them you may know that the grave is not the goal of life. Montaigne had a passion for books and never travelled without them; he said that reading roused his reason and employed his judgment rather than his memory.

But of greater importance than good speech and reading, of higher value to the engineer than manners, is ability to write good English. Engineers are not given to public speaking; they pride themselves in being workers; they compare themselves with General Grant who did things. It is very true that the engineering profession is one of practical work; but no one can hope to achieve prominence in this profession who cannot write good understandable English. An engineer may not talk, but he must make reports, he must write letters; he should draw specifications and plans. To do these things properly he must command and know how to use the tools of language. Lord Bacon tells us that "reading makes a full man, conversation a ready man and writing an exact man." Engineering is an exact science; accuracy is the one column on which the whole structure is reared. To write clearly and accurately can hardly be called an accomplishment; it is really a necessity. No college course is complete, whether it be a classical, scientific, medical or law course, without a thorough training in English. No graduate is worthy to be called an educated man who does not speak and write good English. It lifts a man above the common; it makes him bigger than his business or profession; it trims the ship of knowledge and puts oil on rough places; it makes the man.

Margaret Fuller said that the object of life is to grow, and James Freeman Clarke has written a lecture upon this subject, "Man's Duty to Grow." A post-graduate course in self-culture will tend to upward growth. Such a course is open to every one. The greatest opportunities for that education which unfolds the whole nature of man are those which are opened when we close the college door behind us. Graduation only marks the beginning of education to one whose face looks forward and upward. Let us build high; "they build too low who build beneath the stars." Build so that life and strength and growth may vitalize the whole structure; build on lines that are straight; build so that every root and branch of the tree of knowledge lends support and does not add a twist to the whole; build that men may see in you not alone skill and wisdom, but honor, culture, manhood, example; study to improve self—

"For virtue only makes our bliss below,
For all our knowledge is ourselves to know."

DRILLING 1 1/16-INCH HOLES IN ONE-INCH PLATES IN FOUR SECONDS AT THE PANAMA CANAL.

For the final riveting of the enormous lock gates at the Panama Canal the McClintic-Marshall Construction Company, of Pittsburg, has installed sixteen special electrically operated machines for drilling and reaming rivet holes. Each of these machines weighs about six tons, and is capable of doing the work of five ordinary type reamers.

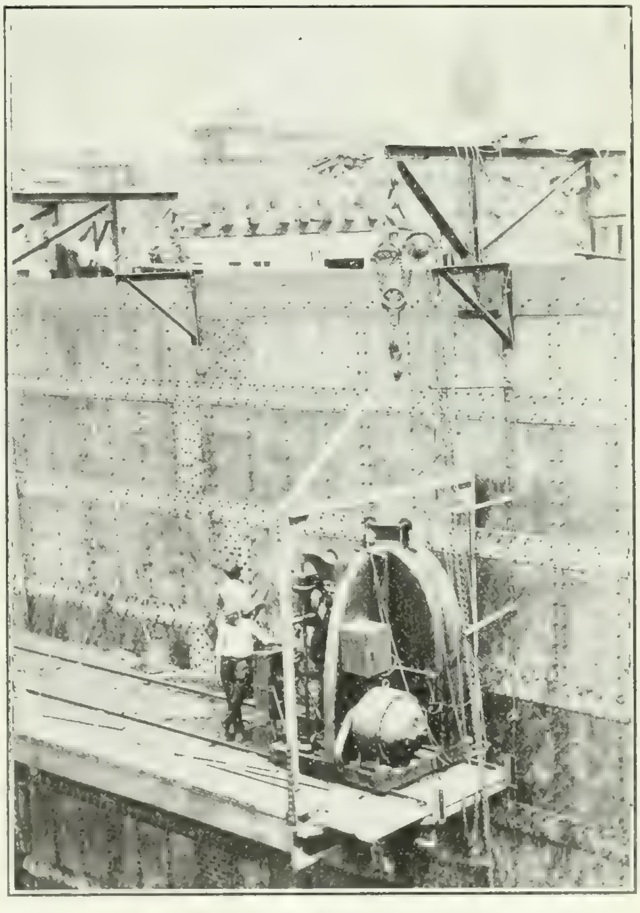

Fig. 1.

The machines are designed to run on a standard gauge track and are mounted on broad adjustable scaffolds, which are suspended from brackets by chains from the top of the gate, as shown in Fig. 1.

The inclined hand wheel shown in Fig. 2 operates through a train of gears and moves the machine along the track. The tool can readily be moved as roller bearings are used.

It will be noticed from Fig. 2 that the entire controlling mechanism is placed within easy reach of the operator. The horizontal hand wheel actuates suitable reduction gearing and a screw which raises or lowers the spindles, while the quick return motion through the spindles is actuated by means of the spider hand wheel, or by any of four levers. These levers automatically engage the quick return mechanism and enable the spindles to be run in and out.

Each machine is provided with four changes of power feed, which are instantly available through the quick-change gear mechanism. The length of the power feed is 16 inches, and the machine is so arranged that either one or both of the spindles can be fed independently.

The clutch lever for placing either spindle in operation is located on the head of the machine, while the feed changing lever is just above the clutch lever. This hand wheel is used for raising and lowering the head, which in turn is accurately counterbalanced, so that this raising and lowering is done with the least possible effort.

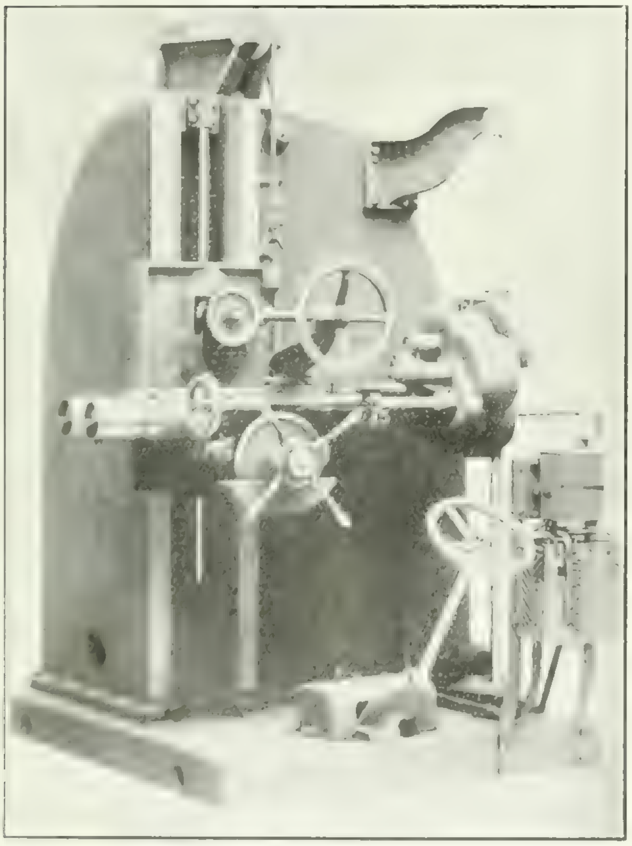

FIG. 2.

[illegible]

COSTS OF STEAM POWER PLANTS.

At the January meeting of the Engineers' Society of Western Pennsylvania some general unit construction costs of turbo-electric power plants were presented by R. W. Stovel and O. S. Lyford, Jr. These costs were based upon the maximum continuous capacity of the plant instead of on the "normal" rating. In this way the costs became comparable with those of gas-engine and hyrdo-electric installations. For coal-burning plants ranging from 2000-kw. to 20,000-kw. capacity the costs were stated to vary between the following limits:

TABLE I.—COST OF STEAM TURBO-ELECTRIC GENERATING STATIONS FROM SAY 2000-KW TO 20,000-KW CAPACITY, BASED ON MAXIMUM CONTINUOUS CAPACITY OF GENERATORS.

	Dollars per kw High.	Dollars per kw Low.
Preparing Site.—Dismantling and removing structures from site, making construction roads, tracks, etc.	$0.25	$0.00
Yard Work.—Intake and discharge flumes for condensing water, railway siding, grading, fencing sidewalks, etc.	2.50	1.00
Foundations.—Including foundations for building, stacks and machinery, together with excavation, piling, waterproofing, etc.	6.00	1.00
Building.—Including frame, walls, floors, roofs, windows and doors, coal bunker, etc., but exclusive of foundations, heating, plumbing and lighting	12.00	4.00
Boiler-room Equipment.—Including boilers, stokers, flues, stacks, feed-pumps, feed-water heater, economizers, mechanical draft and all piping and pipe covering for entire station except condenser water piping	24.00	12.00
Turbine Room Equipment.—Including steam turbines and generators, condensers with condenser auxiliaries and condensing water piping, oiling system, etc.	22.00	12.00
Electrical Switching Equipment.—Including exciters of all kinds, masonry switch structure with all switchboards, switches, instruments, etc., and all wiring except for building lighting	5.00	2.00
Service Equipment.—Such as cranes, lighting, heating, plumbing, fire protection, compressed air, furniture, permanent tools, coal and ash handling machinery, etc., etc.	5.00	2.50
Starting Up.—Labor, fuel and supplies for getting plant ready to carry useful load	1.00	0.50
General Charges.—Such as engineering, purchasing, supervision, clerical work, construction, plant and supplies, watchmen, cleaning up, etc.	6.00	3.00
Total cost of plant to owner, except land and interest during construction	$83.75	$38.00

Some of the group costs in this table do not have any very specific relation to the kilowatt capacity installed in the plant and the probable range in such costs is given. This refers to such groups as "Preparing Site," "Yard Work," "Electrical Switching Equipment" and "Service Equipment." For instance, the electrical switching equipment costs depend much more on the extent and the scope of the electrical distributing system than upon the actual capacity of the plant. Again, the largest item of the "Service Equipment" costs—namely, that of coal handling—depends upon the existing physical conditions much more than upon the capacity.

The foundation costs will run from $1.25 to $4 per square foot of building plan area, depending on the character of the soil, the lower cost covering simple concrete footings on thoroughly good bearing soil, while the necessity for piling, waterproofing, excessive rock excavation, etc., will run this cost toward the higher limit. Then the plant area will vary from 0.8 sq. ft. to 1.5 sq. ft. for each kilowatt of capacity installed, depending upon the size of the units and upon their arrangement, the combined effect of these two cost ranges giving the range in price per kilowatt shown on the table.

The building costs will vary from 8 cents to 12 cents per cubic foot of over-all building volume, according to the size of the building, the character of construction and the local price of building material and labor. Depending again upon the size of the units and upon the efficiency used in arranging them, there will be required from 50 cu. ft. to 100 cu. ft. of volume per kilowatt of capacity. The combined effect is to make the building costs range from $4 to $12 per kilowatt as shown.

In boiler room equipment the cost of material and labor will generally be between $[illegible] and $40 per nominal boiler horse-power, and generally there will be installed between 0.4 and 0.6 boiler horse-power per kilowatt of capacity, resulting in the cost range shown in the table.

It is seen that the cost of such stations under normal conditions may range in price from $40 to $85 per kilowatt of maximum continuous generator capacity. The minimum is possible only with an extremely fortunate combination of circumstances, such as natural advantages of location combined with most favorable sizes and arrangement of apparatus.

Table II. shows a probable high and low range of costs for detailed boiler room equipment. It will be noticed that the totals here shown cover a wider range than used in preparing Table I., where the price per horse-power was taken as from $30 to $40; this is because, while the wider range is possible, the costs in generating stations generally lies within the narrower range. The unit costs in this table are related to rated boiler horse-power instead of the kilowatt as used in Table I., as these costs vary almost directly with the rating of the boilers, regardless of how much boiler capacity may be installed.

Table II.—Boiler Room Equipment Costs per Rated Boiler Horse-power Using Coal for Fuel.

	Dollars per hp High.	Dollars per hp Low.
Boilers exclusive of masonry setting	$11.00	$8.00
Superheaters	3 00	0
Stokers	5.50	3.00
Masonry settings for boilers	3.50	2.00
Flues	1.50	0.75
Stacks	4.00	2.00
Economizers	4.00	0
Mechanical draft	3.00	0
Feed pumps	1.50	0.50
Feed heaters	1.00	0.40
All piping and pipe covering	10.00	6.00
Coal chutes and ash hoppers	1.25	0
Various, such as indicating and recording devices, damper regulator, ladders and runways, painting, etc., etc.	1.00	0.50
Total	$50.25	$23.15

Note—The above costs are for labor and material only. They do not include any "general charges" such as engineering or supervision. The piping item includes all piping in the entire plant except condenser water piping.

Table III. indicates generally the range of ordinary operating results. Coal of 14,000 b.t.u. per pound is assumed in both cases for convenience.

Table III.—Summary of Operating Results.

	Range of Common Practice.	
British thermal units per pound of fuel	14,000	
Average yearly over-all boiler and furnace efficiency	50	70
Effective British thermal units per pound of fuel	7,000	9,800
Boiler pressure, pounds per square inch, gage	125	190
Superheat, degrees Fahr	0	125
Average feed-water temperature, degrees Fahr	120	200
British thermal units per pound of steam (approximate)	1,100	1,100
Pounds of water evaporated per pound of fuel, actual	6.36	8.91
Pounds of fuel per standard boiler hp (33,305 b.t.u.'s)	4.76	3.40
Average over-all station water rate kw	30	20
Pounds of coal per kw generated	4.72	2.25
British thermal units in coal per kw generated	66,000	31,500
Thermal efficiency of station	5.2%	10.8%

◆

INCREASED USE OF WATER-POWER.

Of the 30,000,000 horse-power used in industrial and public-utility enterprises in the United States, reports the Commissioner of Corporations, 6,000,000 horse-power is now developed by water. At a conservative estimate, this saves 33,000,000 tons of coal per year. Several million more horse-power could profitably be developed from the same inexhaustible source.

Of the 6,000,000 horse-power now developed, 3,270,755 is generated for sale (that is, not for private use, as in manufacturing) by companies or groups of interests having 50,000 horse-power or more actually developed or under construction. The report concludes that it is not feasible to regulate the price of water power by itself but rather to control the sites, or their uses.

TO WHAT DEGREE MUST SEWAGE BE PURIFIED?*

By Chester G. Wigley, of the Division of Sewerage and Water Supplies, State Board of Health, New Jersey.

The economic disposal of sewage resolves itself into a problem of deciding what degree of purification is to be obtained and this degree of purity should depend primarily upon the size and character of the body of water into which the effluent is to be discharged. It too frequently happens that the effluents from disposal plants are not of acceptable quality and this condition can often be traced directly to inefficient supervision over the operation of the works. If a political officeseeker, without knowledge of the requirements of sanitary engineering, be placed in charge of the plant, there is small chance of securing satisfactory results.

Sometimes it has happened that engineers after designing and constructing a sewage disposal plant depart without leaving any directions for its proper maintenance. This has sometimes resulted in a rapid deterioration of the plant and a consequent loss to the municipality. It is for this reason that one of the chief functions of a board of health or sewerage commission is to see that the disposal plants are operated in a satisfactory manner. This is one of the most difficult phases of the sewage disposal question to-day, especially in connection with small installations.

In the design of any disposal plant there are two questions of economy. The first deals with the relative economy of the various types of any of the units comprising the plant, for example, the relative advantages of various types of settling tanks, and the second to a consideration of the general public welfare and the interrelations of groups of municipalities situated upon the same body of water. It is these latter relations which are directly affected by the limitations of the degree of purification of sewage and the most economic method of disposal is the one in which the best relations may be maintained at the smallest cost. It would appear that we are fast approaching, if we have not already reached the point, at which the large quantity of sewage from populous districts is compelling a bacterial standard of efficiency rather than one of sight and odor.

We may first consider the disposal of sewage with reference to the waters, according to their geographical classifications, such as the ocean, bays, rivers, brooks and lakes. Any system of disposal must be viewed from the several sanitary standpoints of liability of infection, creation of nuisances, and the effect upon the environment.

It is generally conceded that the purification of sewage discharged into the ocean shall be of a rudimentary nature. This is so because the ocean is so large that it requires a large amount of sewage to cause even a local nuisance. Another reason tending to make elaborate disposal plants unnecessary is that the salt water appears to have the power of more readily oxidizing organic matter than does fresh water. Where surf bathing is a pecuniary asset it is necessary to remove from the sewage floating grease, garbage and fecal matter by screening or sedimentation and discharge the effluent at a distance from shore sufficent to prevent its immediate return. Where bathing does not enter into the problem, sewage may be satisfactorily taken care of by discharging into the ocean at some distance from shore and below the surface of the water.

In the case of a bay or sound the degree of purification demanded is higher than in the case of an ocean outfall.

---

* Abstract of paper read before American Waterworks Association at thirty-second annual convention, Louisville, Ky., June 3-8, 1912.

Here the protection of the shellfish from contamination sometimes must be provided for. The currents in the bay will ordinarily be less strong and because of its land-locked nature the sewage is discharged into a more or less restricted volume of water in which it is carried back and forth by oscillating tides. In most cases, where shellfish are not present, rough screening and sedimentation, or possibly very fine screening will be satisfactory if the effluent is discharged at some distance from the shore and the outlet at all times submerged.

In the case of rivers disposal by dilution sometimes may be adopted advantageously, but an important point to keep in mind is that the outfall should be designed to diffuse the sewage in deep running water and not to discharge it at a single point near the shore line.

Some people claim that it would be cheaper to allow a water purification plant, which should be installed in most cases where the supply is taken from a river subject to pollution, to take care of the additional burdens caused by the sewage. It is difficult to see why the burden should be shifted from the sewage disposal works to the water filters. The only place in which such a procedure would be permissible is where the quantity of sewage to be purified would cost considerably more than to purify a comparatively smaller amount of water. While this would be strictly an economic arrangement there are several things that would argue against such a practice.

The chief of these objections is this: Water purification plants are not perfect. They will at certain times fail to produce a satisfactory effluent, especially with filters of th[illegible] mechanical type. Those who advocate the purification of water instead of the purification of sewage are not allowing a large enough factor of safety. The failure of the Schmutzdecke, the entrance of wash-water into the clear water, failure in the supply of alum, soda or hypochlorite are all apt to occur and then the barriers are down. Would it not be better to relieve the burden of the water purification plant as much as possible and wherever possible destroy the pathogenic bacteria in sewage? Would it do any harm to have a factor of safety of two and purify both the sewage and water? Then in the event of the failure of one plant the consequent results would not be as bad as though all the burden were placed on one installation.

With respect to rivers, then, we may conclude that where [illegible] greatly reduce the number of pathogenic bacteria would be [illegible] simply the settling and sterilization of the sewage or its purification by settling tanks, sprinkling filters and disinfection. The latter method would only be neces[illegible] portion to the flow of the river.

[illegible]

SALE OF QUEBEC WATER-POWERS.

The announcement was made some time ago that henceforth no more water-powers would be sold in the province of Quebec. On the other hand, it will be the policy of the government to lease the water-powers for a term of years at a fixed annual rental. Accordingly, for some time past the Provincial Government has been advertising the lease, by auction, of some fifteen water-powers, for a term of seventy-five years. A number of these were disposed of at the Parliament Buildings at Quebec on June 26th. Just before the bidding, three of the powers were withdrawn, leaving twelve to be competed for. Of these, apparently only four were wanted, that, at any rate, being the number taken. These were as follows:—

At $51 per annum, power on the Assemetquagon River, near Metapedia River, Bonaventure Co., leased by James Hall, New Carlisle, in trust.

At $53 per annum, Riviere des Aux Nortes, in Hackett township, Champlain county, by Charles LeBrun, of Shawinigan.

At $3,800 per annum, Chute de la Martine, Metabetchuan River, Lake St. John county, by Herbert Moisan, of Quebec.

At $1,001 per annum, Riviere aux Outardes, Saguenay county, by St. Lawrence Industrial Company.

It is not stated what amount of power can be developed on the different falls, so that the work of making comparisons between the different leases is impossible. However, the very fact that the government will get over $5,000 per annum out of the four leases which formerly would quite possibly be given away free, is most encouraging from the standpoint of public interest, and the knowledge that all the powers of Quebec will in future be treated in this manner is very gratifying.

◆

THE C.N.R. TRANSCONTINENTAL LINE.

The Canadian Northern Railway's transcontinental line will positively be ready in 1914.

The C.N.R. tunnel under Mount Royal will be ready in two years' time, about.

Montreal, Toronto, Ottawa and other important points will be linked up by the C.N.R. line this year.

The C.N.R. has just obtained the money to complete its transcontinental line.

These are some of the statements made by Sir William Mackenzie while in Montreal en route to England. It was the common thought among financial circles that Sir William was going to England for the purpose of obtaining additional capital for carrying out the projects of the Canadian Northern Railway, and it is still thought that this actually is the case, although the president of the company states the company has just obtained the money to complete the line. It is assumed that he does not refer to the cost of constructing the tunnel under Mount Royal and various other schemes more or less essential to the completion of the C.N.R. Transcontinental line.

It was the general idea in Montreal that the C.N.R. hoped to be able to build the tunnel out of the profits reaped in the rise of land values at the northern portal of the tunnel, a large area of which the company purchased as farm land before announcing its project, and the bulk of which has probably since been sold as building lots at prices ranging to upward of $1 per square foot. In any case, Sir William intimates that he may have something of importance to announce upon his return.

THE LATE CECIL B. SMITH.

By the death of Cecil B. Smith the country has lost one of its most successful and brilliant engineers. Mr. Smith was one of the first of a new type of consulting engineer to enter the professional field in Canada. Many of the older men of the profession were men educated under the pupilage system who obtained their knowledge of engineering through practical experience. This class are steadily becoming in the minority, the newer class being men trained in the technical colleges before taking up practical engineering. Mr. Smith was one of the first of the college-trained men to enter the consulting field in Canada. He was educated at McGill University, and, after having obtained considerable experience, was appointed assistant Professor of Civil Engineering there. As a man Mr. Smith was well liked by everyone. The younger men of the profession, who at different times have been employed under his direction, have always parted from him with the greatest liking for his personality and with the highest respect for his ability. As an engineer he ranked with the leaders of the profession on the continent. The work which will probably be remembered most to his credit was that which he did as chairman of the Temiskaming and Northern Ontario Railway Commission and as Chief Engineer of the Ontario Hydro-Electric Commission in its early days.

THE INTERNATIONAL GEOLOGICAL CONGRESS.

The programme of the twelfth International Geological Congress, which is to be held in Canada in 1913, will be found in this issue of *The Canadian Engineer*. This Congress is of great interest to Canadians in general. The value of the annual mineral output of Canada has steadily increased year by year for the last thirty years, and is now over one hundred million dollars. Considering, however, the known resources and the enormous territory whose resources are unknown, this output is small, and Canada needs more men and more money for prospecting, development and operation. This she can best secure by attracting, not the general public, but those people whose business it is to engage in such industries and who understand their management. Geologists and mining engineers are obviously those best able to influence opinion in their own countries on the subject in which they are recognized authorities; hence the opportunity afforded by the meeting in Canada of so many eminent specialists should not be neglected. Every effort should be made to show to the world that, while our known mineral resources are large, we have an immense undeveloped territory awaiting the advent of the trained prospector. Meetings of various geological and other scientific societies have been held in Canada in the past, but this is the first occasion on which the International Geological Congress has met here, and the opportunity will not occur again for many years, since the meetings are held triennially in the different countries of the world.

Canadian geologists are fully alive to the high honor paid them and their country by the selection of Canada for the meeting, and they are being generously assisted in preparing for it by the Dominion and Provincial Governments and by the railway and mining corporations, as well as by individual business and professional men, all of whom are contributing liberally both money and time.

THE INTERNAL COMBUSTION ENGINE AND THE GAS PRODUCER.

There has been considerable discussion recently concerning the longevity of the coal fields of the country. With the increasing depletion of the coal deposits there has been a momentum given to hydro-electric installations, and an increasing demand for information concerning the possibilities of power from the internal combustion engine and the gas producer. Only last week we noted in *The Canadian Engineer* that the Province of Saskatchewan had appointed a consulting engineer to make an exhaustive report on the lignite deposits of that Province and their power-producing possibilities. The United States Bureau of Mines has been conducting investigations into the possibility of generating producer gas for power purposes in a commercial way from the various mineral fuels of the country. These investigations have been associated with steaming, briquetting, coking, and other tests, all of which supplemented an examination into the nature, extent, and distribution of the fuels used. The tests have been made with carefully selected representative samples and carload lots of coal, lignite, etc., procured especially for the purpose by experienced collectors.

The investigations have shown the adaptability of the gas producer for the utilization of low-grade coal, lignite, peat, etc, As mined, these fuels cannot be used in boiler furnaces and will not bear long transportation, but the gas producer makes them of potential value. Where deposits of low-grade coal, lignite, and peat are found, the present cost of power, as developed in steam plants with coal that has been shipped a considerable distance, can be materially reduced by placing producer plants at the mines or bogs so as to utilize these low-grade fuels without cost of shipment by generating electric current, which can be easily transmitted to desired points within a wide radius.

The tests in the gas producer have shown that many fuels of so low grade as to be practically valueless for steaming purposes, such as slack coal, bone coal, and lignite, may be economically converted into producer gas, and may thus generate sufficient power to render them of high commercial value.

It is estimated that on an average each coal tested in the producer-gas plant developed two and one-half times the power that it would develop in the ordinary steam-boiler plant. Investigations into the waste of coal in mining have shown that it probably aggregates 250,000,000 to 300,000,000 tons yearly, of which at least one-half might be saved. It has been demonstrated that the low-grade coals, high in sulphur and ash, now left underground, can be used economically in the gas producer for the ultimate production of power, heat, and light, and should, therefore, be mined at the same time as the high-grade coal. The investigations also show that the general use of gas producers for the development of power means the elimination practically of the smoke nuisance. This result is especially important in cities that are compelled to use bituminous coals. The great saving in fuel obtained through the gas producer has led to the installation within the last decade of several hundred of these power plants throughout the country. These producer plants are practically smokeless during operation. The establishment of producer-gas plants at the mines and the distribution of electric energy, or gas over large areas will also tend to eliminate smoke. When a large percentage of the small, isolated power and heating plants and all steam locomotives have been removed from the larger cities, the atmosphere of these cities will be much clearer and heavy financial losses directly traceable to smoke will be eliminated.

EDITORIAL COMMENT.

We are publishing in this issue the first of a series of articles on band conveyors. The importance of the use of conveying machinery in connection with engineering work has increased to such an extent that we feel the publication of such a series should be of considerable interest to our readers.

* * * *

The new Commissioner of Works at Toronto appears to have grasped conditions in connection with the Waterworks Department. He has just recommended that a new position be created, that of mechanical and electrical engineer of the Waterworks Branch of the Works Department. There is little question that if the right man is obtained for the position, great economies will be effected in the Department. The operation of the waterworks is one which demands a knowledge which only a mechanical man of considerable experience can furnish, and we feel sure that a much higher standard of efficiency will obtain under the new condition.

GENERAL NOTES.

Precipitation was deficient throughout Canada except very locally in the Central Valleys of British Columbia, and in southern parts of Vancouver Osland and the lower mainland, where the normal amount was slightly exceeded; also very locally in Alberta, especially in the neighborhood of Calgary, where the fall was considerably more than usual. The deficiency was particularly pronounced in Manitoba, where the fall was only a very small percentage of the normal.

The table shows for fifteen stations, included in the report of the Meteorological Office, Toronto, the total precipitation of these stations for June, 1912:

	Depth in inches.	Departure from the average of twenty years.
Calgary, Alta.	4.3	+1.03
Edmonton, Alta	3.0	—0.41
Swift Current, Sask.	2.8	—0.25
Winnipeg, Man.	0.9	—2.54
Port Stanley, Ont.	1.3	—1.41
Toronto, Ont.	1.75	—1.04
Parry Sound, Ont.	1.7	—1.26
Ottawa, Ont.	0.8	—2.95
Kingston, Ont	1.1	—2.1
Montreal, Que	1.6	—2.42
Quebec, Que.	3.1	—1.2
Chatham, N B	2.3	—0.73
Halifax, N.S.	2.6	—1.3
Victoria, B.C.	1.0	+0.04
Kamloops, B.C.	1.5	+0.22

PERSONALS.

DR. W. E. GEORGE, of Haileybury, has been appointed medical health officer for the eastern section of Northern Ontario.

MR. B. RIPLEY, A.M. Can. Soc. C.E., A.M. Am. Soc. C.E., who for the past two years has been in charge of bridge construction and renewals on the Dominion Atlantic Railway, has been appointed engineer of grade separation for the Canadian Pacific Railway at Toronto.

LETTERS TO THE EDITOR.

CONCRETING IN COLD WEATHER.

Sir,—While looking over the titles to articles in the last half year of *The Canadian Engineer* I noticed one entitled "First Reinforced Concrete in Cold Weather." As the laying of concrete in cold weather is probably an interesting subject to many engineers and contractors in Canada, I might say that the Ambursen Hydraulic Construction Company were engaged all last winter in the construction of a dam across a river called the "Magpie," in Michipicoten district, Ontario, and that concrete was laid, and perfectly taken care of there in weather of the severest description, temperatures of 30 deg. to 50 deg. below zero being common during the nights.

An Ambursen type dam is a reinforced concrete hollow dam, consisting of a number of buttresses, in this particular case 14 in. to 18 in. thick, 60 ft. long at the bottom and 36 feet high, and spaced 12 ft. centres, upon the sloping front of which buttresses a deck slab 30 in. to 21 in. thick is poured. This deck slab, resting on the buttresses, of course holds back the waters, the space between buttresses and under the deck being hollow.

Rock for the concrete was crushed in a crusher and ran from the crusher mouth into a large timber bin, on the floor of which was laid a grillage of steam pipes, pipes being about three feet centres up and down the sloped floor of the bin. The pipes were drilled with ¼-in. holes at close intervals, and the steam escaping from these holes heated up the rock in the storage bin. Sand was similarly treated or heated in an adjoining bin.

The material was run from these bins in a car to the mixer house, some distance away. In the mixer house, directly above the mixer, a water tank, holding about 10 or 12 barrels of water, was built. A steam pipe from the mixer boiler heated this water to a high temperature. Of course the water pipes from the pump at the river to the tank were protected from the frost, being laid in a box of manure with a steam line running beside the water line in the manure box.

The sand, cement and water were all, therefore, heated before entering the mixer; the concrete coming out of the mixer being generally steaming hot.

Concrete was only poured when the sun was up during the day as a precaution against being frozen before it was taken care of in the forms.

The forms were ordinary forms, built of 1-in. lumber in panels 12 ft. high and 6 ft. wide. The forms for two buttresses, 12-ft. centres, were set up and braced together. A car running along the top of these buttresses dumped the concrete into the forms. When the two buttresses were poured, which generally meant a five-hour run, a large tarpaulin was hauled across the top and let drop over the sides and ends, completely covering in the buttresses newly poured. In the space between the two buttresses several large Peterborough "lumberman" stoves fed with cord wood were kept going all night and heated the space enclosed by the canvas with such success that on several occasions, after nights during which the temperature was as low as 40 deg. below zero, forms were taken off 24 hours after the 18-inch concrete walls were poured. Of course the use of stoves necessitated cutting stove pipe holes in the canvas roof. This might probably be done away with and the canvas roof probably better preserved by the use of salamanders, using coke instead of the clumsier heavy stoves and stovepipes.

"READER."

RE PONTE DEL RISORGIMENTO.

Sir,—I have read with great interest the historical sketch on the evolution of the building of reinforced concrete arch bridges given in your issue of June 27th by Mr. H. G. Tyrrell and his remarks on the new Tiber River bridge, about which I have given a description in the same number.

There is, however, one point to which I would like to take exception. Mr. Tyrrell writes namely: "In the new Tiber River bridge with curved arch slab without hinges, rigidly connected to seven vertical ribs, it would seem that the stress condition was indefinite and the amount of thrust taken by the vertical ribs indeterminate.

I do not think that many engineers, with experience in reinforced concrete arch bridges and the use of the elastic theory would agree with that. As far as I know there has not yet been a single one of the numerous bridges figured out in that way that has shown any considerable disagreement between the calculated stresses and deflections and those actually measured on the bridge by test loads.

The circumstance that the cross section of the Tiber bridge is an inverted T does not introduce in itself any special difficulties to figuring out the forces in the slab and in the ribs. The bridge being fixed at its ends, there are three quantities which must be determined by the equations of elasticity. Maxwell's rule has very materially simplified those equations and by the choice of a special point at which we let these three quantities act we get the following practical equations:

$$X_a = \frac{\delta ma}{\delta aa}$$

$$X_b = \frac{\delta mb}{\delta bb}$$

$$X_c = \frac{\delta mc}{\delta cc}$$

X_a, X_b, X_c. mean the unknown qualities, δma, δmb and δmc are the deflections at the various points m of the main system for forces 1 acting in the direction of X_a, X_b and X_c respectively.

Whatever deflections are to be found by calculations or graphically (Villiots method) the proper moment of inertia for each section has to be used and thus the acting bending moments, normal and transversal forces can easily be found and thereafter the stresses in the steel and concrete in the sections.

V. J. ELMONT, C.E.

* * * *

Sir,—Replying to the comments of Mr. V. J. Elmont, on my report concerning the Ponte del Risorgimento over the Tiber River at Rome, it is very doubtful if any practical benefit is derived from the use of the elastic theory for computing stresses in masonry arches. The Romans used no such theory, and yet their bridges as far as endurance is concerned are far superior to many that are being built in recent years, proportioned perhaps by the elastic theory or some other equally gratifying to mathematicians, though of no greater use.

Sonstructive forms in which stress conditions are uncertain have been well exploited during the past 60 years since Mr. Whipple first published his methods of computing bridge stresses in 1847, and as far as economy of material is concerned, such forms are often quite economical, but experience has shown that conditions of uncertain stress are undesirable and such forms are now avoided by conservative designers. Many types, such as trusses with multiple web systems, or combinations of truss and arch, unquestionably have some points of merit, but because of their indefinite action they have gradually been discarded and other uncertain forms will doubtless follow in the same course. "Simplicity" is a fundamental principle of bridge design which should not be violated.

The latest Tiber River bridge is unquestionably a fine structure, reflecting great credit on its engineers and originators, but the unfortunate practice of competitive designing too often reduces the dimensions and strength almost to the danger point. Limitations in money appropriation and time, are also responsible in many cases for slender proportions, and the absence of features which might otherwise be most appropriate.

H. G. TYRRELL.

◆

PIG IRON AND STEEL

An increase of 5.58 per cent. is shown in the production of pig iron in Canada in 1910 over the production of 1909, as compared with an increase of 20 per cent. in 1909 over that of 1908, according to the report of the Department of Mines, Ottawa.

At the close of the year Canada had seventeen completed furnaces and two under construction, grouped in ten separate plants and operated by eight separate companies or corporations.

The total production in 1910 was 800,797 short tons (714,998 long tons), valued at approximately $11,245,622; as compared with 757,162 short tons (676,038 long tons), valued at $9,581,864, in 1909, and 630,835 short tons (563,246 long tons), valued at $8,111,194, in 1908. The Londonderry furnace was not in operation during either of the past two years. These figures do not include the output from electric furnaces making ferro-products which are situated at Welland and Sault Ste. Marie, Ont., and Buckingham, Que. Ferro-silicon was made at Welland during 1910, but the Sault Ste. Marie and Buckingham plants were not in operation during the year.

Of the total output of pig iron in 1910, 17,164 tons, valued at $333,956, or $19.78 per short ton, were made with charcoal as fuel, and 783,633 tons, valued at $10,911,674, or $13.92 per ton, with coke. The amount of charcoal iron made in 1909 was 17,003 tons, and in 1908, 6,709 tons; while the quantity made with coke in 1909 was 740,159 tons and in 1908, 624,126 tons.

The classification of the production in 1910 according to the purpose for which it was intended was as follows: Bessemer 219,492 tons, basic 425,400 tons, foundry (including miscellaneous) [illegible] tons.

The classification of the production in 1909 was: Bessemer [illegible] tons, basic [illegible] tons, foundry (including miscellaneous) 116,307 tons.

The American Iron and Steel Association reported the production of Bessemer pig iron in 1908 as 126,348 short tons, as against [illegible] tons in [illegible], and the production of basic pig iron in 1908 as 375,659 short tons, as against 382,208 tons in [illegible].

In Nova Scotia a large proportion of the pig iron is directly converted to steel, and as a very small portion of the metal [illegible] pig iron it is [illegible] difficult to place a satisfactory [illegible] upon the output. For statistical purposes a value of [illegible] placed upon the production in 1910. The Quebec production is entirely charcoal iron, which has for [illegible].

[illegible] prices of pig iron in Canada during 1910, a firm of iron merchants in Montreal gives the following information: [illegible] etc.; nevertheless it may be said that good average brands of Scotch iron sold in Montreal during the first three months of 1910 at about $20 per gross ton. Later in the year, particularly after the opening of navigation, prices eased up somewhat and an average price would be $19.50 per gross ton. On the other hand good foundry iron of English manufacture could have been purchased during the early part of 1910 at $18 per gross ton, then shading down to $17.25 per gross ton during the summer months. There was little competition from Canadian made iron in the Montreal district during 1910, the Sydney furnaces not marketing anything there during that period.

In Toronto the situation was somewhat different. It costs approximately $2 per ton more to lay down Scotch and English iron at that point than it does in Montreal, and during the early part of the year such advance in price was obtained. Later in the year, however, the Amreican situation seriously affected prices in Ontario, and United States pig iron competed very keenly in the Toronto-Hamilton district, practically cutting out Scotch and English iron and compellng the local furnaces to reduce their prices to an equivalent of $18.50 and down to $18, f.o.b. cars Toronto, for good average grades of foundry iron.

In Pittsburgh, Bessemer iron was quoted at $19 per gross ton in January, 1910, falling to $17.50 in March, $17 in May, $15.75 in June, and $15 from the latter part of August to the close of the year. Basic iron ruled from $1.75 to $2 per ton less.

Previous to 1896 pig iron was made entirely from Canadian ore. Since that date, however, increasing quantities of imported ore have been used as well as imported fuels and fluxes, and in 1910 about 89 per cent. of the ore charged, 49 per cent. of the coke, and 18 per cent. of the limestone, were imported. This condition is due largely to questions of cost and transportation affecting each furnace. The Newfoundland iron ores can be cheaply and conveniently laid down in Sydney, N.S.; in fact the iron industry here has been built up on the basis of these ores and of the local coal supplies. In Ontario, also, large quantities of imported ores are used. In 1910 the imported ores used in Ontario amounted to 681,918 tons and the Canadian ores 143,283 tons, the imported ores being derived from Michigan and Minnesota deposits; thus during 1910 about 83 per cent. of the ore used in the province was imported, as compared with 71 per cent. in 1909, and about 67 per cent. in 1908. The fuel used in Ontario was also almost altogether imported as well as a portion of the limestone flux.

According to returns made to the Department of Trade and Commerce in connection with claims for bounty, 84,759 tons only of the total pig iron production in Canada in 1910 were credited to Canadian ore and 659,891 tons to imported ore and bounty paid upon it as such. In 1909 bounty was paid upon 126,298 tons of pig iron from Canadian ore, and 607,718 tons from imported ore. No bounty is paid on the iron credited to the mill cinder, scale, etc., charged, so that the above figures do not represent the total output of the furnaces.

There has been comparatively little pig iron exported from Canada. During 1910, the exports were 9,763 tons, valued at $296,310, or an average value per ton of $30.35. The exports during 1909 were 5,063 tons, valued at $186,778, an average of $36.89; while during 1908 the exports were 290 tons, valued at $10,614, an average of $42.45 per ton. These exports probably include ferro-silicon as well as ordinary pig iron.

Considerable quantities of pig iron are annually imported into Canada. During 1910, the imports of ordinary pig iron were 227,753 tons, valued at $3,122,695, an average of $13.71 per ton, and of charcoal pig iron 16,106 tons, valued at $242,[illegible], an average of [illegible] per ton, or a total importation of 243,859 tons, valued at $3,364,847. During 1909 the imports were: ordinary pig iron, 147,925 tons, valued at $1,798,172, and charcoal pig iron, 413 tons valued at $5,727; and 1908, the imports were: ordinary pig iron 57,343 tons, valued at $771,715, and charcoal iron 1,022 tons, valued at $18,818. The rate of general tariff on pig iron is [illegible] per ton.

THE CONSTRUCTION OF DISTRIBUTION SYSTEMS FOR OUTLYING SYSTEMS AND SMALLER PLANTS.*

By S. Bingham Hood.

Toronto Electric Light Company.

In establishing an electricity supply service in small villages, or the more or less scattered population surrounding our larger cities, the problem becomes much more complex, both commercially and electrically, than that of the supply within the city itself. Most of the earlier small systems were constructed in a crude makeshift manner and gave at best anything but what we class to-day as reliable service. The men who financed these small plants seldom had any electrical knowledge and frequently operated the systems as a side line to their regular business—the power plant being located in some local mill or factory with the idea, generally, of using the prime mover for factory operation during the day and making it work overtime to earn its salt by driving a small generator at night. The operator of the plant, a local jack of all trades, attended to inside wiring, did the construction work on the lines; installed, read and repaired the meters (unless it was a flat rate proposition), and in his spare time operated the plant. The natural result was generally that, where the system was growing he had no time to attend to operating duties and the service became unreliable in proportion to its prosperity—at least until such time as the unreliability overshadowed the prosperity and the whole undertaking went on the rocks. This was the favorite time for the big fish to swallow the little one and has resulted quite generally in the present-day suburban systems being owned and operated by the large system of the nearest city, the local plant under these conditions being abandoned and supply obtained from the large central station.

The result of this has been of great benefit to the local suburban community, in that they not only obtain the primary supply from a modern station giving the highest class of service, both as to reliability and efficiency, but also have at their command a skilled, specialized force to design and supervise the local distribution and operation.

To successfully and profitably operate a large scattered suburban load the construction of the distribution system must be the very best that can possibly be obtained, in order that an uninterrupted service may be given. This requirement is even more imperative than within the larger community, as the suburban system must to a considerable extent be automatic in its operation owing to the difficulty, time, and expense, necessary to restore interrupted service due to line failure at points remote from the operating headquarters. Combined with this requirement the annual overhead charges must be kept as low as possible in order to make the distribution profitable. These annual charges reach a minimum where the design and construction of the distribution system is such that a maximum life is obtained with a minimum capital expenditure. Failure to realize this point was the downfall of the early systems where every effort was made to "make it cheap," with the result that the life of the system was limited to but a few years. At just what point maximum efficiency results is hard to determine. Local conditions may make a design adapted to one locality an expensive one for another. The best materials may be selected to cover the mechanical construction, but an electrical system may be adopted which may be so expensive that the combined cost becomes prohibitive. Generally speaking, however, maximum economy has been reached where the interest charges equal the ones for depreciation. In other words, the cheaper you can get your money the more you can afford to spend to lengthen the life of the distribution system.

In addition to this the first cost of current plays an important part. In water-power plants or large turbine steam plants the cost of current at the bus bars is very low, and, consequently, the line losses in transmission may be made somewhat high to advantage, particularly in suburban work where the load factor is generally low. Right here, however, a word of caution is opportune. You can make your line losses between the source of current and the point where first load is taken off anything within reason; but between the nearest and furthest load your total drop in pressure, including both primary and secondary, as well as transformer drop, must not exceed five per cent. if you expect to give service in its true sense. You can't operate a feeder with a drop if anywheres from ten to twenty-five per cent. and start loading it at the city limits and leave off at Farmer Jones' half a mile beyond the next village. We all know this, but still seem to keep on trying, with results similar to our railway friends with their efforts to eventually make a single track line operate successfully without sidings.

If we analyze the cost of suburban transmission we find that the pole line (such systems being nearly always overhead) represents the greatest proportionate investment. We also find that this portion also has to carry the larger share of the depreciation, due to its limited life under ordinary conditions. We, therefore, intend to take up first of all this part of the work and endeavor to show where maximum economy can be obtained. In suburban and semi-suburban work a thirty-foot pole line is amply high enough where the run is free of trees or other obstructions. Special cases will, of course, require higher poles, but the average condition is covered by the sizes shown in table 1. The prices here apply to average conditions of labor and material costs in the vicinity of our larger cities.

The cost of pole in the rough is that of good clear B.C. cedar, with an increase in diameter of one inch for every ten feet. The cost of shaving, framing and treating covers shaving from ground line to roof, taper or wedge roofing, cutting and boring of gains and boring for steps and sockets. The treating, where same is included, consists of a double immersion of the butt, to one foot above ground line, in carbolinum oil. First immersion to be in hot oil and second in cold.

Painting is for one coat, in pole yard, of entire pole above ground line. This coat preferably to be of a light body paint or stain, such as shingle stain, which will penetrate into the surface for an appreciable distance. The object of painting is primarily to improve the appearance of the pole, as any pole line is objectionable from the public's standpoint and anything which renders it less so is a first-investment. In addition a coat of stain undoubtedly does act as a preservative to a considerable extent. The object of stepping and socketing the pole is also to prevent its being cut up by continual climbing with spurs, which not only spoils the appearance of the line, but leaves countless little holes or pockets to collect water and drain it right into the heart of the wood of the pole. Steps are, or should be, standard ⅝-in. by 9-in. hot galvanized and have a life far beyond that of the pole in which they are to be used. The best form of socket is a malleable iron or wrought iron thimble which will drive into a ⅞-in. hole. The hole in thimble will take a ½-in. lag screw or pin which is slipped in by the lineman when about to climb a pole, and taken out when he comes down. Four of these sockets are required for each pole, making the first step come seven feet from the ground. As the sockets are not readily removable after once driven, their life is, of course, that of the pole into which they are placed.

---

* Abstract of paper presented at the Twenty-second Annual Convention of the Canadian Electrical Association, Ottawa, June 19-21, 1912.

The cost of setting given in the table is that for average digging in hard clay or loam. This column for items 9 to 14 is original cost of setting plus the cost of cutting off, digging out old butt, and dropping down and retamping the balance of pole.

The life of pole is taken as that point where the butt rot at ground line has decreased the sound diameter to that of the top of pole. This life varies widely with different conditions of soil, climate, etc., but figures given represent a fair average. For treated pole the life is uncertain owing to lack of definite data. The writer has taken the increased life as being five years for a pole with 7-inch top, as poles so treated have been under observation for this length of time and some are starting to show signs of decay, while others are as good as the day they went into the ground. Where this decay has started there is no means of telling whether it is going to be the same as an untreated pole, or faster or slower. Five years increased life is, therefore, taken as the known increase.

No.	Size and Kind	Cost in Rough	Shaving Framing Treating	Hauling	Painting and Stepping	Setting	Total	Life (Years)	Annual Cost
1	30-6 Plain	$3.06	$1.10	$0.45	$1.36	$3.50	$9.47	6	$2.05
2	30-6 Treated	3.06	2.20	.45	1.35	3.50	10.56	11	1.49

* Every 5 Years

Table I.—Investment and Annual Cost on Poles.

Table 1 shows sixteen sizes or combinations of poles suitable for suburban or semi-suburban conditions, fourteen of which are wood. In figuring the annual costs it is assumed that the value of pole will be entirely wiped out at expiration of given time. The steps can probably be used over again and the pole may have a slight resale value, but these at best will only cover removal costs. It will be noted that while the investment costs vary by over 100 per cent. the annual costs only vary about 35 per cent. Taking the average of these annual costs, which is $1.84 and eliminating all above the average we have the following to select from:—

	Cost.	Annual Charge.
[illegible] treated	[illegible]	$1.49
[illegible] steel	[illegible]	[illegible]
[illegible] steel	[illegible]	[illegible]
[illegible] treated butt retreated and reset	[illegible]	[illegible]
[illegible] treated, retreated and reset	[illegible]	[illegible]
[illegible] treated	[illegible]	[illegible]
[illegible] treated and reset	[illegible]	[illegible]
[illegible] treated and reset	[illegible]	[illegible]
[illegible] treated	[illegible]	[illegible]

[illegible] transformers, corner poles, etc. Assuming that every fifth [illegible] economy, and if such treatment should turn out to give a life as long as the makers of the carbolinium claim the economy will be very much greater. For this class of work the writer recommends the use of 30-ft. treated poles for branch secondary lines, using 6-inch for straight runs and 7-inch for strains and corners. For trunk lines requiring primary wires a 35-ft. pole should be used, 7-in. tops meeting all usual requirements. While the table gives the annual cost of such a pole as $1.84, the actual cost with above suggested arrangement is less owing to our having a good framed 30-foot pole left from the old 35-foot when it requires renewing at the end of 13 years. This brings the annual cost of the 35-foot pole down to $1.33 or less than the 30-foot poles. This saving would, however, not be possible unless we used 30-foot for standard branch lines, as otherwise the old cutoff 35-foot poles would be dead wood on our hands.

The theory of wood preservation must be clearly understood by those attempting the treatment if success is expected. Wood rot is caused by a living microbe, and to sustain life we must have all of three things—LIGHT, AIR and WATER. Each one of these microbes throws a tendril or thread to the point where all three of these conditions exist, and these tendrils may be many feet in length, as they are in the case of dry rot, or heart rot. Deprive these organisms of any one of the three essentials to life and we have solved the problem of preservation. If we keep our pole above ground in good condition to shed water, by filling all exposed end grains and preventing damage to the exterior surface, we have eliminated water from this part of the pole and insured against surface rot. A short distance below the ground line both light and air are eliminated, so that our danger zone is confined to a few inches above the ground and about one to one and one-half feet below the ground. It is this portion which requires preservative treatment and any compound which will permanently exclude the air fulfills the purpose, and it is not necessary that this extend entirely through the pole as the organism in going down through the heart can not obtain light and can not live. The only really successful compound for this purpose appears to be some of the coal tar by-products, of which the dead oil,

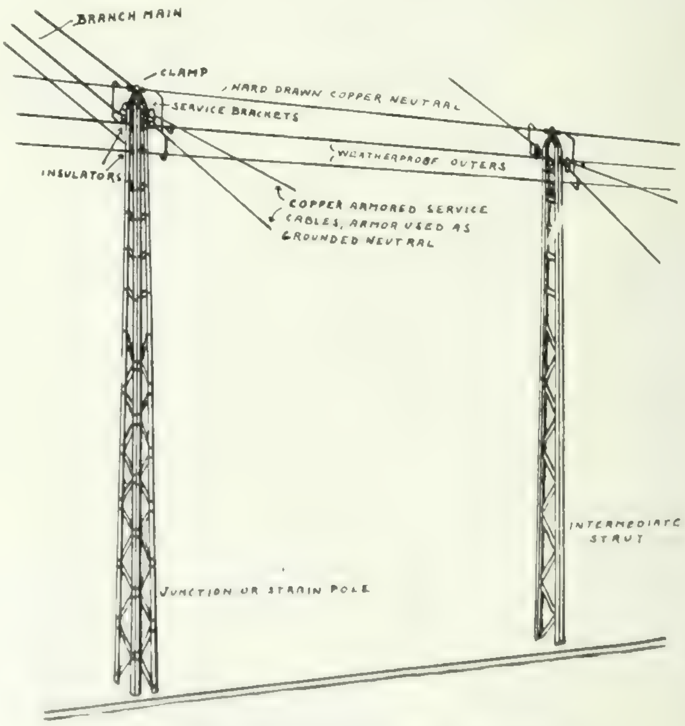

Fig. 1.—Steel Pole Secondary Distribution.

known to the trade as carbolinium, appears the best. A brush treating process can meet with but indifferent success owing to all timber being more or less filled with season cracks or checks, the interior of which can not be reached with a brush. The immersion treatment requires two open tanks, one for hot and one for cold oil, each capable of holding eight or ten poles, which are hoisted by a derrick and their butts set vertically in the tank. In addition a storage tank is desirable and a small circulating pump with suitable piping and valves connecting all three tanks. For heating the oil a furnace may be built under the hot tank, or, better still, a small steam boiler provided and steam coils immersed in the tank. Where current can readily be obtainable the heating can be done conveniently by means of low pressure resistance coils placed directly in the bottom of the tank, a suitable grid being placed to keep the weight of poles off the coils. Such an equipment should be installed for from $1,500 to $2,000, and will pay for itself in a very short time.

The growing scarcity of timber suitable for poles is rapidly forcing up the price until it seems that a few short years will make it necessary for us to use some other material with which to support our overhead lines. For voltages between those that can be handled with bare hands and those too high to handle alive a wooden or other form of insulated pole has its advantage. For high tensions transmission and for low tension secondary distribution, however, a metal pole has no objectionable features. It would seem, therefore, that we should conserve our remaining forests for use where wood is advantageous, and substitute some other material for the balance of our requirements. The past few years have seen many improvements along these lines, steel towers for transmission lines being used to-day almost exclusively. For trolley systems the tubular iron pole has been in use for urban lines for many years. Reinforced concrete has also been tried with varying success and gives promise of ultimately being successful.

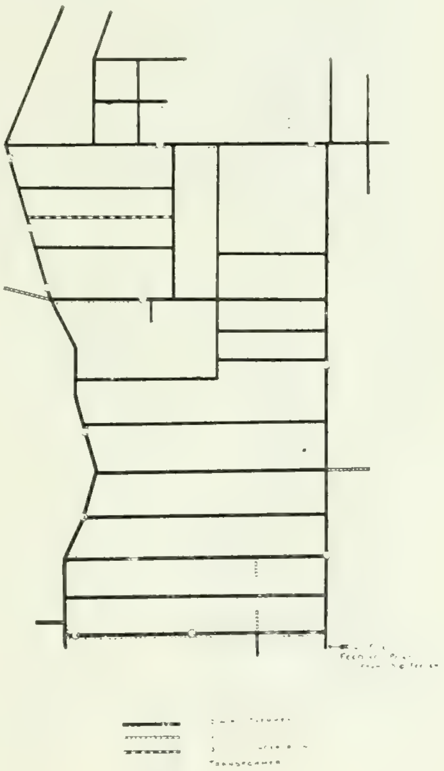

Fig. 2.

The concrete pole has been adopted for all secondary distribution by one of our larger Canadian cities, and we can well afford to wait and see how these work out before experimenting ourselves to any great extent. These poles are from 25 to 30 feet in height, of square section with beveled corners. They run about six inches at top and eight to nine at the butt. Reinforcement is with four one-half inch rods, one in each corner, about one inch from the surface. The cost in position is about the same as that of a treated cedar pole, and, theoretically, there should be no limit to their life. Personal observation, however, precludes their being recommended by the author. It is surprising the amount of rough handling these poles will stand and the extent to which they will bend without breaking. The peculiarity seems to be their failure after they are in position and the wires in place. Where they can be head-guyed so that practically no strain is placed on them they work admirably considered simply as props, with a vertical load only. Two forms of failure have been noted; first, that where the head guy has given and allowed a strain to come on the pole. In this case the beam has its fulcrum at the ground line and a tremendous leverage takes place, which draws the reinforcement, on the side under tension, right out of the concrete. This could be overcome by fastening the lower ends of the reinforcing rods in some kind of a plate, but would probably result in the strain breaking the rods instead of pulling them out. The other failure appears to be due to a torsional strain from uneven balancing of the wire pull at the top. In this case the outer shell of concrete near the top is entirely broken off and the rods with the concrete core piece twist around until the strain is equalized. On straight runs they may prove successful provided the use of numerous anchor guys is not objectionable; but in taking off service lines serious difficulties come up, as it is hardly practicable to side guy every pole where a service line is required.

Another apparent inherent defect in these poles seems to be the shrinkage cracks in the concrete. In many cases these are quite prominent and extend over three sides of the pole, being very pronounced on the side opposite the strain. It is very evident that the reinforcement is carrying all the strain and equally evident that water is getting at the rods, as well as air. As to just what effect this is going to have on the life of the pole time alone will tell.

The writer's idea of what would be a successful reinforced concrete pole would be to have a circular cross section, the reinforcement to be in the form of a tapered tube of either expanded metal or electrically welded mesh. To avoid deterioration this could be hot galvanized as a whole at small expense. The concrete would be moulded around this tube, which should be covered not less than one and one-half inches. To lighten the pole and save concrete a tapered mandril about two inches smaller than the inside of the reinforcing tube could be placed in the mould and withdrawn after the concrete had partially set. A pole of this kind would require pouring with the mould set on end, the entire proposition of development being one almost too great for any individual company to handle alone. Some of our enterprising manufacturers will, no doubt, eventually take up the development of such construction and put it in commercial shape.

Tubular steel poles up to 30 feet are now a standard product. A pole of this height and heavy enough for distribution strains can be set in concrete at a cost of about $30.00 each. Where provided with a reinforcing band at the ground line and the concrete carried up sufficiently above ground to act as a water shed the life should be at least 25 years. With this life and allowing for its scrap value the annual charge would be $2.46, or about two-thirds greater than for a wooden pole. At the rate the cost of timber is going up a few years will put iron and wood on an equal footing for such use.

Structural iron poles can be developed easily along the same lines as standard transmission towers, but on a smaller scale. One company is now making a light three-legged tower at very moderate cost and numerous designs could be brought out using galvanized standard shapes and giving a pleasing appearance with ample strength. A built up pole can be made at a cost in position not exceeding twenty dollars. The life should be at least twenty-five years with an annual cost of less than $2.00 or little greater than a wood pole line. In fact, the writer has in mind at the present time a system of construction in which about every fifth or sixth pole would be of the tower type (see Fig. 1), the intermediate poles being simply latticed struts set to take up a right angle strain due to service lines. The tops of these poles would be solidly connected by a hard-drawn copper wire which would act as a stay wire, and also a grounded neutral for the distribution system. The annual cost per pole for this idea will run approximately $1.60, or about the same as the wood pole line. These costs can probably be further cut down by bolting new ground sections to the old poles at the expiration of the original life, as little or no depreciation should occur above the ground if four test galvanizing is insisted upon.

Pole Fittings and Hardware.—The permanency, reliability and overhead charges of a distribution system depend probably more on the hardware and fittings used than upon any other item of construction. In the days of early development very light poles were the rule and their life was generally not over five years; consequently, any fitting which would last as long as the pole was considered good enough.

With the adoption of a treated pole giving a life of twelve years or more very different fittings are required. For high tension lines, or those of over 600 volts, the wooden cross arm is probably the best means of supporting the wires, as its insulating qualities are of considerable advantage. Cross arms of standard dimensions as specified in the overhead line committee's report of the National Electric Light Association, together with the hardware for cross-arm attachment as specified in this report, should be used by all electrical distribution companies where the wires are supported on cross-arms. The standard sizes are not only those which practice has shown to be suitable for the work; but, even with the greatest care, accidents are bound to happen and an acknowledged standard method of construction is of considerable advantage in defending a lawsuit. The ordinary cross-arm, however, even where of standard dimensions, is not good enough for use with treated poles unless specially selected and treated. An exception to this may possibly be made if the arms are of genuine hard yellow pine. This grade of wood is expensive and very heavy to handle, and, while strong, is not nearly as strong as its weight would seem to indicate. The softer woods, such as stock arms are generally made from, are absolutely worthless unless treated. These arms generally show heart rot first, and may appear perfectly good on the outside and actually be but a shell, which indicates that the weak point is the exposed end grain in the pin holes. To overcome this it naturally follows that any method of treatment must be before the pins are inserted and also that a brush treatment is useless. For treated cross-arms straight grain clear spruce is without doubt the best material. Arms of this [illegible] strong and tough for their weight. If treated with carbolinium oil the wood should be first kiln dried and then immersed in the hot oil until it refuses to absorb any more, several successive baths being given: the final one being in cold oil. The best [illegible] Kyanizing, in which the timber is rendered absolutely sterile and will [illegible] conditions. Kyanized timber is to all appearance the same [illegible]

arms only locust pins should be used and only those with 1½-inch shanks. Oak pins are just about as treacherous as stock cross-arms as they rot off at the shoulder in a short time. When it is considered that a broken pin may cause an interruption to an entire distribution system, and that the proportionate costs of the pins in comparison with total cost of the line is infinitesimal, any attempt at economy on this article is worse than poor engineering, and is, in fact, criminal if the pole line is on a public highway. For the same reason, too much dependence should not be placed on a single pin, and double arms should be used at all angles and junctions, and, preferably, also on the first pole on each side of a strain pole. These double arms should be provided with two spacing or spreader bolts in addition to that holding the arms in position. Various forms of spreaders have been tried out from time to time; but the writer has found the best form to be a wood block with a transverse hole to receive a standard through bolt. These blocks are frequently made in the field from a section of standard cross-arm, but a far better practice is to have them made from 3-inch by 4-inch surfaced stock, treated the same as the arm. The blocks may be made in lengths of from 18-inch to 24-inch, and can then be cut to proper length as required; the 11/16-inch hole being bored through the entire block at the mill.

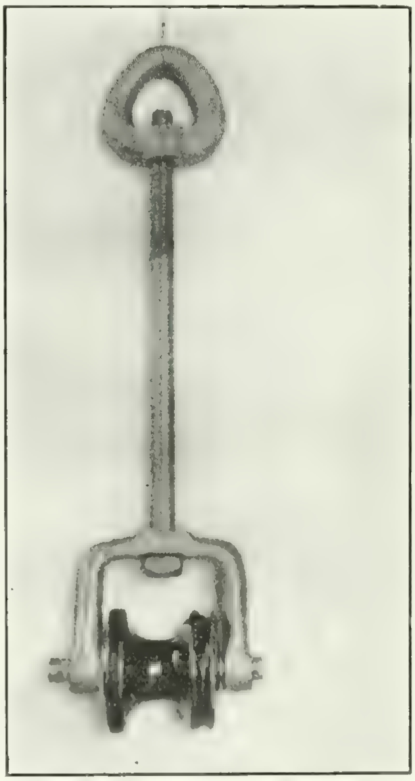

Fig. 3.—Dead Ending Clevis.

Locust wood suitable for pins is becoming so scarce, and, at best, a wood pin is the weakest point in our suspension system, that metal reinforcement or entire metal pins are being used more and more as the demand for permanent construction increases. These pins range all the way from the ordinary wood pin with a ⅜-inch iron rod inserted in it to the all metal pin. Attempts have been made to standardize a metal pin of malleable iron having a 1½-inch shank to fit the old style of arm. This style has not found favor, however, owing to the arm then becoming the weakest point. Malleable pins have also been found objectionable owing to the tendency to split the insulator due to unequal expansion between the iron and the glass or porcelain. In order to overcome this, metal pins with wooden tops are used extensively, the common form being simply the old wood pin cut off at the shoulder and bored to receive a [illegible]-inch carriage bolt. A similar style uses only the threaded portion of wood, the base being a porcelain spool which slips over the bolt. Probably the oldest style of metal pin is the Western Union, which has been standard for many years with telegraph companies. This pin has not, however, the necessary stiffness for electric light work.

(To be continued.)

PRECISE LEVELLING IN CANADA.*

By F. R. Reid, D.L.S.

While this paper has the rather comprehensive title of "Precise Levelling in Canada," it should be explained at the outset that it has special reference to the methods employed and the territory covered by the Geodetic Survey and it is intended to merely touch upon the work of other branches of the Government service along these lines. In this country, the only precise levelling of any extent, so far as I am aware, is that which has been carried out by the Government, though in the United States some of the railways, notably the Baltimore and Ohio and the Pennsylvania Railroad, has undertaken precise level lines of considerable extent on their own account.

This fact, namely, that some of the leading American railroads have gone to the expense of running precise levels for their own benefit, does much to prove the demand for levels of a high degree of accuracy; also, I might say, that while the work has been carried on for only a comparatively short time in Canada—the first work by this Department was done in 1906—and is therefore not very widely known, yet we have had a large number of enquiries for the results, from railway corporations, city engineers, suveyors, consulting engineers and others. While the work is of great use to the public at large it is of equal importance to the Geodetic Survey in the extension of its system of triangulation, and to the various topographical surveys carried on by the Militia and other Government Departments; also to the International Boundary Survey. The making of accurate contour maps of any country is very greatly facilitated by a line or a net of precise levels.

If any further proof were needed for the necessity of this work, a perusal of White's dictionary of "Altitudes in the Dominion of Canada," would furnish a good deal of it. This is a very comprehensive work and has been prepared with great care from the best available information, obtained from many sources. In this preparation, however, many very large discrepancies in the elevations of junction points of railways, &c., were discovered, which it was found impossible to overcome by the use of the information at hand. I will instance three or four cases on the main line of the Canadian Pacific Railway from Vancouver to St. John, N.B.

The elevation published for Donald, B.C., by levels from the Pacific Ocean is 2,586 feet above the sea level, and by levels from Lake Superior, 2,574, a discrepancy of 12 feet. At Cartier, the first divisional point west of North Bay, there is a similar descrepancy of 34 feet between the levels from Lake Superior and from Montreal. At two points on the line through the State of Maine, also, there are discrepancies, one of 18 feet and one of 7 feet. These discrepancies all have the same sign and therefore accumulate in the same direction, to the total amount of 71 feet. While there may be a slight difference in elevation between the Atlantic and Pacific oceans along the respective coast lines, it would certainly amount to but a small fraction of this difference, and an investigation by means of precise levelling would seem to be in order.

Precise levelling is, whenever possible, carried along railway track, rather than along highways or across country, the advantages of this practice being many. The rate of rise and fall of the track is usually fairly uniform and no steep hills are encountered, thus allowing longer average sights to be taken and allowing the backsights and fore sights to be easily kept of equal length. The rails furnish excellent support for the levelling rods and thus the time is saved which would otherwise be consumed in putting artificial turning points into the ground. The masonry structures—bridges and culverts—situated along the railways are utilized for placing permanent bench marks; this is of great advantage both to us and to the railway companies. Again, the use of a hand-car for going to and from work and for moving along from point to point during the day affects a great saving of time and labor, and the transportation of the camping outfit from camp to camp by freight is cheaper and more convenient than the method by horse and wagon. Against these and many other advantages may be set the fact that the refraction and boiling of the atmosphere in the heat of the bare ballast and rails of a track is worse than on a highway. Dodging fast trains coming through rock cuts and around curves lends a spice of danger and excitement to the work which would not be found on a country highway.

The levels of the Geodetic Survey in Ontario and Quebec have been started from a bench mark established by the United States Coast and Geodetic Survey at Rouse Point, N.Y. This bench mark is included in an elaborate net of precise levels and water transfers which are based on mean sea level at New York and its adjusted elevation is believed to be very close to the truth. At any rate it is the best available datum at present; eventually the Geodetic Survey may have a mean sea level datum of its own but this is something which requires several years of gaugings to determine accurately.

From Rouse Point two lines of levels have been extended, one westerly through Lacolle Junction, Coteau Junction, St. Polycarpe Junction, Kemptville, Prescott, Hamilton, London and Chatham to Windsor, with a branch from Hamilton to St. Catharines and Bridgeburg; the other line easterly through St. Johns and Sherbrooke to the International Boundary, 15 miles east of Megantic, Que.; branches have been extended from this line to the International Boundary from Farnham, Foster, Sherbrooke and Lennoxville, and from Megantic to the St. Lawrence River at Levis via the Quebec Central Railway. A considerable amount of levelling has been done in New Brunswick and Nova Scotia; starting from the town of St. Stephen a line has been extended northerly to the St. Lawrence River at Riviere du Loup, this line runs for most of its length within a short distance of the border of the State of Maine and branches have been connected at intervals so as to furnish accurate levels for the International Boundary survey. Easterly from St. Stephen the line has been extended through St. John and Moncton and through Nova Scotia as far east as Mulgrave, on the Strait of Canso.

All the elevations in the Maritime Provinces are based—provisionally— on a bench mark at St. Stephen, N.B., established by the United States Corps of Engineers; connections have been made at Riviere du Loup and Moncton with the precise levels of the Public Works Department of Canada which have been carried from Montreal to Halifax via the Intercolonial Railway; these levels are connected with the Rouse Point bench mark and also with mean sea level at Halifax. The fact that our levels agree very closely with theirs goes to show that the St. Stephen bench mark is very near correct and that the elevations of our bench marks throughout the Maritime Provinces are very close to the truth and of far greater accuracy than is necessary for ordinary engineering and surveying purposes. Last summer a start was made at levelling along the Grand Trunk Pacific Railway, from its junction with the Quebec Central Railway on the Megantic-Levis line to the town of Edmundston, N.B., on the St. Stephen Riviere du Loup line, a distance of some 25 miles — through a very rough country. It is hoped that this link may be finished during the present season and then all the bench marks in the Maritime Provinces may be corrected by a small constant quantity, which will reduce them to the same datum as those throughout Ontario and Quebec, and will form one net of levelling extending from the Maritime Provinces to Western Ontario.

---

*Paper read before the Ottawa Branch of the Royal Astronomical Society.

In Western Ontario, two circuits, composed entirely of our own levelling, have been completed, and the excellent results—shown by the small closing error—are a source of great satisfaction. As mentioned above, a main line of levels extends from Toronto to Windsor, along the Grand Trunk Railway through Hamilton, London and Chatham; a branch line leaves this at Toronto and extends along the Canadian Pacific Railway to Owen Sound, thence southerly along the Grand Trunk Railway, through Palmerston, Listowel and Wingham to a connection with the main line at Hyde Park Junction, 4 miles west of London. Another line leaves the Owen Sound-Hyde Park line at Lucan Crossing, 15 miles north of Hyde Park Junction, and extends through Sarnia to Chatham, where a second connection is made with the main line. The new elevation found for the bench mark at Hyde Park Junction is 0.15 feet higher than the original elevation and at Chatham 0.11 feet lower than the original. The length of the Toronto-Hyde Park circuit is about 436 miles and the length of the Toronto-Chatham circuit about 595 miles so it may easily be seen that the levelling shows a high degree of precision in actual practice.

In the spring of 1910 levelling was inaugurated in the Western Provinces. To secure a sea level datum for this work it was found necessary to go to the town of Stephen, Minn., about 45 miles south of the International Boundary at Emerson, Man. The precise levels of the United States Coast and Geodetic Survey having been extended to this point, furnished what was desired. It was necessary to carry the levels through United States territory to the International Boundary at Emerson, the boundary was then followed to Gretna, a few miles west, and the railways paralleling the boundary followed westerly from that point. As in the case of the Maine and Vermont boundaries, so here, branch lines have been run at convenient intervals for the benefit of the International Boundary Survey. The levelling, at the close of last season, had reached the village of Frobisher, Sask., about 27 miles east of Estevan, on the Canadian Pacific Railway.

Returning to Ontario, the programme for the present season, includes running from Bolton on the Toronto-Owen Sound line, towards Sudbury via Canadian Pacific Railway, and it is hoped that this line will eventually be extended west to connect with the line mentioned above as running west from Emerson; this will, however, be the work of several years owing to the great distance involved.

From a consideration of the various routes outlined above, it will be seen that the general policy has been to extend [illegible] lines of levels throughout the country as [illegible] for the immediate use of the [illegible]; as these lines are completed, duplicate lines may be run and circuits of levelling closed. In following routes between principal points it has been usual to follow the line which passes through the best settled country and possesses the greatest number of [illegible], except in a few cases the route has been [illegible] in order to connect with [illegible] published work done by the Public Works Department, as in the case of our line between Coteau Junction, Que., and Prescott, Ont., the Department had levelled from Coteau to Cornwall, consequently, to avoid duplication, the levels of the Geodetic Survey were carried around by St. Polycarpe and Kemptville an extra distance of about 19 miles.

The Public Works Department has conducted precise levelling at intervals since 1883. During the years 1904-05-06 a long line of levels, starting from the Rouse Point bench mark, was extended through Ottawa and Pembroke to North Bay, for use in the extensive surveys undertaken by the Department for the purpose of locating and determining the cost of the projected Georgian Bay Ship Canal; this line was checked by a line from Toronto to North Bay, starting from a bench mark at Toronto which had been established by means of water transfers from Tibbett's Point, N.Y., at the eastern end of Lake Ontario.

Precise levelling was carried on by the International Boundary Survey in connection with the survey of the 141st meridian, the boundary between Canada and Alaska, in 1908-09-10. Starting from White Pass, B.C., levels were carried along the White Pass and Yukon Railways to White Horse and thence by wagon road to Dawson and over the glacier trail to the 141st meridian; the total distance levelled was in the neighborhood of 500 miles, but this distance does not give a proper idea of the amount of labor involved, owing to the fact that most of the work was not on a railway track but on rough trails through an uncivilized country.

The instruments and methods employed on this work were practically the same as those in use by the Geodetic Survey, modified when necessary to suit the different conditions under which the levelling was performed.

Bench Marks.—In the foregoing, mention has been made of the bench marks established; it will now be in order to say something of the nature of these—the only permanent field records of the work performed.

The standard bench mark established by the Geodetic Survey, previous to the year 1908, consists of a copper bolt ½ inch in diameter and 4 inches long, stamped on the end with the letters "B.M., D.A.O." (Bench Mark, Dominion Astronomical Observatory). During 1908 and since then the standard bench mark has been a copper bolt, ¾ inch in diameter and 4 inches long, stamped on the end with the letters "G.S.C., B.M.." (Geodetic Survey of Canada, Bench Mark). In either case the bolt is sunk horizontally in rock or masonry, a hole being drilled of the exact size of the bolt or a shade larger and the latter hammered in till it completely fills the hole, the end being flush with the surface of the masonry or projecting slightly; properly put in, it is impossible for anyone to remove it without destroying the surrounding rock or masonry. After the exposed end has been planed to a smooth surface by means of a file it is stamped with a steel die containing the above mentioned letters; then a horizontal cross mark is made with a cold chisel, upon which the elevation is taken; finally a number is stamped with other steel dies. The question is often asked "Why do you not indicate the elevation of the bench mark also?" In reply to this I would say that the elevation of a bench mark in a precise levelling net may never be finally determined; the closing of circuits and introduction of new cross lines will always call for adjustments which will make changes of greater or less magnitude in the elevations; it would therefor be impossible to place more than an approximate [illegible] upon it. Also the computation of the elevations from the field notes is a work of some magnitude and would delay the operations of the parties were it performed in the field, and is therefore left to be done in the office after the notes have all been carefully checked. I might say also that an engineer would not usually attempt to look for the bench marks haphazard, but would secure descriptions of their locations, when getting these, the elevations can always be secured at the same time without difficulty. Bench marks are placed in the stone and concrete structures along the railways, sometimes in large boulders and in rock cuts, and when towns or cities are situated within a reasonable distance of the line, branch lines are run to them and bench marks placed in public buildings such as post offices, court houses, and churches. Levellers are instructed to place bench marks at distances of three miles apart, or less. It has been found impossible however, in many cases, to secure good locations for bench marks at anything like this distance apart, so the expedient was adopted by us in Manitoba in 1910, and in this part of the country in 1911, of building concrete piers, specially for bench marks.

These piers are 6′ 3″ high, 9″ square at the top and 15″ square at the bottom, resting on a 6″ concrete footing; the whole pier is buried to within about 9″ of the top and the copper plug built in, near the ground surface, having been previously stamped and numbered. The piers are usually built on the railway right-of-way, within 3 or 4 feet of one of the fences and on fairly level ground, where they will not be exposed to danger from future alterations in the railway grade. The concrete consists of a mixture of one part cement, 2 parts sand, and 5 parts gravel, the latter ingredients can often be secured by sifting the ballast on the track. Portable wooden forms are employed which can be removed after the concrete has set and used over again; the total time consumed building a pier, including the excavating, removing the forms and back-filling, averages between half a day and one day, probably nearer the latter.

The piers are not built at any definite distance apart; it is left to the discretion of the leveller to put them in where they appear to be necessary.

Temporary bench marks are placed at intervals of one mile or thereabouts, they consist usually of spikes, driven horizontally into telegraph poles, and, as their designation implies, they are used only for convenience while the work is progressing; they are not embodied in the final office record.

The permanent bench marks above described are neat and unobtrusive, not likely to be discovered and defaced by unauthorized persons, but easily found by anyone furnished with a description, and are therefore well adapted for use in a settled country like that in which most of the work of the Geodetic Survey has been carried on.

For use along the Alaska Boundary, however, they were not considered suitable, owing to the absence of masonry structures and for other reasons, so a different form of bench mark was employed, being a circular copper plate 4″ in diameter with a stem at right angles to the plate and about 3″ long; the plate was placed flat on top of a surface of rock, the stem being solidly cemented into a hole drilled for that purpose; the elevation was taken on top of a knob at the centre of the plate. When suitable rock could not be found the copper plate set on the top of an iron post which was firmly planted in the ground, projecting a short distance above the surface. Bench marks were put in at distances of 10 miles or thereabouts.

The bench mark used by the Public Works Department is similar in form to that of the Geodetic Survey, but contains no mark on its exposed surface but the cross mark upon which the elevation is taken, the number of the bench mark is cut in large Roman numerals upon the masonry adjoining it.

Instruments.—The instrument adopted is a precise level very similar in design to that used by the United States Coast and Geodetic Survey. It may be described as a modification of the engineer's dumpy level in that the telescope is firmly attached to its supports and is not removable as in a wye level. The materials used are nickel-iron, an alloy consisting of 36 parts nickel and 64 parts iron and nickel-steel (or Invar) an alloy of the same proportions of nickel and steel. The latter alloy is used for the mountings of the level vial, for the collars, diaphragms, adjusting screws and any other parts required to retain their relative positions as nearly as possible. The co-efficient of expansion of these alloys—especially nickel-steel is exceedingly small.

The instrument base is a single piece of hard and finely grained cast-iron and is supported by the three levelling screws. The instrument centre is of unusual length and passes down through a hole in the tripod head, thus allowing the telescope to rest low down—near the tripod— and giving greater stability to the instrument when used in a wind. The telescope itself is completely enclosed in an outer tube in which it is allowed a small motion vertically; it is supported at the object glass end by a horizontal pivot and at the other end rests on the point of a fine micrometer screw by means of which it may be raised or lowered by an exceedingly small amount. When the instrument is not in actual use and is being carried from station to station the telescope tube is lifted from the point of the micrometer screw by means of a small lever; this keeps the telescope pressed tightly against the upper part of the casing and saves the point of the screw from wear. At the lower end of the screw a drum or micrometer head, subdivided by a hundred graduations, is provided. The upper part of the outer casing has cast into it a rectangular opening with a framing surrounding it; a piece of plate glass fitted into this framing in grooves closes the opening against dust or air currents, but can be quickly removed, when necessary, for the purpose of adjusting the level. The tube containing the level vial is set within this opening, as close to the line of collimation as possible. This position of the vial has the advantage of protecting it, to a large degree, from sudden changes of temperature. A small rectangular mirror placed above and parrallel to the level tube, reflects the bubble into two prisms placed in a tube immediately to the left of the telescope tube. By this means the observer is enabled to watch the action of the bubble with his left eye while reading the rod with his right eye; that is, he can transfer his attention instantaneously from the one to the other. The level vial is constructed with a small chamber at one end communicating with the body of the vial by an opening at the edge of the tube; by tilting the instrument so as to raise one end of the vial the spirit can be raised to run to or from the chamber; in this way the length of bubble used may be kept constant throughout the varying temperatures of the day or the season. This adds to the refinement of the work, as the grinding of the vial is more accurate near the centre and it is consequently not well to allow the bubble to lengthen out too much. One division on the level vial has a value of about 2½ seconds in arc.

Three cross wires of fine spider web are placed in the diaphragm, in order that three readings of the rod may be made at each observation. Two eye-pieces, of different powers of magnification, are provided; the high power to be used under ordinary atmospheric conditions, and the low power when the trembling and boiling of the atmosphere, due to heat waves, is unusually severe.

Great care has been expended on the construction of the rods used up on this work. They are built up of separate pieces of white pine giving a cross section in the form of a symmetrical cross so as to prevent bending and warping; they are boiled thoroughly in paraffin which tends to keep them of constant length under varying conditions of atmosphere and temperature. Silver plugs are inserted in the face of the rod approximately at the three, six and nine foot points and the exact position of these points marked by a fine scratch on the face of the plug; the rod is then subdivided into feet, tenths and hundreths in alternate white and black spaces of one one-hundreth of a foot. When observing the rod the readings are made to thousandths, the hundreth spaces being subdivided by estimation. As it is impossible to subdivide a black space accurately at the distance the rod is usually observed, two sets of graduations are placed, side by side, one on each side of the centre line of the rod, the white spaces of one adjoining the black spaces of the other; thus the observer has always a white space to subdivide by reading on the right hand or the left hand set of graduation marks, as the case may be. The bottom of the rod is formed of a cast steel foot block with a hemispherical knob on the bottom, suitable for holding on flat surfaces.

Another piece of apparatus which can hardly be classed under the heading of instruments, but which is very necessary nevertheless, is a large carriage umbrella with a handle about 8 feet long, provided with a spike at the end to insert it in the ground. The umbrella is used whenever the sun is shining while observations are in progress to shade the instrument from its rays; without this the parts would become unequally heated and irregular and unreliable action of the bubble would follow.

While carrying the instrument between sights a cover of duck or cravenette is used for the same purpose, this also is used to protect it when working during a light rain; in a heavy rain the work has to be discontinued.

Field Operations.—A precise levelling party consists of 7 men, the observer, the recorder, umbrella man, two rodmen, cook and railway man, usually a section man or brakesman, to pilot the hand-car. Camps are made at the stations along the line, the distance apart of camps varying from ten to twenty miles according to the location of towns and villages and to the condition of the intervening track or to grades. The levelling is carried continuously forward, day by day through the camp and to a point about half way to where the next camp ahead will be; permanent and temporary bench marks being put in so as to divide the line into sections of one mile or less. From this point backward levelling is commenced and carried along to the point where the line was taken up, probably about half way from the previous camp, all bench marks being checked upon on the backward run.

I will quote from the general instructions issued to levellers:—"All lines are to be levelled twice, in opposite directions called forward and backward levelling. Backward shall in every respect be independent of forward levelling and the same tuning points shall not be used. If the forward levelling is made in the forenoon, the backward—over [illegible] In this respect the opposite conditions as to intensity of light [illegible] When [illegible] in the thread intervals, or any other error is discovered, even [illegible]

[illegible]

[illegible] led anew, both forward and backward, until two measurements within the limit of error are secured. In this way, four, six, or more measures are made, the mean of all being taken and the individual residuals determined. Reject all those results whose residuals are greater than 0.015 feet; then take a mean of the remaining measures for a final result."

This requirement, that the discrepancy shall be within 0.017 times square root of the distance in miles has been adhered to as closely as possible through out the work; this means that for 1 mile forward and backward levels shall correspond within 0.017 foot, for 4 miles within 0.034 foot, for 100 miles within 0.170 foot and so on. Quite frequently the total discrepancy of a line shows a constant, and often unaccountable, tendency to accumulate in one direction. Various precautions are used to guard against this. If, when reading from the successive instrument stations, or set up points, the rear rod were always read first and the forward rod last, any settlement of the level between the backsight and foresight would have a constant tendency to make the foresights too small in comparison with the backsights, and on the backward levelling this effect would be repeated, causing the discrepancy to accumulate rapidly; this is obviated by reading on the rear rod first at one station and on the forward rod first at the next station so that any settlement at one will be counteracted by the settlement at the next; this method also has the advantage of eliminating the effect of a uniformly changing refraction in the atmosphere, such as usually occurs most noticeably in the early morning and late afternoon hours. It of course has the effect of holding back the progress of the work considerably, a at every second set up the leveller has to wait for the front rodman to reach his turning point, and afterwards wait for the rear rodman to ovetake him before going forward (these remarks are intended to apply where the levelling is carried along a railway track and a hand-car used between sights). However, in precise levelling, accuracy is the first consideration and speed is secondary.

(To be continued.)

EDMONTON INVESTIGATES TOFIELD'S GAS SUPPLY.

A heavy flow of natural gas has been struck at the town of Tofield, on the main line of the Grand Trunk Pacific, forty miles east of Edmonton. The town has been conducting boring operations as a municipal enterprise for about a year past. For some time strong indications of gas were evident, and it was obtained in comparatively small quantities, and could not be considered a commercial proposition until a few days ago, when there was encountered an enormous flow under very heavy pressure. The volume of the flow is variously estimated at from 1½ to 2 million feet per day. Edmonton city council has taken action with a view to obtaining expert information as to the practicability of piping this gas into the city. The city is about to embark on the installation of a municipal gas plant. The work will be immediately proceeded with so far as the mains are concerned; but action on the ordering of the generating plant will be suspended until the possibilities of the Tofield discovery have been investigated.

Practically at the same time a strike of gas in large volume and under heavy pressure was made at Pelican Rapids, about 175 miles north of Edmonton, on the Athabasca River. Boring has been going on there for oil in the interests of a syndicate of Edmonton capitalists, and will be proceeded with, with the expectation of finding oil in strata below.

ELECTRIC POWER FOR ST. JOHN, N.B.

An engineer has stated that a head of 100 feet of water could be got at Silver Falls on the line of the city waterworks system, and a constant pressure secured by the construction of storage dams. The city council is considering the question of generating electricity at this point, in order that the city might provide its own electric light system. The council has awarded contracts for permanent paving on portions of several streets, and this policy will be continued from year to year. City government under the commission plan is thus far working out satisfactorily in St. John, and much more so than the old city council system with ward representation.

Mr. D. McNicoll, general manager of the Canadian Pacific Railway, visited St. John last week and stated that the plans for the new million-bushel elevator had been completed, and the contract would be awarded very soon. A crib-work has been constructed, and the Maritime Dredging Company has been awarded the contract to fill in a section of the shore flats at West St. John, where the elevator will be built.

At East St. John the sub-contractors for the breakwater and the excavation for the drydock have just installed the heaviest construction plant ever seen in St. John. It was brought from Ohio and includes a steam shovel weighing 110 tons. Hundreds of men are now employed there. At West St. John Contractor Michael Connolly has brought from Quebec a complete modern plant for concrete wharf construction, and has the heavy crib-work foundations for the new wharves which he is to build well under way.

The Furness steamer Rappahannock has just taken from St. John a shipment of fifty thousand bushels of grain for London. It is expected that each steamer of this line during the summer will take about the same quantity, and this will be a test of the suitability of St. John as a summer port for grain shipments.—W.E.A.

◆

PERSONAL.

MR. DE GASPE BEAUBIEN has been appointed as representative of the city of Montreal on the Electric Service Commission, to succeed Mr. Beaudry Leman.

◆

CORRECTION.

In May 9th issue of The Canadian Engineer, on page 636, the formulae should read as follows:

$$\frac{\left\{\frac{A'B' + A''B''}{2} \times A'A''\right\} + \left\{\frac{C'D' + C''D''}{2} \times C'C''\right\}}{2} \times$$

$$\frac{(C'C - A'A) + (D'D - B'B) + (D''D - B''B) + (C''C - A''A)}{4}$$

$$\times \frac{62.5}{2{,}000} = \text{Displacement in tons.}$$

which can be expressed in a somewhat simpler manner:

$$\frac{\left\{\begin{matrix}\text{Area of boat}\\ \text{on loaded water lines}\end{matrix}\right\} + \left\{\begin{matrix}\text{Area of boat}\\ \text{on light water lines}\end{matrix}\right\}}{2} \times$$

$$\left\{\begin{matrix}\text{distance}\\ \text{between the}\\ \text{two planes}\end{matrix}\right\} \times \frac{62.5}{2{,}000} = \text{Displacement in tons}$$

INTERNATIONAL GEOLOGICAL CONGRESS.

The International Geological Congress, on the joint invitation of the Government of Canada, the Provincial Governments, the Department of Mines, and the Canadian Mining Institute, will hold its twelfth meeting in Canada during the summer of 1913.

For purposes of organization, a meeting of representatives from various scientific bodies of Canada was held in Toronto, Ontario, on December 2nd, 1910.

Field Marshal, His Royal Highness the Duke of Connaught, Governor-General of the Dominion of Canada, has graciously consented to become honorary president.

It is proposed to hold the meeting of the congress in Toronto, beginning on or about the twenty-first day of August. The congress will continue in session for eight days.

Since the first meeting of the congress in Paris, in 1878, meetings have been held in Italy, Germany, England, the United States of America, Switzerland, Russia, Austria, Mexico and Sweden. At the last congress held in Stockholm, in 1910, there was on attendance of 850, and it is expected that this number will be exceeded in Canada next year.

An extensive series of excursions is being arranged to illustrate the typical geology and mineral resources of Canada. These excursions will take place during August and September and will extend from Cape Breton and Halifax on the Atlantic to Prince Rupert and Victoria on the Pacific, and from Niagara Falls on the southern boundary to Dawson City near the Arctic Circle.

Geologists from every quarter of the globe will attend the congress, and for many it will be their first visit to Canada. They will include professors from the leading universities and mining schools, officers of the various government geological surveys and mining departments, and geologists and mining engineers in private practice.

Topics for Discussion.—The following topics have been selected by the executive committee as the principal subjects for discussion:—

1. The coal resources of the world.
2. Differentiation in igneous magmas.
3. The influence of depth on the character of metalliferous deposits.
4. The origin and extent of the pre-Cambrian sedimentaries.
5. The sub-divisions, correlation and terminology of the pre-Cambrian.
6. To what extent was the Ice Age broken by interglacial periods?
7. The physical and faunal characteristics of the Palæozoic seas with reference to the value of the recurrence of seas in establishing geologic systems.

The executive committee of the eleventh congress, held in Sweden, compiled and published a comprehensive report on the Iron Ore Resources of the World. The present executive has undertaken the preparation of a similar monograph on the Coal Resources of the World. In order to make the work as complete as possible the co-operation of all the principal countries of the world has been invited. This invitation has met with a cordial response, and it is hoped the volumes will be ready for distribution before the meeting so that they may constitute a basis for discussion at the congress.

The secretary will be pleased to answer all enquiries regarding the arrangements for the congress. Correspondence should be addressed as follows:

The Secretary, International Geological Congress,
Victoria Memorial Museum, Ottawa, Canada.

THE NEW CHIEF COMMISSIONER OF THE DOMINION RAILWAY BOARD.

Henry L. Drayton, K.C., one of Canada's representative attorneys, was born at Kingston, Ontario, Canada, April 27th, 1869. His father, Philip Henry Drayton, K.C., is of English birth and ancestry, and came to Canada as captain of the 16th Rifles of England, being stationed at Kingston, Ont. He retired from the Rifles in 1871, moving to Barbadoes, residing there until 1874, when he returned to England, and in 1877 moved to Toronto, entering the law firm of McMurrick and Drayton. He is at present official arbitrator of the city of Toronto. On the maternal side Margaret S. (Covernton) Drayton, is of Irish-Canadian lineage.

Henry L. Drayton was educated at the schools of England and Canada, and began his career as a law student in 1886, at Toronto, with the legal firm of Lount & Marsh. He was admitted to the Bar of Ontario in 1891, and at once entered in the practice of his profession. In 1893 he became assistant city solicitor, under C. R. W. Biggar, K.C., and subsequently under Sir William Meredith, K.C., and J. S. Fullerton, K.C. In September, 1900, he retired and went into partnership with Charles J. Holman, K.C. On the 29th of January, 1904, he was appointed county crown attorney for county of York, resigning from that office in November, 1909, to resume the practice of law with C. J. Holman, K.C. On January 20th, 1908, Mr. Drayton was appointed a K.C.

Mr. Henry L. Drayton, K.C.

[illegible] he was appointed counsel to corporation of Toronto, [illegible]. He was appointed by the Ontario Government a member of the Toronto Power Commission on May 11, 1911.

He is a member of Toronto Club, Toronto Hunt Club, Ontario Jockey Club, Rosedale Golf Club, Glen Major Fishing Club, Toronto Racquet Club, and Engineers' Club, of Toronto.

Mr. Drayton was married to Edith Mary (Cawthra) [illegible], of [illegible], September 14th, 1892, and they are the parents of three children, Grace Drayton, Nora Drayton and Margaret Drayton.

Mr. Drayton will take up his duties as chief commissioner of the Dominion Railway Board about September 1st.

WESTERN CANADA IRRIGATION ASSOCIATION.

SIXTH ANNUAL CONVENTION.

The Western Canada Irrigation Association will hold its sixth annual convention in the city of Kelowna, Okanagan Valley, B.C., August 13, 14, 15 and 16. The meeting will convene on the evening of the 13th, at 8 o'clock.

An excellent programme of addresses has been arranged, papers having been promised by the following:—

Professor Alfred Atkinson, Department of Agronomy, Montana Agricultural College and Experimental Station, Bozeman, Montana, "The Irrigation of Alfalfa."

Rev. E. McQueen Gray, foreign secretary, National Irrigation Congress, professor University of New Mexico, Albuquerque, N.M., "Foreign Government Reclamation."

William Pearce, former president of the association, and member of present executive.

Professor C. I. Lewis, State Agricultural College, Oregon, "The Relation of Irrigation to Fruit Growing."

P. H. Moore, superintendent Government Experimental Farm, Agassiz, B.C., "Stock and Dairying, with Special Relation to Irrigation Farming."

M. L. Dean, State Horticulturalist, Missoula, Montana, "Apple Culture and the Baldwin Spot."

A. E. Ashcroft, chief engineer, White Valley Irrigation and Power Co., Vernon, B.C., "Public Ownership and Irrigation Systems."

R. D. Prittie, superintendent Forestry, Department Natural Resources, C.P.R., Calgary, "Irrigation as Applied to Forestry."

R. M. Winslow, Provincial Horticulturist, Victoria, B.C., "Some Climatic Conditions Influencing the Duty of Water in British Columbia."

Professor Elliott, Superintendent of Agriculture, Department of Natural Reosurces, C.P.R., Strathmore, Alberta, "Irrigation and Intensive Farming."

F. H. Peters, Commissioner of Irrigation, Dominion Government, Calgary, "The Proper Duty of Water and the Necessary Irrigating Head in Western Canada."

N. E. Webster, with Messrs. Niles and Niles, public accountants, New York, "Irrigation Accounting."

John T. Burns, executive secretary, International Dry Farming Congress, Lethbridge, Alberta.

Dr. Samuel Fortier, chief of irrigation investigations, Experimental Station Branch, United States Department of Agriculture, one of the foremost irrigation experts on the continent, whose advice in connection with administration of water matters in British Columbia has been solicited, will address the convention.

A list of delegates should be sent in to the secretary, P.O. Box 1317, Calgary, as early as possible, which list should contain, in addition to the names, the post office address and occupation of each delegate. Norman S. Rankin, permanent secretary.

OBITUARY.

CECIL B. SMITH, Ma.E.

By the death of Cecil B. Smith, Canada has lost one of her most promising civil engineers; taken suddenly just at the stage when his reputation in the special field of hydro-electric development was being recognized as international.

Mr. Smith was born at Winona, Ont., in 1865, his father, Sylvester Smith, being a respected farmer of Wentworth county. His first education was received at the Collegiate Institute, at Hamilton, whence he went to McGill University. He graduated in 1884, receiving first honors and being awarded the Governor-General's medal.

He at once entered on his chosen field in which he was to achieve such distinction. Beginning with railway work as resident engineer on the Northern and Pacific Junction of Ontario (now a section of the C.P.R.) he took work on the construction of the St. Catharines and Niagara Central Railway, and then, attracting the attention of the late W. T. Jennings, was offered work on the C.P.R. at London, Ont. He was next appointed locating engineer of the Toronto, Hamilton and Buffalo Railway in 1888-9. Having in the meantime done some work on the Welland Canal, under the late Thomas Munro, and on the Montreal harbor works under John Kennedy, Mr. Smith sought a wider field of railway experience in the United States, where, between 1889-93 he was divisional engineer of the C.C. & C.R. of Tennessee; chief assistant engineer of the Roanoke Southern Railway of North Carolina, and assistant engineer of the Baltimore and Ohio, in charge of construction, at Morganstown, West Virginia. Returning to Canada in 1893, he was appointed assistant professor of civil engineering at McGill University, being a lecturer on engineering and having charge of cement testing and strength of materials. In the following year he received the degree of Master of Engineering, and in 1895 he began a series of articles on railway work in *The Canadian Engineer*. These articles were in such request that they were reprinted in book form in 1899, under the title "Railway Engineering." This work won immediate recognition by being adopted as a text book in various universities and technical colleges in Canada and the United States. Mr. Smith's ambition could not be confined within college walls, and in 1899 he came to Toronto as assistant city engineer in charge of the sewage system. In 1901 he entered the hydro-electric field, having been appointed construction engineer of the Canadian Niagara Power Co., then one of the three greatest power installations of America. His clear insight into the problem of electric power and its distribution for public use led him to outline plans which, through the courage of Hon. Adam Beck, brought about in later years the Hydro-Electric Commission, which made Ontario the pioneer in legislative experiments in electric transmission. Mr. Smith himself became chief engineer of the Hydro-Electric Commission, and, though not personally in favor of the whole programme afterwards carried out, was a member of the commission through which electrical power was furnished to municipalities in Ontario under government auspices.

Upon the defeat of the Ross Government *The Canadian Engineer*, joined by many men of practical experience, advocated the abolition of political appointments in the control of the Ontario Government railways, and Mr. Smith was happily appointed to take charge of the Temiskaming and Northern Ontario Railway. Here his grasp of problems of railway operation, as well as of construction, were demonstrated, and he soon brought order out of confusion and established this road as the first profit-making government railway in Canada. In 1905 he was appointed chairman of the commission formed to manage this line, and held the post till 1907.

Mr. Smith's services were now in wide demand in hydro-electric work, and he was chosen by the council of Winnipeg to lay out the 60,000 horse-power transmission plant for that city. Having in the meantime formed the engineering firm of Smith, Kerry and Chace, Toronto, he and his associates laid out and, in some cases, financially organized various power plants, among which may be mentioned the Trenton Power Co., the Seymour Power Co., Sydney Power Co., Nipissing Power Co., British Canadian Power Co., supplying power to mines in Cobalt region; the Calgary Power Co., the municipal power plants at Lethbridge and Revelstoke, and other places. He also organized the Mount Hood Railway and Power Co., of Portland, Ore., of which he was general manager and vice-president; and the Crane Falls Power and Irrigation Co., of which he was president, and by which a great tract of heretofore arid land in Idaho is now being converted into a garden by irrigation, while urban comforts are distributed through the new settlement by electricity. Mr. Smith was managing director of the Calgary Power Co., and president of the Nipissing Power Co., as well as a director of other companies.

He was a member of the Institution of Civil Engineers of Great Britain, and a member of the American Society of Civil Engineers. He was a past vice-president of the Canadian Society of Civil Engineers, and among his contributions to this society was a paper describing the Canadian Niagara Power Co.'s plant, which was awarded the Czowski medal of the society. Mr. Smith was not a voluminous participant in the discussions of the society, but his contributions were marked for their pertinence, simplicity of language and clearness of statement. He was president of the Engineers' Club of Toronto, but did not seek the presidency of the society as he held that such honors should be reserved for the elders of the profession.

The Late Cecil B. Smith, Ma.E.

In 1887 Mr. Smith married Miss Mary M. Dempsey, of Hamilton, whose grandfather was the first settler at Milton, Ont., in 1818. He is survived by his widow and two sons, now growing to manhood. His only brother is Mr. E. D. Smith, formerly M.P. for South Wentworth, who has attained a distinction in the Canadian fruit industry corresponding to that of his brother in the engineering field. Mr. Smith leaves also four sisters, Mrs. Shortt, wife of Dr. Adam Shortt, chairman of the Civil Service Commission, Ottawa; Mrs. H. Coon, Weston, and the Misses Gertrude and Violet Smith, of Hamilton.

Mr. Smith's death was comparatively sudden. During the last year or two he had complained of internal pains, but they did not affect his work till, on a trip to the Pacific Coast three weeks before his death, he was taken ill at Los Angeles and a specialist being consulted his malady was pronounced to be cancer and the specialist warned him that an operation would be fatal, as the cancer had invaded the liver and almost completely blocked up the stomach. On his return to his home in Toronto the best medical advice was sought but no hope could be held out that human skill would avail to prolong his life. Thus, a man in the very zenith of his intellectual powers, on the threshold of a world-wide fame, is cut down when the prizes of life are all within his grasp—an event that must humble the ambitious, and leave the mind in awe of the mysterious dispensations of Providence.

COMING MEETINGS.

THE WESTERN CANADA IRRIGATION ASSOCIATION.—Sixth Annual Convention Kelowna, Okanagan Valley, B.C., August 13, 14, 15 and 16, 1912. Secretary, Normon S. Rankin, P.O. Box 1317, Calgary, Alta.

THE UNION OF CANADIAN MUNICIPALITIES.—August 27, 28 and 29. Meeting at City Hall, Windsor, Ont. Hon. Secretary-Treasurer, W. D. Lighthall, K.C.

CANADIAN FORESTRY ASSOCIATION.—Convention will be held in Victoria, B.C., Sept. 4th-6th. Secy., James Lawler, Canadian Building, Ottawa.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Second Annual Meeting to be held in Toronto, Sept. 16, 17 and 18.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Annual Assembly will be held at Ottawa, in the Public Library, on 7th October, 1912. Hon. Sec'y, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

EIGHTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.—Opening Meeting, Washington, D.C., September 4th, 1912. Other meetings, Business and Scientific, in New York, beginning Friday, September 6th, 1912 and ending September 13th, 1912. Secretary, Bernhard G. Hesse, Ph. D., 25 Broad Street, New York City.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, W. Alan, Kennedy; Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-jack. Meets every first and third Friday of each month, October to April, in [illegible]

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION.—President, Mayor Lees, Hamilton, Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. Secy.-Treasurer, John T. Moore, Red Deer, Alta.

THE UNION OF CANADIAN MUNICIPALITIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., ex-Mayor, Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer, J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secretary, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, Mayor Mitchell, Calgary; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy.-Treasurer, Reeve Cardale, Oak Lake, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewit, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President, J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Jas. Anderson, Gen. Mgr., Sandwich, Windsor and Amherst Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman; Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Hon. W. R. Ross, Minister of Lands, B.C. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phoenix Block, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg

Volume 23 Toronto, July 18, 1912

The Canadian Engineer

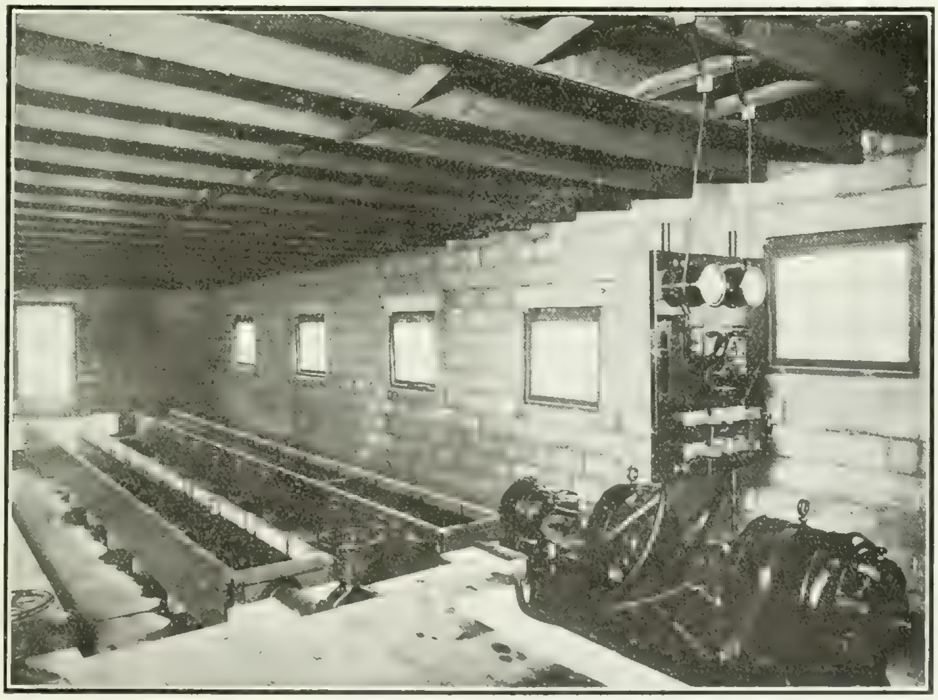
An Engineering Weekly

AN ELECTRICAL SEWAGE DISPOSAL PLANT.

By C. L. EDHOLM, Los Angeles, Cal.

In order to render odorless and innocuous the sewage of a city, a system has been perfected for treating it by the electrolytic process, at slight expense and with complete success. Two such plants are in operation in the West, and a third, of three times the capacity, is being constructed at a cost of $45,000, so that the device is no longer in the experimental stage. These plants may be seen in service at Santa Monica, near Los Angeles, California, and in Oklahoma City, and in the latter town a second plant was ordered after a thorough trial of the one now operating.

The purifying of water by electrolysis has been known for some time, but it was only in late years that experiments were successfully made with the view of destroying the disease germs in sewage and eliminating offensive odor by the use of electrodes.



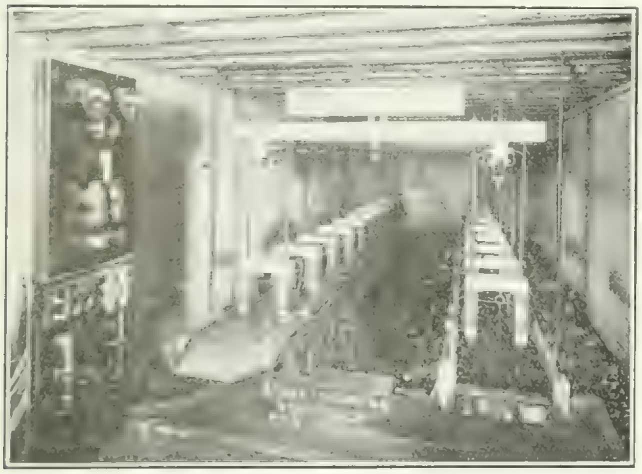
Interior of Oklahoma City Plant.

The process may be described briefly as follows: The raw sewage is allowed to flow through wooden flumes having a length of thirty feet, width of 22 inches and depth of 18 inches. Ten sets of electrodes are placed in each flume, being composed of cast iron plates set half an inch apart and having the dimensions of nine inches by 24 inches, and a thickness of 3/16th of an inch. These electrodes receive a current of two to three volts and seven to eight hundred amperes, and as the sewage flows slowly through the flumes it is speedily purified. The odor is instantly "killed," so that there is no offence to the nostrils, even to one standing directly over the flumes. But this is not all, the liquid is clarified as well and practically all the germs are destroyed, preventing further putrefaction and making it possible to discharge the sewage into a river or upon land for irrigation purposes without danger to health. This is not a case of the germs being electrocuted, but is due to chemical changes brought about by the decomposition of the metal in the electrodes. Just how this is done has been determined by chemical analysis, but the results are plain to the most casual observer.

The electrical equipment of the Oklahoma City plant is described by Howard V. Hinkley, consulting and supervising engineer, as follows: "The drive consists of a 7½ h.p. alternating current motor using commercial current at 220 volts. This motor is direct connected, under the switchboard, to a 3 kw. multipolar direct current generator and exciter, all resting on a single bedplate 2 x 5 feet. The combination is designed and built for this special service and delivers to the copper cable conductors of 1,000,000 circular mills 800 to 900 amperes at a voltage of 1½ to 3, these being the limit between which the desired results are obtainable, varying somewhat with the character of the sewage. A double pole, double throw knife switch allows the reversal of the current at pleasure and a knife switch at the upper end of each flume cuts on or off the current for that flume. Owing to the high amperage as compared to the low voltage the switches and conductors are necessarily heavy. If only one flume is used the ammeter is set at 270 or 300."

The Santa Monica plant has in addition a centrifugal pump, which is operated by electricity, and used for raising the sewage from a reservoir to the level of the flumes, but this is caused by local topographical conditions, as elsewhere it might be convenient to construct the plant on a lower level than the basin.

The cost of current will vary in different cities, but the electrodes need but little (the bill for an entire year at Santa Monica was only $152.95) and the expense of repairs and replacement of plates is slight. One attendant can care for the plant, or even two or three if they were conveniently located for going back and forth between them, as they require hardly any work.



Santa Monica Plant, as Originally Built. The Magnets Over the Flumes Have Since Been Discarded and Another Flume Added.

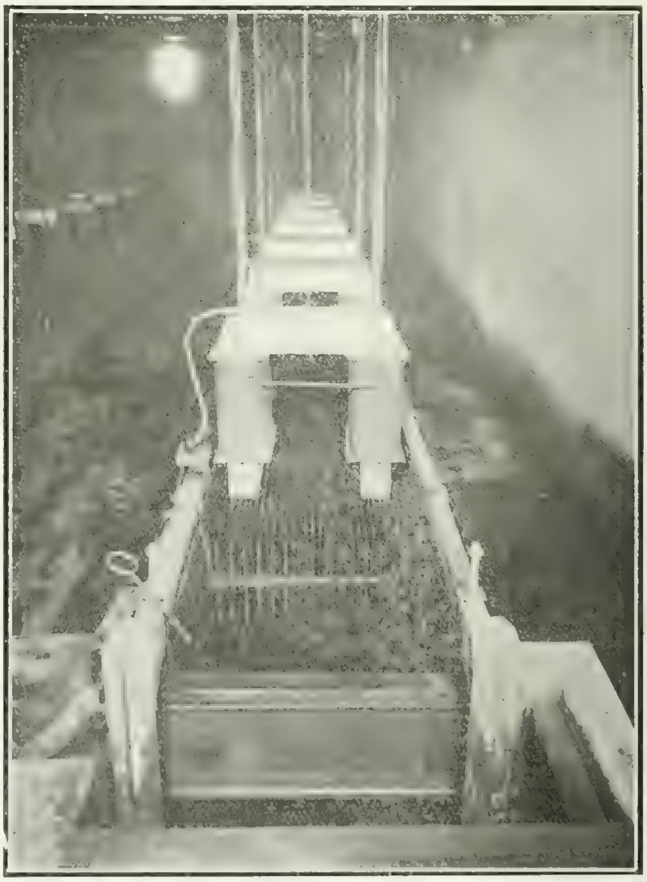
Cleaning of the plates is done by means of reversal of the current, while the use of a garden hose a few minutes each day cleans out the flumes and washes off the plates.

Very limited space is sufficient to house such a plant. In Oklahoma City a building 18 x 50 feet and 10½ feet high encloses a system of three flumes that handles three-quarters of a million gallons a day. In Santa Monica [illegible]

Interior Oklahoma City Plant, Showing Electrodes in Empty Flume, and Flow in Another.

raw sewage discharged into the ocean. Protests were heard at once from visitors and residents, but when it started again, all complaints ceased. In Oklahoma the conditions were quite different, as the outfall was in a dry gulch which was shunned and its vicinity rendered useless for any purpose. Now that the discharge has been electrolytically treated, the air is not contaminated. In fact such water could be used for irrigation and its great proportion of fertilizing content put to good use.

The two plants described can be reproduced for $15,000 each. Many costly features have been eliminated since the first one was installed. The heavy and expensive magnets, once considered necessary, have been discarded, and an elaborate system of cleaning the electrodes by high pressure steam was abandoned when it was found that the reversal of the current would give better results. The cost of the plates has been greatly reduced, by the substitution of cast iron for the aluminum which was first tried. The aluminum plates gave good results, but they were very costly and decomposed so rapidly that their expense was prohibitive. The cast iron [illegible] and by [illegible] the upper edge of the plates with copper, excessive decomposition was prevented.



Electrodes in Place, Santa Monica Plant. The Heavy Magnets Have Now Been Discarded, Reducing Expense.

Aside from its sanitary importance, this novel use of the electric current may add materially to the world's wealth in saving the millions of tons of valuable fertilizer that are [illegible] into the [illegible] each year. Thoughtful men have deplored this waste, and many years ago Victor Hugo, in writing a description of the sewers of Paris, referred to such [illegible]. In some parts of Germany and in China, the soil is so depleted that raw sewage is used [illegible] to renew the exhausted land. By the modern method it may be treated and used on fields, [illegible] their value and being an [illegible] of a menace to health.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only, unless otherwise noted, at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close			Noted in issue of
7-10	Supply of electrical machinery and sewage disposal works, Battleford, Sask.	(P. & S.)	6-27
7-20	—Concrete Arch, Stratford, Ont.	(P. & S.)	7-4
7-20	Concrete work on bridge and dam at Georgetown, Ont.	(P. & S.)	7-11.

(Battleford plans and specifications are also on file at The Canadian Engineer Offices, Montreal and Winnipeg.)

TENDERS.

Calgary, Alta.—Tenders for the construction of three reinforced concrete bridges, aggregating some 25 spans, across the Bow and Elbow Rivers, within the city limits of Calgary, will be received until July 31st, 1912. Plans and specifications can be seen at the office of the City Engineer in Calgary. J. M. Miller, City Clerk.

Clan William, Man.—Tenders for the erection of a two-roomed brick veneer school building for Grey, S.D. 1356, will be received until July 15th, 1912, by R. A. McQuarrie, Secretary-Treasurer, Grey S.D., 1356, Clan William, Man. Plans and specifications may be seen at the office of the Architect, W. W. Blair, 400-2 Nanton Building, Winnipeg.

Edmonton, Alta.—Tenders for all trades in connection with the erection and completion of the Civic Office Building at the corner of Queen's Avenue and Elizabeth Street, Edmonton, will be received until July 15th, 1912, by the City Commissioners. Plans, etc., at the office of the City Architect, Johnson Block, Second Street, Edmonton.

Estevan, Sask.—Tenders will be received until noon of July 16th, for the erection and completion of a four-roomed public school at Estevan. Plans and specifications at the office of Messrs. Storey and Van Egmond, architects, Regina, Sask., and the office of L. A. Duncan, Secretary-Treasurer, Public School Board, Estevan, Sask.

Guelph, Ont.—The time for receiving tenders for the concrete work for the combined bridge and dam at the Paper Mills, Georgetown, has been extended to noon of July 20th. Jas. Hutcheon, Engineer, Guelph (See advt. in The Canadian Engineer.)

Hamilton, Ont.—Tenders will be received by the Mayor, Chairman Board of Control, up to July 15th, for the following trades required in the erection of a Children's Hospital on the City Hospital grounds, Barton Street, Hamilton. Mason and brickwork, reinforced concrete, carpenter work, painting, plumbing, steam heating, iron work, plastering, electric wiring, galvanized iron and roofing, ceramic tiling, sewer work. Plans and specifications to be seen at the office of H. H. New, Architect, Spectator Building. S. H. Kent, City Clerk, Hamilton.

Hamilton, Ont.—Tenders for supplying the corporation of the city of Hamilton with four units of synchronous motors for direct connection to turbine pumps, with switching apparatus and accessories complete, for the High Level and Mountain pumping systems, will be received by G. H. Lees, Mayor, Chairman Board of Control, Hamilton, until noon of July 24th, 1912. Specifications at the office of the City Engineer. S. H. Kent, City Clerk. (See advt. in The Canadian Engineer.)

Islington, Ont.—Tenders will be received up to noon of July 23rd, for the construction of a 24-inch storm sewer, about 1,040 feet in length with manholes, catch basins and junctions, on Plan No. 1602, County York, near the village of Islington. Plans, etc., at the office of J. A. L. Macpherson, Engineer, Islington.

Kingston, Ont.—Tenders will be received until July 16th, 1912, for the construction of 7,200 square yards of asphalt block or vitrified brick pavement and 3,000 lineal feet concrete curb. Plans and specifications may be seen at the office of R. J. McClelland, City Engineer, Kingston.

Lasalle, Que.—Tenders for the construction of an aqueduct in the town of Lasalle, will be received by J. S. Ashby, Secretary-Treasurer, town of Lasalle, until July 17th, 1912. Plans and specifications can be seen at the office of V. H. Dupont, Town Engineer, 62 St. James Street, Montreal, or at the office of the Secretary-Treasurer.

Medicine Hat, Alta.—Tenders are called for the erection of a 5-room brick school building for the Medicine Hat School District No. 76. Tenders close July 15th. Plans and specifications may be seen at the office of the architect in the Porter Block, Medicine Hat, Alta. R. M. Napier, Secretary, Medicine Hat School District No. 76.

New Westminster, B.C.—Tenders for paving eight streets in the city of New Westminster, B.C., will be received until July 15th. Plans and specifications and full particulars can be obtained from J. W. B. Blackman, City Engineer. W. A. Duncan, City Clerk, City Hall, New Westminster.

Ottawa, Ont.—Tenders for the construction of a landing pier at Ste. Felicite, County of Rimouski, Que., will be received at the Department of Public Works, Ottawa, until July 31st, 1912. Plans, etc., at the Department, the offices of A. R. Decary, Esq., District Engineer, Post Office Building, Quebec. J. A. Tremblay, Esq., District Engineer, Montmagny, P.Q., and on application to the Postmaster at Ste. Felicite, Que.

Ottawa, Ont—Tenders for dredging required at River Bourgeois, N. S., will be received until July 30th, at the Department of Public Works, Ottawa. Specifications, etc., at the office of the Secretary, Department of Public Works, Ottawa.

Ottawa, Ont.—The Department of Indian Affairs, Ottawa, is open to receive tenders for the erection of a boarding school building on the Pas Reserve on the Saskatchewan River, up to noon of August 19th, 1912.

Ottawa, Ont.—Tenders for the erection of an Indian boarding school and a hospital at Norway House, Man., will be received up to noon of August 19th, 1912. Separate tenders for each building must be submitted. Plans, etc., may be seen at the Indian office, Winnipeg; the office of the Indian Agents at Selkirk and Portage La Prairie; the office of the Agent of Dominion Lands, Brandon and the Post Office, Kenora. J. D. McLean, Assistant Deputy and Secretary, Department of Indian Affairs, Ottawa.

Ottawa, Ont.—The Department of Public Works, Ottawa, is open to receive tenders until July 24th, for the construction of a wharf at Boisdale, Cape Breton County, N.S. Plans, etc., at the Department, also at the offices of G. A. Bernasconi, Esq., District Engineer, North Sydney, N.S.; C. E. W. Dodwell, Esq., District Engineer, Halifax, N.S.; and the Postmaster at Boisdale, N.S.

Ottawa, Ont.—Tenders for the construction of a model and gun shed at Royal Military College, Kingston, Ont., will be received until noon of July 20th. Specifications, etc., may be seen at the office of the Officer Commanding the No. 3 Divisional Area and the Commandant Royal Military College, Kingston, Ont., and of the Director of Engineer Services, Headquarters, Ottawa. [illegible], Acting Deputy Minister, Department of Militia and Defence, Ottawa.

Ottawa, Ont.—The Department of Public Works will receive tenders until July [illegible], for the construction of a wharf and approach at the town of Orillia, Simcoe County, Ont. Plans, etc., can be [illegible] at the office of J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto, and on application to the Postmaster at Orillia.

Ottawa, Ont.—[illegible] will be received until July [illegible], at the office of the Secretary of the Department of Public Works, Ottawa. [illegible] District Engineer, [illegible] District Engineer, [illegible] and on application to the Postmaster at Seaforth, N.S.

Ottawa, Ont.—Tenders for dredging required at Arnold's Cove, Halifax County, N.S., will be received until July 17th, 1912. Specifications, etc., at the office of the Secretary, Department of Public Works, Ottawa. R. C. Desrochers, Secretary.

Regina, Sask.—Tenders for the erection of a court house building at Yorkton, Sask., will be received up to noon of July 20th, 1912. Plans, etc., at the office of the Yorkton Times, the Builders' Exchange, Winnipeg, and the office of H. S. Carpenter, Acting Deputy Minister, Department of Public Works, Regina.

Swift Current, Sask.—Tenders for cement concrete curbing, sidewalks and crossings, will be received until July 16th, 1912. Geo. D. Mackie, Town Engineer. (See advt. in The Canadian Engineer.)

Toronto, Ont.—Tenders will be received at the Department of Public Works up to noon of July 19th, for building lighting area, roadways, cement walks and iron fences on the grounds to the north of Osgoode Hall, Toronto. Plans and specifications at the Department. H. F. McNaughten, Secretary, Department of Public Works, Ontario, Toronto.

Toronto, Ont.—Tenders wanted on railroad contract. 12,000 cubic yards earth excavation. Plans and specifications at office. Toronto and York Radial Railway, Toronto.

Welland, Ont.—Tenders are invited for the building of one large concrete arch over Lyons Creek and several smaller ones. Description, etc., may be had at the office of Reeve O. A. McKenney, H. L. Pratt, Township Clerk.

Winnipeg, Man.—Tenders for the supply of a quantity of water meters will be received up to noon of July 18th, 1912, by M. Peterson, Secretary, Board of Control Office, Winnipeg.

Winnipeg, Man.—Tenders for plank sidewalks, grading, or gravelling, will be received up to noon of July 16th, 1912. Full particulars may be obtained from D. R. Baribault, Municipal Engineer, 607 Builders' Exchange. Chas. J. Drake, Clerk, Rural Municipality of Fort Garry.

◆

CONTRACTS AWARDED.

Hamilton, Ont.—The Canadian Westinghouse Company, Limited, has secured a contract from the Shawinigan Water and Power Company, Shawinigan Falls, Que., for one 15,000 K.W. 2-bearing water-wheel type, 60 cycle generator, which is the largest water-wheel generator to be installed in Canada. This will be the third unit which the Westinghouse Company will have furnished from their Hamilton Shops for the new power house of the Shawinigan Company, the other two units being of slightly smaller capacity, viz., 14,000 K.W.

Montreal, Que.—The position of consulting engineer for the new technical school was awarded to the Canadian Domestic Engineering Company of Montreal. There were twelve applications, but the Montreal firm was highly recommended.

Ottawa, Ont.—The contract for the construction of the new treasury vaults to be installed in the recently completed extension to the finance department in the east block goes to the Goldie and McCulloch Company, of Galt. The undertaking is of considerable magnitude, the estimated cost of the vaults being in the neighborhood of $[illegible].

Winnipeg, Man.—Messrs. Worswick Bros., have the contract for the erection of a $150,000 school building. J. B. Mitchell, commissioner of Winnipeg schools, is the architect.

Winnipeg, Man.—Messrs. Laing Limited, are building a four storey brick warehouse costing $[illegible]. F. J. Green [illegible] is the architect and Carter-Hall-Aldinger Company, Limited, the contractor.

$Dolarway
Pavement

"It is permanent because it is concrete."

The Last Word
In Street Pavements

The Dolarway Pavement is popular with City Officials, Highway Engineers and Property Owners because:

It is low in first cost.
Its maintenance cost is lower than that for any other permanent form of Pavement.
No paving plant is required to either construct or maintain it.
It is noiseless, dustless and resilient.
Its traction qualities for both the Horse and the Automobile are of the best.

Applying Dolarway Bitumen on Concrete Base, Central Park, N.Y. City.

RAILWAYS—STEAM AND ELECTRIC.

Montreal, Que.—An electric railway between Ottawa and Kingston, is being promoted by Mr. T. R. Clougher, of London, England. A bond issue will shortly be placed in England to finance the road.

New Westminster, B.C.—The harbor by-law has been approved by the citizens. Mr. A. O. Powell, is the engineer who has prepared the plans and he will have charge of the work.

Prescott, Ont.—It is announced that the Grand Trunk Railway shops and roundhouse at present located in Brockville will be moved to Prescott in the immediate future.

Sault Ste. Marie, Ont.—The Algoma Central and Hudson Bay Railway has finished laying steel between the Sault Ste. Marie and Hobon Station. The ballasting, however, will not be complete for some months.

Toronto, Ont.—It is reported that the Grand Trunk Railway will organize a subsidiary warehousing company to relieve the freight congestion in Toronto yards.

◆

LIGHT, HEAT AND POWER

Kingston, Ont.—Mr. R. S. Kelch, Consulting Engineer, Montreal, has advised that the city add to its present steam plant to secure increased capacity. It will be remembered that the Ontario Hydro-Electric Commission and the Electric Power Company, Limited, have been competing for the new business. The Civic Utilities Committee of the City Council has decided to follow the advice and will proceed with the ordering of additional machinery for the necessary extensions to the plant.

Kingston, Ont.—Mr. R. S. Kelch, in a report to the municipal council of this city advises that the city's present steam plant, with certain additions, can take care for a number of years of the local demand for power, and can furnish it cheaper than it could if it took the supply from the Commission or the Seymour Company. Mr. Kelch's report will be adopted by the City Council, and his recommendation to the steam plant will be made this year.

New Westminster, B.C.—In a short time, the question of the installation of a municipal gas plant will be taken up, as soon as litigation pending is settled. A by-law has been passed giving the necessary authority to the city council.

Ottawa, Ont.—At a conference here July 3rd attended by Hon. Adam Beck, representing the Ontario Hydro-Electric Commission; Hon. S. N. Parent, Chairman of the Quebec Commission on running waters; and J. A. Ellis, M.L.A., representing the city of Ottawa, the question of joint development of the Chats Falls power on the Ottawa River was considered. It was decided to instruct the engineers of both the Ontario and Quebec Commissions to [illegible]

Province of Ontario.—The Ontario Hydro-Electric Commission has issued instructions to its engineers to survey [illegible] for a transmission line to furnish power to Collingwood, Coldwater and Barrie. The big chute plant of the Simcoe Power Company will furnish power. Mr. P. W. Sothmann, Toronto, is the chief engineer [illegible]

Tofield, Alta.—The ratepayers will vote on expending [illegible] throughout the municipality. Should the ratepayers vote in favor Mr. Elder will [illegible]

Welland, Ont. [illegible]

◆

Walter Sangwin, [illegible]

GARBAGE, SEWAGE AND WATER.

New Westminster, B.C.—The city has just passed a by-law to provide funds for the improvement of the waterworks system. Mr. J. W. B. Blackman is the City Engineer.

New Westminster, B.C.—No time is being lost in making a start on the harbor improvements for which ratepayers expressed themselves in favor of voting half a million dollars. Preliminary work on the scheme is to commence at once, and it is expected that an actual start can be made on the temporary piling for the concrete work by next September. Mr. G. A. Powell, of Seattle, is the engineer in charge.

◆

BUILDINGS AND INDUSTRIAL WORKS.

Blair, Que.—The Dominion Government, Department of Militia and Defence, Ottawa, contemplate the erection of an up-to-date military school.

Edmonton, Alta.—Plans have been prepared and work will commence shortly on the erection of a large business block in this city. The block will be built by Kenneth A. McLeod, the architect is John R. Dow. Estimated cost of building, $500,000.

Fort William, Ont.—Work will be started shortly on the big government elevator to be erected here. It is understood that the capacity of the elevator will be 3,250,000 bushels.

Montreal, Que.—Plans are being laid for the construction of a mammoth new department store at the corner of St. Catherine and Bleury Streets. It is reported that the Scroggie firm are interested.

Port Arthur, Ont.—The new Roman Catholic Cathedral will be situated on the corner of Algoma and Arthur Streets. It is to cost $[illegible].

Port Arthur, Ont.—The municipal engineer, L. M. Jones and staff will proceed with the building of the civic market.

Prince Albert, Sask.—The municipal council will erect a police station at a cost of $[illegible].

Sherbrooke, Que.—The Board of School Commissioners contemplate the erection of a new high school building.

St. John, N.B.—General Manager McNicoll, of the Canadian Pacific Railway, stated last week that the plans for the company's new million bushel elevator at St. John had been completed and that the contract for its erection would be given very soon.

Thorold, Ont.—The Montrose Paper Mills Company, Limited, intend building another paper mill at Thorold, Ontario. They have ordered practically all the necessary machinery. The building will cost $100,000.

Toronto, Ont.—The swift Canadian and the Harrris Abattoir Companies will erect a large tannery at West Toronto.

Toronto, Ont.—A new civic abattoir will in all probability be [illegible] erected. The cost will be about $200,000. Alderman O'Neil is pressing the matter in the City Council.

Vancouver, B.C.—A reinforced concrete, six-story rooming house will be erected on Pender Street. The structure is being built for Mr. John Walker by Mr. F. J. Langer, after plans prepared by Messrs. Braunton and Leibert, architects of Vancouver. Cost of building will be over $[illegible].

Vancouver, B.C.—The Norton Griffiths Steel Company are erecting a six-story reinforced concrete, brick faced, stone dressed warehouse building for Messrs. Crane and Company. Estimated cost, $[illegible].

Vancouver, B.C.—Work will be started shortly on the new Y.M.C.A. building. Estimated cost, $350,000.

BRIDGES, ROADS AND PAVEMENTS.

Coboconk, Ont.—The plans for five new culverts for the Township of Bexley are under consideration. A. Taylor, Clerk.

London, Ont.—City Engineer Wright has reported to the Board of Works that $25,000, the amount voted on, is not sufficient to build West London bridge, that $45,000 is needed to construct a proper bridge, and at least $20,000 more will have to be voted on.

New Westminster, B.C.—A great deal of street paving is to be done here. Many by-laws are being submitted on the question now. J. W. B. Blackman, is City Engineer.

Pointe Claire, Que.—The town contemplates the laying of cement sidewalks, renovating the river front from Lachine to Ste. Anne, and establishing boulevards and driveways.

Niagara Falls, Ont.—The Grand Trunk Railway Company propose to replace the wooden bridge on Victoria Avenue, by a steel one.

Saskatoon, Sask.—Arrangements have just been completed with the City Council for a new traffic bridge over the river, which will also provide accommodation for a double line of street cars.

North Vancouver, B.C.—The passing of the district of North Vancouver's $150,000 by-law will give cities and municipalities interested control of the Burrard Inlet Tunnel and Second Narrows Bridge Company.

Simcoe County, Ont.—Plans are now being prepared for five new bridges to be built this summer; one of these is to be of the concrete truss type, and will be located near the village of Nottawa, near Collingwood. The other four will be steel structures. Mr. Frank Barber, 57 Adelaide Street East, Toronto, is consulting engineer.

Vancouver, B.C.—For the construction of the proposed Georgia-Harris Street Bridge, plans from nine engineering firms were examined by the bridges and railway committee of the city council.

All the designs were referred to the city engineer to report. The bridge is to be 2,740 feet in length, and it is expected that the work could be completed in about eighteen months. The designs were from the following:

Cartwright and Matheson, Vancouver, $611,000; steel.

Waddell and Harrington, Vancouver, $510,000 (two plans, both in regard to steel construction); another plan, $508,000, steel; and a fourth plan at $524,000, reinforced concrete.

E. A. Stone, Vancouver, $514,000, with a plank surface, and $521,000, with creosoted wood blocks on the surface, steel.

C. A. P. Turner, Winnipeg, $404,950 (with deck span), and $504,950, reinforced concrete.

Gardner and Taylor, Vancouver, $539,730, concrete.

H. Sydney Hancock, Vancouver, $500,000, concrete.

Dutcher, Maxwell and Company, Vancouver, $442,938, concrete.

[illegible], Vancouver, $[illegible], steel.

Van Sielen and Macomber, Vancouver, sent in plans, [illegible]. The designs were for both [illegible] and concrete.

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the Office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending June 24th, 1912. Additional information may be obtained from the Department of Trade and Commerce, Ottawa.

A Liverpool firm of sack manufacturers desire to get into touch with importers and users at Montreal, Vancouver and other ports in Canada.

A London firm makes inquiry for the names of Canadian exporters of Canadian birch wood ready cut up for use in the manufacture of hammock chairs, etc.

From the branch for City Trade Inquiries, 73 Basinghall Street, E.C.

A London firm is open to purchase upon a cash basis supplies of best white beech dowels, cut to specification, and invites quotations from Canadian manufacturers. They are also buyers of maple mangle rollers.

A North Country manufacturer of paraffin and crude oil engines desires to arrange for their sale in Canada.

A Lancashire firm manufacturing contractors' and engineers' supplies, also rails, switches and crossings, are open to appoint suitable Canadian resident agents.

◆

PATENTS.

The following is a list of patents recently granted to inventors in Canada. The list is furnished by Messrs. Fetherstonhaugh and Company, Patent Barristers, Solicitors, etc., 10 King Street East, Toronto.

T. M. Kirkwood, railway rails, B. F. Osbow and F. C. Mason, tube retarders, J. H. Rodgers and W. J. Spence, tripping device for power presses and analagous machines, J. P. Beaudoin, railway signal torpedoes, J. A. Bergmann, illuminated signs, C. F. Broadhurst, means for clearing chimney flues, I. E. Cornwall, gramaphones, O. R. Johnston, grain picklers, A. Mackay, necktie formers, E. Richard, steam valve mechanisms, J. F. Ross, cans, J. R. Saye, multiple duplicating check books, F. X. O. Trudel, food products and processes of obtaining the same.

◆

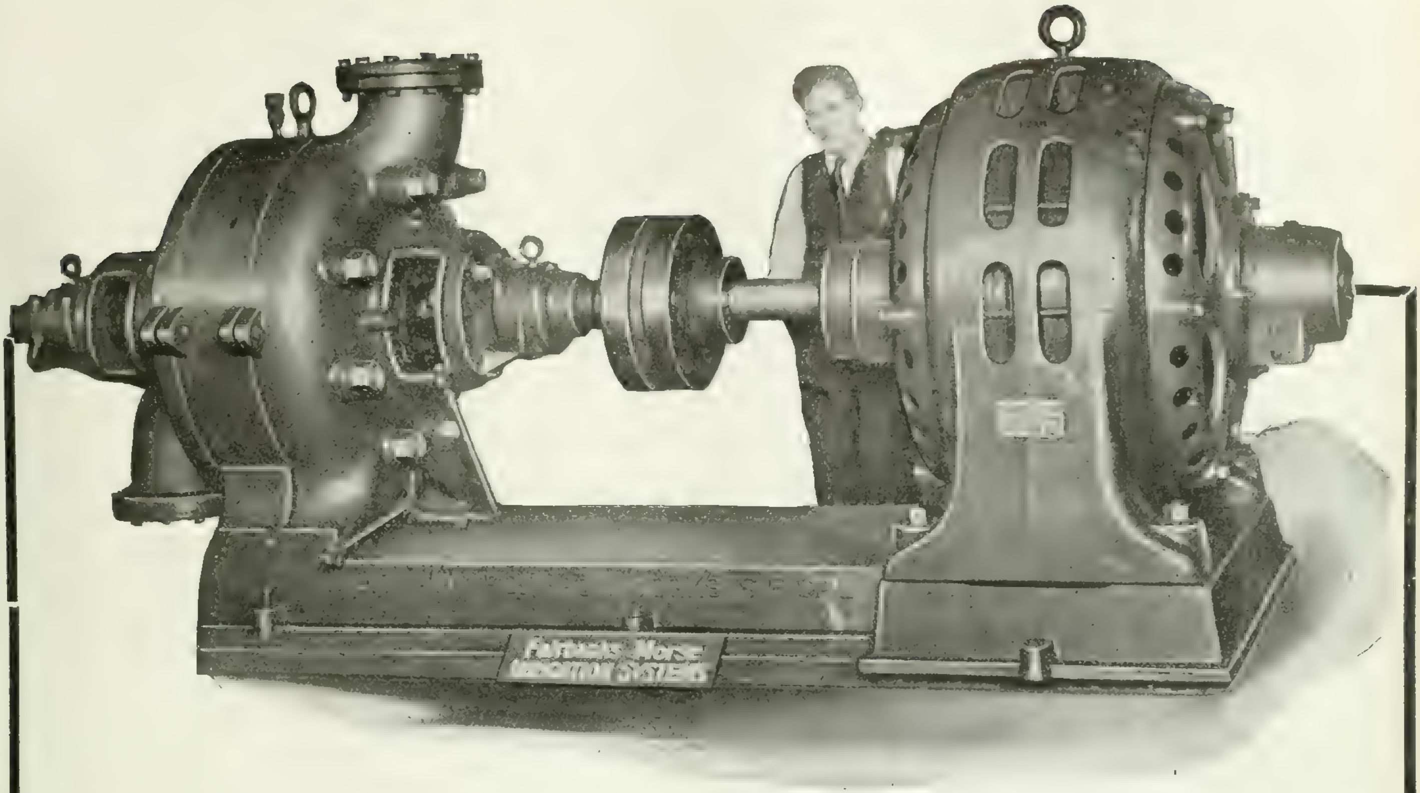
LOSSES CAUSED BY ENGINE SPARKS.

A heavy loss by fire each year is caused by sparks from locomotives. The United States district forester for Montana and Idaho estimated a loss to government and adjoining timber of 6,000,000,000 feet, or a total of $21,500,000, caused by 1,679 fires, 56 per cent. of which started on the railroad rights-of-way and in spite of good co-operation by the railroads.

The great forest fires in Minnesota during 1910, which caused such loss of life and suffering in the towns of Spooner and Beaudette, with a million dollars worth of valuable property and timber, were due to four fires, three of which were started by locomotive sparks.

Four fire insurance companies which make a specialty of insuring flour mills and elevators paid more than $160,000 in 1910 for losses due to this cause. The Cotton Insurance Association if Georgia has reported that 90 per cent. of cotton fires in transportation are due to locomotive sparks. A grain dealers' mutual fire insurance company reports each year from 17 to 28 per cent. of its losses due to the same cause.

The fire records of manufacturing risks which have been published in the quarterlies of the National Fire Protection Association show a very material percentage of fires from locomotive sparks, and yet, taken as a whole, we would not consider manufacturing risks as particularly susceptible to the spark hazard. The record of fires in 15 classes of manufacturing risks showed about 3 per cent. to be due to this cause.



The Largest Direct Connected Centrifugal Pumping Unit in British Columbia.

The Vancouver Power Company have recently installed at their works at Coquitlam Dam, B.C., the largest direct connected centrifugal pumping unit in British Columbia. This outfit is to operate in parallel with a number of other pumps that are to furnish water under pressure for sluicing into place the material for their new dam.

This pump is a 10-inch, class "F," two-stage centrifugal, with bronze inpellers and renewable bronze diffusion vanes. It has a normal capacity of 1833 imperial gallons per minute when operating at 1160 r.p.m. against a total head of 355 feet or an equivalent pressure of 154 lbs. per square inch. It is mounted on a common sub-base with a 300 h.p. type "B," Fairbanks-Morse squirrel cage, induction motor, 2200 volts, 60-cycle, 3-phase, 1160 r.p.m. at full load, being direct connected thereto by means of a flexible leather link coupling.

The motor possesses a feature in rotor construction that is unique. The end rings are welded on to the rotor bars by a new process, making a perfect joint, free from the troubles common to the purely mechanical or riveted joint, such as oxidation, working loose, and solder-throwing. This improvement marks a long step forward in the elimination of rotor trouble.

Our Vancouver Branch supplied and assembled this complete pumping unit. We are in a position to quote on the necessary equipment for any pumping requirements on receipt of specifications.

UNITED STATES GOVERNMENT HEARING ON FLANGE FITTINGS.

The Navy Department, Bureau of Yards and Docks, Washington, D.C., held a hearing June seventeenth, for the purpose of giving certain manufacturers an opportunity to give reasons why they do not recommend the use of the 1912 United States Specifications on Government work.

The Government had representatives present from the following departments,—Army, Navy, Auditing, Purchasing Department, Bureau of Yards and Docks, Bureau of Standards; the manufacturers represented were:—Crane Company, Walworth Manufacturing Company, McNab and Harlan, Best Manufacturing Company, Kelly and Jones; and the Societies responsible for the 1912 United States Standard were represented by Mr. Henry G. Scott, member of the Council of the American Society of Mechanical Engineers, and Mr. Henry B. Gombers, Secretary of the National Association of Master Steam and Hot Water Fitters. Mr. Carl L. Carlson, Corps of Civil Engineers of the United States Navy, presided.

During the first part of the meeting the manufacturers' representatives, of which Mr. A. M. Hauser, of Crane Company, and Mr. Evans, of Best Manufacturing Company, were the spokesmen, put in their protest against the adoption by the Navy of the 1912 United States Standard. After this, Mr. H. B. Gombers, of the National Association of Master Steam and Hot Water Fitters, replied, outlining the efforts of the committees of the two societies for the past year and a half by conducting extraordinary correspondence with the principal companies manufacturing fittings in America and in every way trying to establish a standard which would best represent the interest of all, which resulted in the 1912 United States Standard. Mr. H. G. Stott, who is Superintendent of Motive Power of the Interborough Rapid Transit Company of New York, presented the desirability of adopting the new standard from the engineering point of view. By making use of a set of temperature and expansion curves the principal points emphasized were that the factor of safety in the ordinary pipe line is from 16 to 20, while the factor of safety in the bolts is two or less, so that everything possible should be done to bring up the factor of safety in the bolts, flanges and fittings, especially in view of the enormous strains encountered due to change in temperature. By comparing the 1912 United States Standard with the proposed Manufacturers' Standard, the British and German Standards, it was shown that the 1912 United States Standard was the heaviest and strongest of all. Another important feature of the 1912 United States Standard was shown to be the interchangeability of parts, where the proposed manufacturers' schedule has different face to face dimensions, and that the changes referred to extra heavy work and to sizes above nine inches only.

The consensus of opinion at the hearing was in favor of the 1912 United States Standard.

The chief objection the manufacturers made was the enormous cost to them. It developed, however, from the testimony of one of the manufacturers present, that the cost of the change to the new standard would be practically very little, because they had already been through the experience [illegible] and the lack of expense was due to the fact that they did not use iron patterns or special tools in their work, but did all their facing on lathes and facing machines.

During the remainder of the hearing the discussion settled [illegible] necessary [illegible] could be supplying material according to the 1912 United States Standard, and the general consensus of opinion seemed to be that within two years the new standard would probably be- [illegible]

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

[illegible]

[illegible]

[illegible]

16872—June 26—Authorizing C.P.R. to open for carriage of traffic its railway from Coldwater, at mileage 12 to Bethany, at mileage 88.2—76 miles, (G. B. & S. Ry.).

16873-74—June 26—Relieving C.P.R. from erecting and maintaining fences on its Boundary, Nakusp & Slocan and Lardo, also Okanagan, Shuswap, Mountain & Arrow Lake S. Divisions.

16875—June 25—Authorizing C.P.R. to construct spur for Alberta Clay Products Co. at Dunmore, Alberta.

16876-77—June 25—Authorizing C.P.R. to construct ballast pit spur across highway near Elcan, Alta., and its Pheasant Hills Branch across highway at mileage 17.3, McAuley S.D.

16878—June 25—Relieving C.P.R. from further protecting crossing at mileage 90.5 from Switzer Jct., Arcola S.D., Manitoba.

16879—June 26—Approving location of C.P.R. station at North Transcona, Manitoba.

16880—June 26—Extending until July 31, 1912, time for installing derails on Union Stock Yards Branch, Toronto, by G.T.R.

16881-82—June 26—Authorizing G.T.R. to construct spurs for Dominion Canners, Ltd., near Forest Station, Ont., and for N. J. and W. G. Smart, near Collingwood, Ontario.

16883—June 25—Approving changes in side track and stockpen of G.T.R. in village of Priceville, Quebec.

16884—June 26—Authorizing G.T.R. to construct spur for Benson & Bray, Midland, Ontario.

16885—June 26—Dismissing application of residents of Druid, Alta., to compel G.T.P. to install station near C.P.R. station, application may be made for transfer track.

16886—June 24—Authorizing G.T.P. Ry. to cross highway at mileage 176.9, Cassair District, British Columbia.

16887—June [illegible]—Authorizing C.N.O. Ry. to cross public road at Cote St. Michel, County of Hochelaga, Que.

16888—June 25, 16889—June 26—Approving revised location of C.N.O Ry. industrial branch from Oshawa station to town of Oshawa, and authorizing it to cross side-road in Twp. of Mara, Ont.

16890—June 26—Approving revised location of Toronto Eastern Ry., Twp. of Pickering, and Ontario.

16891—June 25—Rescinding paragraph 2 of the operative part of Order 15727, dated December 19, 1912, and leave is reserved to G.T.P. Ry. to apply to Board for approval of station site which will give adequate facilities to Hazelton, B.C. Application, Robert Kelly, Vancouver, B.C.

16892—June 27—Amending Order [illegible], by striking out "Montreal Tramways Co." in 8th line of operative part and substituting words "City of Montreal."

16893—June 26—Directing Dominion Atlantic Ry. to show cause within 10 days why it should not furnish at Kentville, N.S., adequate and suitable facilities for housing and repairing of its engines and cars under penalty of $25 per day.

16894—June 26—Authorizing Mun. of County of Compton, Que. to construct highway crossing over Maine Central Ry.

16895—June 25—Authorizing J. B. Damphouse, of Stony Point, Ont., to construct farm crossing over G.T.R.

16896—June 24——Naming express delivery and collection limits for city of Montreal, Que.

16897—June 26—Approving revised location of G.T.R. new track in town of Cobourg, Ont., lands of W. J. Crossen, and estate of J. G. Field.

16898—June 27—Authorizing C.P.R. to construct spur in town of Lasalle, Que., for N. K. Fairbank Co., Ltd.

16899—June 28—Authorizing South Ontario Pacific Ry. to open for carriage of traffic its line from Guelph Jct. and Hamilton, mileage 0 to 16.3.

16900—June 27—General Order re matter of indicating changes in freight, passenger and express tariffs.

16901—June 28—Authorizing G.T.R. to construct siding into premises of Congregation of Grey Nuns, Parish of St. Laurent, Que.

16902—June 27—Approving proposed change in siding track on Charles Street, in town of Berlin, County of Waterloo, Ontario.

16903—June 27—Authorizing G.T.R. to construct spur into premises of A. E. Rogerson, in Toronto, Ontario.

16904—June 26—Authorizing C.N.O. Ry. to construct across public road in Twp. of Ross, County of Renfrew, Ont.

16905—June 28—Approving location of C. N. Branch Lines Co. through Twp. [illegible], Range 4, west [illegible] M., Saskatchewan.

16906—June 28—Approving revised location of Kettle Valley Ry. Co. station 0-00 to 53-07.6, west of Penticton, B.C.

[illegible]—June 27—Approving clearances of Canada Malting Co.'s grain unloading shed at Winnipeg, Man., C.P.R., and G.N.R.

[illegible]—June 28—Authorizing V. V. & E. Ry. to construct highway crossing at Ashnola siding, B.C., for B.C. Government.

[illegible]—June [illegible]—Authorizing Esquimalt & Nanaimo Ry. to construct highway crossing between 2nd and 3rd streets in Duncan, B.C., at expense of city of Duncan, B.C.

[illegible]—June 28—Authorizing city of Hamilton to construct subway under G.T.R. at Birch Ave., near Sherman Inlet, Hamilton.

[illegible]—June 28—Authorizing Campbellford, Lake Ont., & Western Ry. (C.P.R.) to cross [illegible] highways between mileage [illegible] to [illegible] in Twp. of Hope, County of Durham, Ontario.

[illegible]—June 28—Approving location of Campbellford, Lake Ont. & Western Ry. from mileage [illegible] to mileage [illegible], and authorizing it to take railway lands of G.T.R.

[illegible]—June [illegible]—Authorizing C.P.R. (A. R. & I. Co.) to cross [illegible] highway, and approving location of branch line of railway from a point at mileage [illegible] A. R. & I. Co. to [illegible], known as Stirling Branch, Alberta.

[illegible]

[illegible]

[illegible]

[illegible]—June [illegible]—Authorizing C.P.R. to construct spur for Edwin Steele, [illegible] County of Prescott, Ontario.

[illegible]—June [illegible]—Authorizing C.P.R. to open for carriage of traffic its [illegible] at mileage [illegible], Saskatchewan.

[illegible]—June [illegible]—Authorizing C.P.R. to construct spur for Canada Lumber Co. [illegible], Ontario.

THE CONSTRUCTION OF DISTRIBUTION SYSTEMS FOR OUTLYING SYSTEMS AND SMALLER PLANTS.

By S. Bingham Hood.
Toronto Electric Light Company.

(Continued from last week.)

The best metal pin designed to pass through the arm is undoubtedly a design which has been placed on the market within the past year. This is of high carbon steel with bolt ½-inch in diameter. The shoulder is increased in diameter and drawn square, which not only stiffens the pin, but provides a wrench hold. The contact point with the arm is swaged out to form a good-sized shoulder, and the insulator thread is formed of a steel wire spiral which slips around in the insulator thread when expanding and contracting. This absolutely prevents insulator breakage and also that very annoying property of insulators to unscrew and become loose on the pin. These pins cost about three times that of a locust pin, but are an excellent investment, as, being hot galvanized, there is practically no limit to their life, and, while they may be bent, they will never break and drop the line. Another feature that makes them an economy is the small amount taken out of the arm for the pin hole. A wood pin leaves only 2 inches of wood out of a total of 3½ inches, while the steel pin leaves 3 inches, or 50 per cent. more, which not only adds to the strength of the arm, but also materially to its life. For heavier strains the same makers have recently brought out a clamp pin made of a bend of ¾-inch channel. A "U" bolt of flat steel is used to clamp this to the arm and insulator support is their usual steel spring thread. Such a method of fastening effectually does away with any possibility of the arm spliting and for heavy or important feeder lines makes an excellent job at very moderate increase in cost, the pin and clamp averaging complete about twenty cents.

For dead ending a line, particularly with large wire, the best pin made is an unsafe proposition and for such use some form of strain insulator with bolt right through the double arms should be used. The writer has not located up to date a device which can be purchased in the open market and which meets the requirements. We are using, however, a malleable iron clevis adapted to take a standard ⅝-inch bolt and using a porcelain spool insulator held in position by a ⅝-inch pin with cotters in each end (see Fig. 3). These can be made up cheaply in any shop and make a dead end that can't get away. We also use a ⅝-inch eye-nut where it is desired to head guy the arm, this placing no strain on the arms other than actually holding up the weight of the line.

The balance of pole hardware is now standardized, but, above all, should be hot galvanized only; plain iron for bolts or braces being both an expensive and dangerous proposition for use with treated poles, as they will not outlast the pole which should be the first part of the line to give out from age.

For taking off services and branch lines we are all familiar with the wooden side block and the reverse or buck arm. For junction poles at important corners the latter may be necessary, but for other places either is such an eye-sore that their use should be condemned in the strongest terms. For this purpose some form of metal spreader bracket should always be used. Various styles of malleable iron brackets have been on the market for years, but have defects which are too well known to need mention here. Fortunately it is now possible to obtain a full line of wrought steel brackets to meet every possible need. These are unbreakable, of light weight, and have a spring thread similar to the metal pins mentioned above. As the heaviest pattern of three-pin bracket costs only about one-half dollar, and a light two-pin about 20 cents, the cost is low enough to make their use general. For attaching to buildings the same line of brackets are available, together with a number of other styles adapted to building use only. With such fittings available there is no longer any excuse for unsightly and shipshod methods of taking off or attaching service leads.

A method of running secondary distributing mains which is finding favor within the past few years is that of dispensing with cross-arms altogether. The three wires of the system are carried in a vertical plane on brackets fastened directly to the pole (see Fig. 4). A three-pin metal bracket for this purpose will cost erected about 50 cents, which is less than the cost of a cross-arm. With this method of suspension the lines cannot swing together, and consequently, can be placed on very short spacing, decreasing the inductive drop on A. C. lines. A further advantage of this method is the ability to take off service lines directly from the line pins without crosses in the line. For dead ending these lines a three-spool insulator bracket is used, secured to the pole with two ⅝-inch through bolts, forming an anchorage which will stay as long as the pole holds up. As we have a number of 500,000 C. M. mains carried on this type of bracket some idea of their strength can be realized. Reference to the illustrations will demonstrate the vast gain in appearance which can be made with this type of construction in comparison to the old cross-arm method.

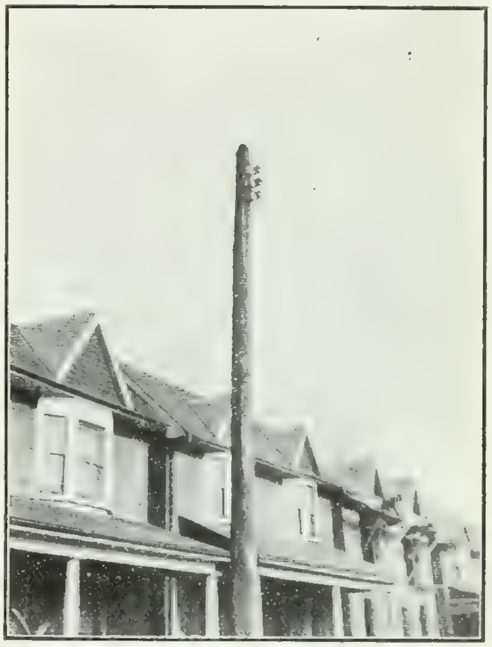

Fig. 4.—Vertical Secondary Distribution.

Before going into the question of wires a few words on the subject of joint poles may be opportune. Aside from the beneficial effect of minimizing the number of poles on the highway, as regards public opinion, the joint use of poles offers great economy both as to first cost and upkeep expenses. The telephone or telegraph is found practically every place where electric light or power is required, and there is no valid reason why both classes of public service companies can not beneficially co-operate to utilize each other's investment to the maximum. Where both systems are on the same street, as they must be to supply service, there is always the chance of the two systems becoming crossed owing to falling wires. This is equally true irrespective as to whether they are on separate pole lines or on a joint pole. For ordinary distribution under suburban conditions of load density a pole heavy enough to properly carry either system will just as safely carry both. This is due to the strength of a pole considered simply as a prop being far greater than the maximum load it must bear. With the wires and services of two systems on the same pole the bracing effect would be materially greater than where each system has its own pole line. With up-to-date construction where the lighting secondaries are carried in a vertical plane on brackets and the telephone is either lead cable carried on a messenger wire, or drop wire carried in rings for short branches, the appearance of the line can scarcely be considered as an objection beyond that which is an unavoidable evil made necessary by advance in our civilization.

From the financial standpoint we will assume for argument that the one company selects as a standard a 30-foot by 6-inch treated pole costing $10.56 in position and having an annual charge against it of $1.49. The other company must cross and re-cross the first line and finds these conditions require a 35-foot pole with 7-inch top, costing $14.47, and having fixed charge of $1.84 per year. The total expense to both companies is then $25.03 per pole, with a total annual charge of $3.33. The average charge would then be $12.52 and $1.66 respectively. Now, the joint pole line proposition, using the 35-foot by 7-inch pole, would only cost each company $7.24 capital expenditure and $0.92 annual charge, a clear saving to each of about 42 per cent. in investment and 44 per cent. fixed charge. In actual practice it is not necessary or desirable to have any real joint ownership. All that is required is a working agreement between the companies, giving the methods of construction necessary to make a uniform standard, and some provision as to notification when one company desires to utilize a pole belonging to the other. Having such an agreement compensation can be based on a yearly rental. By referring to Table 1 it will be at once evident that, under ordinary conditions of suburban distribution a rental of one dollar per year per pole would average about right and require little or no bookkeeping to keep the accounts straight. It is fair to suppose that, where true co-operation exists, as it should, one company would use the other company's poles about equally, so that any excess or deficit in the rentals would be wiped out by the law of averages. Indeed, were it not for the standing given any joint pole agreement due to a definite compensation being established, there would be no real reason for establishing any charge whatever between the respective companies.

Having selected the various fittings which combine to form a uniform method of construction the actual running of the wire is a simple matter. Any economy to be gained here is largely that due to the selection of a distribution system adapted to the requirements of the load to be served. As to the kind of wire to use, copper is the only choice. Aluminium wire may offer economies for transmission work, but for ordinary distribution it is unsuitable owing to the large span dip necessary to avoid overreaching the tensile strength of this metal. This extra dip would usually mean a higher pole, the cost of which would offset the saving in metal. In addition, aluminium, owing to its light weight, and greater sag for large conductivity, will swing and whip [illegible] in a wind to an extent that introduces all kinds of complications where space will not permit wide separation of the conductors.

The [illegible] [illegible] [illegible] [illegible] only A.C. systems. The frequency is based upon that of the generating [illegible], which generally [illegible] is planned. This is generally already fixed before local distribution is considered and may be anything from 25 to 60 cycle. For lighting 60 cycle has undoubtedly some advantages, but the idea that frequencies as low as 25 cycle are impractical for this purpose is entirely in error, provided your generators have a wave from approximating a smooth true sinu-soidal curve. Low wattage metallic filament lamps show a very bad flicker on frequencies below 30, but it is so easy to educate the public to the use of higher candle power units for the economical lighting of rooms, in preference to several small units, that this objection is not serious. In lighting large areas indoors, for amusement places principally, where large numbers of small units are used, the "25 cycle flicker" is very pronounced as soon as the illumination exceeds a certain critical point. In this case the flicker should be welcomed as a warning that the bounds of good illumination are being exceeded; the flicker being a sure sign, if noticeable, that the eye of the observer is under undue strain owing to excessive amount of light entering the retina; consequently it is unable to adjust itself to the variations in intensity between cycles. For arc lighting low frequencies are objectionable, but as the arc for interior illumination is now practically obsolete, having been replaced by tungsten clusters with greater all round reliability and efficiency, low frequencies do not introduce serious complications here either.

Taking all these points into consideration there is no reason for complicating the system by introducing frequency changers. If the frequency is not already selected, and rotary converters are not intended to be operated on the system to any great extent, then 60 cycle is probably the best standard to adopt. If the bulk of the output will be used for power purposes then a lower frequency may offer some advantages, and, for American practice, 25 cycle would be the standard. Unfortunately this particular frequency does offer some slight disadvantages from a lighting standpoint, as mentioned above. Experiments have shown, however, that just slightly above 25 cycle these defects disappear. With this in mind a running frequency of about 27½ is a marked improvement and can be obtained by simply running standard 25 cycle apparatus proportionately overspeed.

For the generating equipment there is no question but what multiphase current is necessary. This may be either two or three-phase with the latter far in the lead as regards efficiency of distribution. For this reason only the three-phase system will be considered. This system is commonly operated delta connected, but of late years the star connection is finding more and more favor where distribution networks cover large areas. In fact, the writer ventures a prediction that the next decade will see all our systems operated star connected with a solidly grounded neutral. If we stop to consider that, under operating conditions, our insulation strain is nearly always that between phase wire and ground, and not that between wires, it is at once clear that operating at only 58 per cent. of the voltage which our insulation is designed to stand is pretty poor economy. We can reconnect the same apparatus in star and operate the same line to transmit three times the power. In order to operate successfully in this manner it is imperative that the neutral points of the star be solidly grounded, not only at the ends, but at frequent intervals on the line. With this grounding there will always be more or less earth current which may cause interference with adjacent telephone or telegraph companies. To minimize this it is advisable to run a neutral conductor throughout the network, so that under only abnormal conditions will the earth be called upon to carry current. As ground lines have been demonstrated to be advantageous for lighting protection, and are quite generally in use on transmission systems, it is only necessary to substitute a wire capable of carrying the maximum neutral current in phase of the ground wire, the added expense being slight.

The question of grounding is one which has been under discussion for years past, but to-day is still being argued. The advisability of grounding below 250 volts is seldom questioned, the problem being simply that of getting a permanent ground. Here, however, the problem is supposed to be one of life hazard only, and the increased efficiency and reliability of a system when its position in relation to earth potential is definitely established appears to have been entirely overlooked. Any electric circuit, unless effectually grounded at some established potential point, is like a lost soul floating around in space. Its potential to earth may vary by thousands of volts, irrespective of its normal working voltage.

It has been a fixed law of the universe from the days of the creation that all things must start from the earth's surface, either up or down. The writer is firmly convinced that electric circuits are no exception to this law, and, unless we firmly anchor them to the earth, sooner or later something will happen with disastrous results. This subject is one which alone could be made to cover a paper as large as the Good Book we all try to follow, and, as the proof of the pudding is in the eating, those who have not tried grounding can get all the proof needed by adopting this method. By "grounding" we mean, however, SOLID GROUNDING, and not driven pipes, plates buried in coke, so-called grounding cones, limiting resistances and what not. A pipe forming a portion of a buried piping system is the only successful ground the writer has so far discovered. Our results following grounded operation lead us to believe that every electric circuit should be grounded, irrespective of the voltage at which it operates. In transmission circuits the objection to solid grounding has always been that a ground on any of the three-phase wires renders the system inoperative. This is undoubtedly true, but if the system has normally operated ungrounded, will not some unexpected weak point break down when subjected to full potential to ground? In this case, and it will be true in many cases, the system will fail to operate anyhow. It is very nice from an operating standpoint to hang on to our load to the limit. But, as engineers, it is good policy to continue in operation a system after it has developed what is known to be an abnormal and dangerous fault?

With the three-phase four-wire system, having solidly grounded neutral, there is one advantage which particularly applies to suburban distribution where the lighting load forms a large proportion of the whole. This is the ability to operate two of the phases after the third has developed a fault which renders it inoperative. The load of faulty phase can be transferred to one of the good ones and the lighting and single phase motor load carried until permanent repairs are made.

For suburban and semi-urban distribution it does not follow that because our generating system is three-phase the entire distribution must be the same. For lighting circuits the simplest and best secondary distribution is the single-phase three-wire system. In order to permit of inter-connection of these secondaries into a network covering a considerable area a single-phase primary is desirable. With this in mind it is now almost uniform practice to distribute lighting by single-phase sub-feeders, either balancing on different phases at the main bus or at selected points on a three-phase feeder line. For power distribution it used to be considered necessary to have multi-phase currents, but recent developments have overcome this for motors of small size, say up to 15 horse-power. For these the modern single-phase motor fulfils all requirements and greatly simplifies the distribution and metering problem. Motors on suburban lines seldom exceed five horse-power and up to this size they can usually be operated off the lighting network, unless frequent starting and stopping is necessary and their use extends regularly over into the lighting peak. In this case, and in motors of larger size, individual transformers are desirable. Where these are necessary they should have their neutral point connected to the lighting neutral, which, of course, is solidly grounded. If this point is overlooked we do not properly protect our power customers against high tension crosses or leakage.

As to the point where it pays to distribute three-phase from the sub-station or generating station in preference to single-phase, neglecting demands which may arise for large motors. This is where the investment for copper, in position, for the three-phase (four-wire) feeder equals that for a single-phase line. As No. 4 wire is the smallest which should be used for distribution and give the requisite margin of mechanical safety, it will be found that a No. 0 single-phase line is the largest that should be run. In fact, if No. 0 is requires then preference should be given to the four No. 4 wires operating three-phase grounded star.

Fig. 5.—Four-Wire Common Neutral System.

After having overreached the economical bounds of single-phase feeder distribution and having adopted three-phase, the question comes up as to at what limit the latter becomes uneconomical when operated at the utilization voltage, or the voltage at which the distribution transformers are operated. This limit has been increased three-fold by the adoption of the four-wire system, and it is now possible to transmit at the working voltage a considerable amount of power over a considerable distance. A No. 2/0 circuit will deliver about 300 kw. a distance of ten miles without exceeding economical limits of line loss under ordinary suburban load conditions and average initial power costs. This is sufficient to feed a pretty well developed suburban town.

A rough rule which has been used for some years is to allow 1,000 volts per mile. This is simply a rule of thumb, and is disproved right in the above case where this rule, if applied, would demand a transmission voltage of 10,000 in place of 4,000 as shown.

In the transmission of moderate amounts of power the craze for high voltage transmission lines can very easily get the best of one's common sense if we are not careful. The general rule in this regard is that the annual cost of energy lost in the line equals the annual cost for depreciation and interest on the line when maximum economy has been reached. In those cases where the selected voltage requires either step up or step down transformers, or both, the cost of these, together with their switching arrangements, must be included in the line investment. In many cases the cost of these, if put into additional copper, would carry the same amount of power with equal economy and cut out just that many links in the chain of trouble.

In designing any line the prospective future growth of the territory must be considered, and if this is promising and will eventually overreach the economical limits for 4,000 volts, then the line should be designed for high tension operation. In doing this it is as well to go the limit, which for this class of work is about 25,000 volts. The extra cost for wider spacing and larger insulators is so small that the extra investment is certainly warranted if future prospects look anywhere good. Such a line can be operated at 4,000 volts until such time as it becomes loaded. Step up or down transformers can then be installed and the change over made. There is no good reason for operating higher than reasonable requirements demand, and, consequently, the transformers should be purchased with double primary coils and operated at half voltage until the full pressure is required.

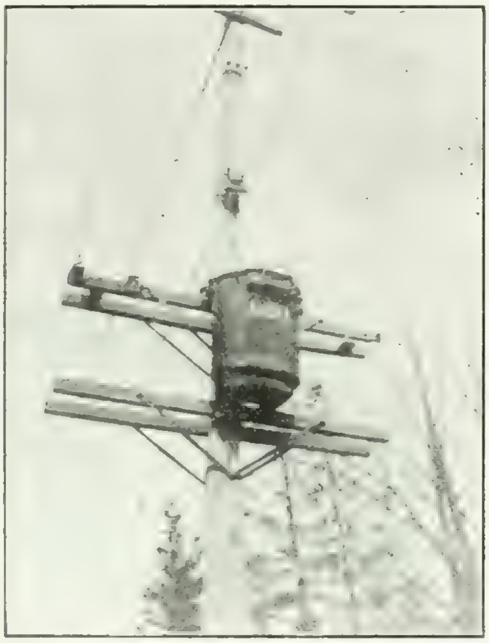

Fig. 6.—Single Primary Fuse Block.

For distribution over a large area from a central generating station the writer particularly favors a method which is only made possible with the adoption of a solid grounded neutral three-phase four-wire system. This is the use of auto-transformers in preference to the regular double coil type. It will be shown later on how these work out for general distribution, and their use in transmission will now be explained. With the grounded neutral system and using step down transmission, we would have in the complete system, under ordinary practice, no less than three neutrals; the secondary, the primary, and the transmission. Each one of these being solidly grounded is to all intent and purpose one wire as far as potential is concerned. The natural thing to do is to combine them mechanically as well as electrically. The neutral current distribution is somewhat [illegible] and while capacity must be provided to carry the greatest unbalanced load in practice the currents are very small. In using a common neutral for all systems a single wire of the same cross section as the larger of the three separate neutrals will fulfil all requirements. The current distribution in such common neutral is somewhat peculiar in that the [illegible] appears to be only that due to [illegible] and not that of the combined currents flowing. The [illegible] may be that due to the combining currents [illegible], as under certain conditions, the neutral current from one system will flow in the opposite direction to that in the other and consequently tend to neutralize it. This is one of the great economies made possible by a solidly grounded neutral.

As regards the auto-transformers, as used for transmission. Take a single coil transformer having its winding split up into four equal sections, each having a voltage of 2,300. As a regular transformer assume this to have a capacity of 100. Connecting these coils two in parallel and the two sets in series we get an auto-transformer of 1:1 ratio. One end of the coil goes to neutral, the middle to the distribution phase wire, and the other end to the transmission phase wire. Here we transmit approximately 8,000 volts on the delta and step down to 4,000 volts for distribution, the star voltages being respectively 4,600 and 2,300. The capacity of this auto would then be 200 and the investment for transformers but one-half that for the straight transformer connection as now used generally.

By connecting two of the sections in series and these in turn in series with the other two coils in parallel we get a ratio of 2:1 and transmit at approximately 12,000 volts delta with a capacity of 150, the transformer investment being but two-thirds that of the old method. A transformer of this kind would be insulated for 7,000 volts between coils and core and proportionately between coils; but at no time would but a small portion of the winding be operated under this pressure, which would drop uniformly, throughout the winding, from maximum to zero.

The same principle can be carried out up to the highest limits of transmission voltages, but, of course, the economy in transformer investment becomes less as the ratio between distribution voltage and transmission voltage becomes greater. In very high voltages a further saving in transformer costs may be effected in that the maximum insulation need be only that for the star voltage and this insulation can then be shaded down from this to a very small amount at the earthed star connection, only one high tension bushing being required, as it will never be necessary to reverse the windings in order to get the star voltage distribution to come right.

Another point of economy in the grounded neutral is that where a portion or all of the circuit is carried through lead covered cables. With a neutral not solidly grounded a four-core cable is necessary. With the solid ground it is not even necessary to pull in a bare conductor in the ducts as we already have a lead sheath capable of carrying, in a 3-core, 250,000 C. M. cable, about 100 amperes without heating enough to interfere with capacity of the cable. By bonding all sheaths together a combined capacity far in excess of any normal requirement is obtained.

In operating this grounded common return system the first requirement after erecting the pole line is, of course, the running of this common return wire. For all ordinary cases of local distribution a wire of the equivalent of No. 4 copper is ample in size. From an operating standpoint it should be insulated with regular weatherproof insulation and supported on glass insulators if wooden poles are used and high tension wires are on same poles. This is not to insulate the return wire, which electrically can just as well be bare, but to prevent linemen working on the poles and handling high potentials coming in contact with the grounded conductor. An insulated wire is also of some benefit if a high potential wire falls over it, that is provided the other wire is also insulated and potential to ground does not greatly exceed 2,300 volts. In other words, for potentials up to 4,000 volts delta use insulation on all lines, and above this point omit insulation on the high potential and do not depend on it as a protection against crosses between the high potentials and the adjacent low potential circuits. Insulation which is not a protection is a death trap, and its omission is both a safeguard and an economy. This common return main must, as already stated, be permanently and effectually grounded. This condition can only be obtained by attaching to an underground piping system at a number of points. Fortunately, but few towns of even small size are to-day without their local water supply systems, and even the farmers quite generally have their own piping systems leading from a well to the various buildings. This makes it comparatively easy to get good ground connections.

In introducing services good practice demands some form of sealed service box in order to prevent theft of current and prevent the consumer inserting service fuses dangerously large for his installation. This makes it imperative to enter the building through conduit, and the natural place to enter in this manner is the basement or ground floor. The fire underwriters require these conduits to be grounded to a piping system, and, by so doing, have made it very easy for us to get our common neutral grounded at every conduit service at a cost of but a few cents each. The process consists simply of placing a jumper between the conduit ground wire and the service wire which connects to our common return on the pole. This may be done at the service cutout and requires but a few inches of wire and a few moments of time. The various distribution neutrals should be cross connected as often as possible in order to form a series of neutral rings throughout the system. This makes it impossible to open the neutral or leave it unprotected by grounds, and, incidentally, permits of economic utilization of a cross section greatly in excess of that on any one street.

Transformers connected to this common return system are of the usual standard type, stepping down from 2,200 to 110/220 volts. The primary supply requires, however, but a single wire, which can advantageously be attached to an insulator on steel pin placed directly in top of pole. This type of pole construction, using a three-wire secondary main supported on steel vertical bracket, makes an unusually neat, as well as economical, design (Fig. 5). In making extensions the three-pin secondary bracket is installed throughout the run and the common neutral placed on centre pin. The outer wires of secondary are then extended both ways from the transformer as required, and, when they meet, are interconnected. This makes possible a secondary distribution interconnected throughout even in new districts, the rule to apply being to extend secondary beyond the primary or in preference to installing additional transformers up to the point where the annual charges for outer wires of secondary system would equal the fixed charges of an individual transformer, giving careful consideration to the point that copper wire has a well fixed scrap value on which to base depreciation, whereas a transformer may last two years and may last twenty.

In connecting the transformer for standard ratio of 10 and 20 to 1 but one primary lead is used, being protected by a single pole fuse block (Fig. 6). The other end of primary coil is connected inside the case to the neutral secondary lead. This connection may, of course, be made outside, but it is neater and better if made inside. This same transformer may be connected to either boost or crush 5 per cent. by simply tapping the other end of primary to one or the other outer leads of the secondary instead of the neutral. This gives, when connected to boost, an increased capacity of 5 per cent. The ratios thus possible to obtain without primary tappings are 19:1, 20:1 and 21:1. For transformers regularly supplied with 5 and 10 per cent. taps additional ratios of 17:1 and 18:1 may be obtained. This makes an ideal system for suburban distribution, as the transformers in various towns may be so connected that their ratios bear an approximate relation to their distance from the main generating station and fair peak load regulation should be possible without individual feeder regulators, bus regulation being used entirely. For first-class distribution, however, the automatic induction regulator for each feeder is the only solution. These are fairly expensive, but their cost is well warranted by the results obtained, particularly in the case of a feeder supplying several small towns or separate load centres. For a single feeder this condition requires very heavy wire between the load centres in order that the difference in primary pressure may be very low. This frequently makes it necessary, where local regulation is not used, to run separate feeders to each centre. With an automatic regulator installed at each load centre absolutely uniform pressure may be obtained in every town, even if several are supplied from same feeder. The local substation need be but a small building and requires very little attention, a visit once per week to clean and inspect the regulator contacts being all that is required. This plan of supplying each load centre from a small substation is of further advantage in that automatic protective devices may be conveniently installed here to cut off this particular section in case of trouble. The regulator is supplied by its own potential and current transformers, and a single phase 5 ampere integrating secondary wattmeter may be installed on the same transformers, thereby measuring at very small expense all the current delivered to this particular section. This is of particular benefit to both the distribution and commercial departments, as it enables them to check up the line losses and also the revenue obtained from any one load centre or district.

In selecting the size of pole transformers and the type of secondary distribution, local conditions must be studied carefully. Unless the load is very badly scattered, relatively large transformer units feeding a large interconnected secondary network makes the most economical as well as most reliable system. Transformers may be confined to three sizes, 5, 10, and 15 kw., the latter used for large concentrated loads and for feeding the networks. The small size will be found useful in feeding isolated loads and to help out the tail ends of a network while the business is growing, being changed when load conditions warrant for the larger size. The intermediate size will be found useful in networks of moderate size, as not less than three transformers should ever be interconnected, and small villages will frequently not warrant the installation of three 15 kw's.

The outer secondary leads of all transformers should be protected with low tension fuses, the neutrals, of course, being connected solid. In networks a fuse may also be inserted in the mains half way between transformers; in fact, this is necessary unless the primary feeding the network can be disconnected in case of trouble. Unless this is done the transformers banked can not be re-fused if they blow out under load. In large networks the better practice is to connect solid and depend on the heavy current available to burn off faults, etc. Just a word of caution, however, in regard to these secondary fuses. They are exposed to the weather and an ordinary lead and copper tip fuse will disintegrate. Use cast brass or copper contact posts and wing nuts and copper fuses. A plain copper wire supported on about four-inch centres makes an ideal fuse for exposure to the weather. No. 18 B. & S. gauge will carry about 100 amperes, No. 16 150 amperes, and No. 14 about 200. An ideal distribution is shown by Fig. 2.

In high-class suburban districts occasional demands arise for underground distribution. This can be cheaply and reliably handled by simply laying the cables solid in the earth, covering them if desired with a treated plank to prevent mechanical damage. The common neutral may be a bare copper wire or plain weatherproof insulation. This type of construction for secondary distribution does not greatly exceed the cost of a first-class overhead line when upkeep and replacement costs are considered, and, being laid usually under unpaved streets or grass plots, can be opened up for repairs or extensions at minimum cost. Service taps are taken off through a small cast metal box enclosing the joint and afterwards filled with compound. The actual tap is usually made through a single strand of copper wire which will fuse under short circuit conditions and disconnect the defective service. If single branches are made the box should be of non-magnetic metal, to avoid inductive effects. If made of cast iron the box must enclose all wires of the main, and these must enter through a non-magnetic bushing. Lead makes the best metal for this purpose. On extensive underground networks junction points should be sectionalized in a pillar box placed near the curb at intersections. These would have somewhat the appearance of the ordinary stone carriage steps which used to be so common and do not constitute an eyesore to the general public.

It must be self-evident that a system on the foregoing lines can be installed with less upkeep cost than former methods, and, having fewer parts to cause trouble, must perforce be more reliable. As to just what savings are possible can only be determined by figuring actual cases; this saving is, however, very considerable, as has been proven by actual operation of such a system.

CANTILEVER FORMS FOR CONCRETE RETAINING WALLS*.

By Thomas J. Kelly.†

The accompanying sketch shows the cantilever system of concrete forming that is being used on lock walls at Mayos Bar, Coosa River, Ga. The first section is a stationary form, which is braced from the ground, the concrete being put in in lifts of 6 ft. each. In the second and succeeding lifts, bolts ¾ in. x 30 in., with nuts on each end, are put in the concrete 10 in. above the bottom and 10 in. below the top of the lift, and 4 ft. apart, leaving enough of the bolts outside of the concrete to go through the lagging, uprights and wales.

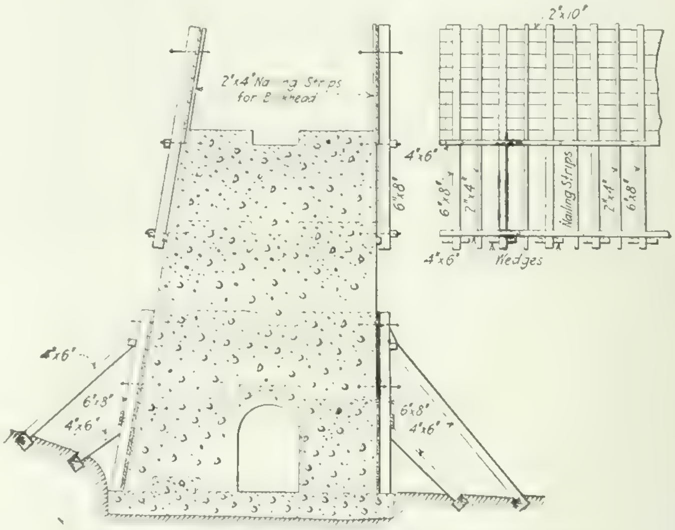
When the concrete has sufficiently set, the lower form is removed and holes bored in the walls to correspond with each bolt. The wales are then put on the bolts and uprights are put in between the wales and concrete, first putting one piece of lagging on top of the upper bolts, next to the face of the concrete; wedges are then driven near bottom end of the uprights, between the face of the concrete and the uprights, these wedges being used to line the forms and keep them rigidly in place.

The bolts should be left outside the forming, as shown in the upper left-hand of the cut, until just before the concrete reaches this point; they should then be greased with [illegible] and [illegible] to the proper position.

Sometime during the next day the bolts should be given a few turns with a wrench, so they will be loose in the concrete and can be removed at any time, and the holes plugged with neat cement. Nailing strips, 2 x 4 in., are used to tack the lagging together, and a strip of the same size is also used to secure the bulkhead or end forming, in place.

After the form has been used for the first time, the [illegible] can be taken up bodily with the derrick, and lifted to the next position, being allowed to rest on the top bolts [illegible] the wales are being bolted on [illegible] the upper row of bolts can be removed and used repeatedly, with only the loss of one nut each time, which loss is inexpensive.

In the writer's opinion, this is the most economical system of forming in use to-day, both as to cost of material and cost of erection, for the lumber and other material can be used over and over repeatedly.



Details of Cantilever Forms for Concrete Walls.

This system can be used to advantage on all classes of heavy masonry, such as lock and dam work, bridge piers and retaining walls; especially so where cyclopean masonry is used, as there are no rods or braces to obstruct the laying of large stones or in handling concrete buckets, and these forms can be used at a height of 100 ft., or more, as easily as at a height of 20 ft.

TESTS OF TILE AND CONCRETE WALL-SECTIONS.

The National Fireproofing Co. has recently had made for it a series of tests on sections of tile wall, varying from 4 to 10 in. thick and from 8 to 37 in. long, all about 12 ft. high. The tests were made by a well-known firm of engineers. In each test the crushing load, and the lateral deflection and vertical compression under various loads were recorded. Wall sections of concrete, reinforced concrete, and brick, and interlocking tile, were included in the series, with the walls of plain tile laid both horizontal and vertical.

The results of the tests are summarized in the table below. In arranging this table we have computed the failure load in pounds per square inch of gross cross-section of wall, this being the quantity usually taken into consideration in designing.

TESTS OF TILE, BRICK AND CONCRETE WALL-SECTIONS

Tests of Walls About 12 Ft. High					Comparison Tests of Single Tile	
Material	Age days	Horizontal dimensions, inches	Failure load lb. per sq. in. of gross cross-section		Bottom area, and position	Failure load, lb. per sq. in. gross sec.
Brick wall	47	8 x 43½	248			
Concrete wall	40	8 x 30	1610			
Reinforced concrete walls	55	8 x 30	2000 1st loading 1020 2d loading	no signs of failure		
Interlocking tile wall, side	13	8½x37	288		8x12, side	600
Monarch tile pier (laid up of 4x8x8 tile on end)	25	8½x 8½	2685		4x8, end	8350
Monarch 4" wall	25	4 x 43½	2500*			
Monarch 8" wall	47	8½x47	1200		8x12, end, av. of three	2700
Monarch 8" wall	45	8½x47	1140			
Monarch 8" wall	20	8½x40½	1080			
Natco 8" wall	28	7¾x45	570		8x12 end, av. of two	3050
Natco 8" wall	44	8 x40½	1220			
Natco 8" wall, side	28	7¾x40½	280		8x12 side	350
Natco 10" wall, side	44	9¾x40½	415		10x12, side	395

*Buckled

Tests of single tile were made, one for each tile wall section. We give the results for comparison with the strengths developed by the walls. The great variations of ratio between wall strength and tile strength are to be noted.

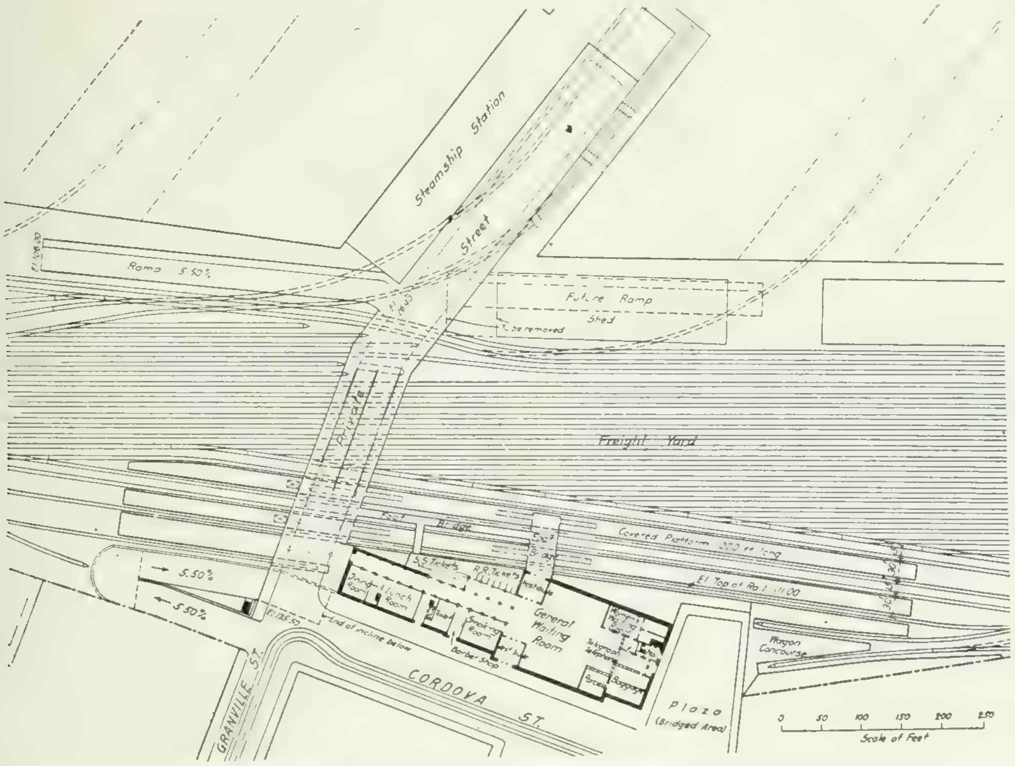
PASSENGER TERMINAL AND OFFICE FACILITIES, CANADIAN PACIFIC RAILWAY, VANCOUVER, B.C.

Plans have been prepared and work is now under way on certain improvements in connection with the Canadian Pacific Railway Company's passenger terminal at Vancouver, B. C.

The present passenger station of the Canadian Pacific Railway at Vancouver is located at the foot of Granville Street, near the shore line of Burrard Inlet. The station was built about fourteen years ago, and except for minor alterations, is unchanged from its original plans. The general waiting room and ticket offices are at the street level, and the baggage room on the track level which is about thirty feet below the street.

Along the water-front across the local freight yard tracks are located the steamship wharves. There are two large sheds on a jetty pier of recent construction used by the Trans-Pacific Steamship Lines; also five sheds adjoining the longitudinal wharves used by the Seattle, Victoria Alaska and other steamship lines of the Canadian Pacific Railway.



Plan of the passenger Station of Canadian Pacific Railway at Vancouver, B.C.

Between the wharf sheds and the passenger tracks adjoining the passenger station certain of the freight tracks serve the several sheds, and other tracks are used for drilling and storage. The yard tracks extend along the harbor front about one and a half miles.

By reason of its favorable location and the transportation facilities afforded by the enterprise of the Canadian Pacific Railway, Vancouver has grown from a trading camp to a well established city with over 125,000 inhabitants in about twenty-five years time. All business lines are represented in the commercial field centering at the city. Situated at the terminal of the first, and still the only, Canadian Transcontinental railway line on a fine natural harbor and with other favorable surroundings, its growth has been based on advantages which insure continued growth and permanency and there is every indication that its population will be not less than 300,000 at the end of the next decade.

The past growth has rendered inadequate the present facilities for handling the terminal business of the railway company and the general plan shown herewith has been adopted to relieve the present congestion, as well as to provide for reasonable growth in the near future.

The general scheme embraces a passenger station and office building suitably located on available land immediately east of the present passenger station. There will be four passenger tracks with provision for more when required, separated by wide platforms, between the station and the present freight yard. The passenger tracks are to be raised about five feet above the present track level to reduce the difference in level between the street and the tracks to about twenty-five feet.

In order to avoid an inconvenient grade crossing and delays to traffic between the city and steamship wharf a bridge on the line of Granville Street extended, is to pass over the passenger and freight tracks to the steamship pier and connect directly with passenger accommodations on the pier. An incline is also to be built leading from the west side of this bridge to the wharf giving access to the lower deck of the pier and freight sheds and the water-front.

Another viaduct over the tracks is to be built on the line of Burrard Street extended northerly with an incline giving access to the present Trans-Pacific pier and other portions of the water-front.

The main entrance of the passenger station will be on Cordova Street with the main waiting room located centrally in the station on the street level. Ticket offices serving the several classes of railway and steamship passengers are located at one end of the waiting room, and the baggage checking room, lunch and dining room, parcel room, women's waiting room, men's smoking room, news booth, information booth and other facilities are all placed immediately adjoining the main waiting room.

On the lower floors of the station are located the baggage rooms, express company's space, immigrant rooms, supply rooms, and other station facilities not directly used by passengers. Stairways and lifts connect the two levels of the station and also afford communication with the office floors above. A separate foot bridge is carried over the passenger tracks directly connected with the waiting room at one end and with stairways leading to the track level, giving access to platforms without crossing tracks at grade.

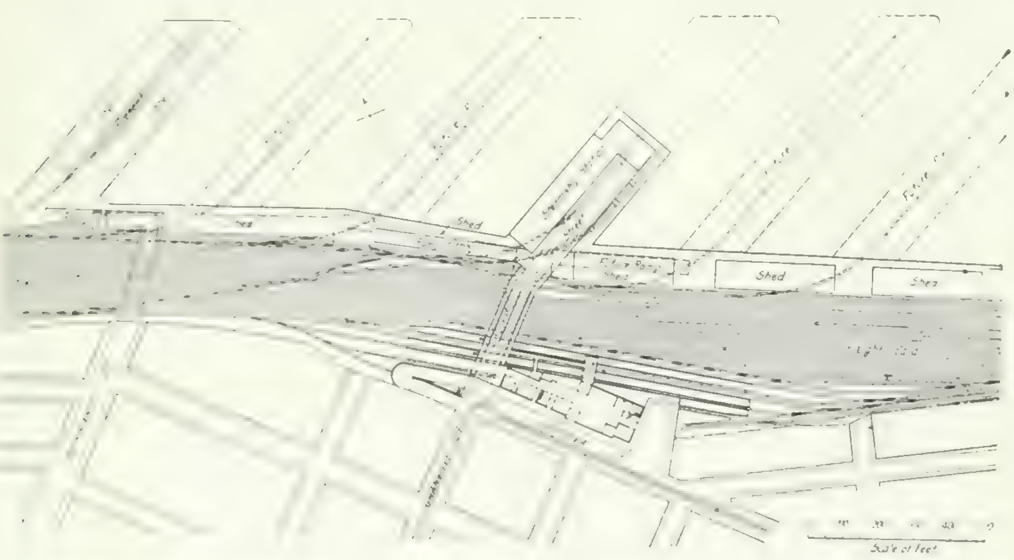
The track platforms are 1,000 feet in length, and are to be covered with shelter sheds of the umbrella type. The platform adjoining the station will be used only for baggage express and supplies.

Above the public rooms of the station building the space will be devoted to the general offices of the railway company. The interor arrangement of the office space will be adapted for a unit system of sub-division; that is, eac panel will have heating and lighting facilities so that partitions may be placed or removed at will in order to provide for changes in arrangement of office accommodations which may be desired from time to time.

The proposed steamship station on the pier is a two level building, the upper floor being devoted to the passenger business and offices and the lower floor to freight, baggage and express. There will be double level gangways on the west side of the pier, which will be used for the Victoria and Seattle service, the lower gangway being used for freight and the upper for pasengers; these gangways to be supported on floating pontoons to maintain the landing at constant level with respect to the boats.

On the passenger or upper level of the pier are provided waiting rooms, ticket offices, baggage checking room, customs office and other conveniences. Separate rooms are provided for outgoing and incoming passengers. Two tracks will be placed on the surface of the pier within the shed, and one track on the outside of the building for the direct handling of freight between cars and steamers.

The essence of the general design has been to secure easy lines of communication between the railway trains, steamers and the city. The traffic conditions at Vancouver are unusual as compared with other large terminals on account of the absence of suburban business. The aggregate number of trains is not large but they are long and frequently are run in several sections and contain a number of sleepers in trains.



General Plan Showing Layout of New Canadian Pacific. Passenger Station, freight Yards and Piers at Vancouver, B.C.

The designs for the terminal have been prepared by Messrs. Westinghouse, Church, Kerr and Company, Montreal, Calgary and Vancouver, in co-operation with the officials of the Canadian Pacific Railway and the construction of the station and facilities is now being carried out by the same engineers.

The capacity of contact beds diminishes in proportion to the length of time the beds are in service. In a paper before the British Institution of Municipal and County Engineers, Mr. T. C. Cook gives some figures regarding the [illegible] of capacity of contact beds at the sewage disposal works at [illegible]. In [illegible], five years after they had been placed in service, the secondary beds had a capacity of [illegible] per cent. of their original capacity; in [illegible], [illegible] per cent.; [illegible] per cent.; in [illegible] [illegible] per cent., and in [illegible] [illegible] years.

THE BUYING OF COAL.

Manufacturers and others who use coal in considerable quantity will be interested in Bulletin 41, of the United States Bureau of Mines, on the subject, Government Coal Purchases under Specifications. This bulletin, which has just come from the public printer, was prepared by George S. Pope, engineer in charge of fuel inspection for the government, and contains chapter on the fuel inspection laboratory of the bureau by Joseph D. Davis, chemist in charge. The bulletin is the fourth of a series showing the results of the purchase of coal by the government.

Mr. Pope, in his introductory says: "The purchase of coal on the dealer's statement as to quality, or on the reputation of the mine or district producing the coal is gradually being discontinued. At present most coal-purchasing contracts make definite provision regarding the desired heating value of a coal and the composition as shown by analysis. The heating value is usually expressed in British thermal units and the composition specified is that shown by proximate analysis. The price to be paid for delivered coal is made to depend on whether the analyses and heating-value of samples representing the delivery shows the quality to be above or below the quality set forth in the contract.

"Large coal consumers are beginning to appreciate more and more the importance of the cost of power as a factor in the cost of producing a finished article. The endeavor to increase the efficiency and the economical operation of a power plant calls for an intimate knowledge of the quality of the coal being used. The purchase of coal under specifications insures the purchaser getting what he pays for and the coal being of the quality guaranteed. In addition, the analyses and tests of the delivered coal furnish data whereby the power-plant results can be comprehensively studied and a continuous check maintained on the conditions of operation.

"The replies to a circular letter sent to the mayor of every city of over 100,000 population in the United States brought out the fact that about 55 per cent. of the cities replying purchase coal under specifications, many of which are similar to those used by the government. A great many industrial concerns are likewise purchasing coal under specifications. The numerous requests received by the Bureau of Mines for authentic information concerning purchase of coal under specifications, or according to its heating value, attest the growing interest in the subject.

"The purchase of coal on a specification basis is an important step toward the conservation of the mineral resources of the nation, for it results in the increased use of the lower grades of coal. The poorer grades find a market by competing with the better grades, not as to the price per ton, but as to the cost of an equal number of heat units.

"The purpose of this paper is to explain in general terms the method that the government has found most satisfactory for the purchase of a large part of its coal supply, including the consideration of bids, the awarding contracts, and the analyzing of samples on which the price corrections are based.

"In this report, for the information of prospective bidders or government contracts, a list of the coal contracts in force during the fiscal year ended June 30, 1911, is furnished. General averages of the analyses during the fiscal year 1908 to 1910, inclusive, are tabulated for the various sizes of anthracite and also for the several kinds of bituminous coal purchased for government use, and the results for the fiscal year ended June 30, 1910, are shown in detail by months. It is hoped that this information will be of value to both coal dealers and coal consumers."

Copies of this bulletin may be obtained by addressing the Director of the Bureau of Mines, Washington, D.C.

PRECISE LEVELLING IN CANADA.

By F. R. Reid, D.L.S.

(Continued from last week.)

Another source of error would be a systematic rising or settling of the rod supports, this would have a similar effect to the movement of the level, and cannot be guarded against in the same way, so it is essential that rod supports should be as solid and immovable as possible; luckily, in running along a railway the most solid supports are also the most convenient, namely the top of the rails. The rodman holds the rod with its semicircular knob on a cross made on top of the rail about one foot from the joint; this has been found by all levellers, I think, to be more satisfactory for a turning point than anything else; upon a track in ordinary condition the passage of a train appears to have no effect, the rail may rise and fall an inch or more under the passage of the wheels, but careful comparison of the elevation of the point with some solid point to one side, before and after a train has passed, shows that the rail returns to precisely the same elevaton. Of course when the track has been freshly ballasted and is consequently likely to settle under a train, a turning point is taken to one side when a train is known to be approaching. When following a highway, as when running branch lines into a town, suitable steel pins, driven solidly into the ground, are used. The verticality of the rod whilst readings are in progress, is maintained by means of a small spirit level. With regard to rod supports I will quote from the 1907 report of Mr. J. F. Hayford, Inspector of Geodetic Work of the United States Coast and Geodetic Survey. He says:—"In August, 1903, the experiment was made of using a point marked on the top of the rail of the railroad track as the rod support. The most prominent effect was to change the rate of accumulation of discrepancy between the forward and backward lines. This is a clear confirmation of the theory that the accumulated discrepancy is due mainly to a systematic rising or settling of the rod supports. This theory is based upon the frequently observed fact that when a change is made in the method of rod support or in the habits of the rodman, a change is liable to take place in the rate of accumulation of discrepancy between the forward and backward lines.

"The evidence showed clearly that the use of the rail for the rod support increased both the speed and accuracy of the levelling, and the practice has been adopted in all Coast & Geodetic Survey levelling since that time.

"Two uncertainties in connection with the method of rod support will occur to anyone who considers it carefully, namely, the uncertainty as to whether the rodman holds the foot of the rod for both foresight and backsight on precisely the same spot on the slightly rounding and sometimes inclined surface of the top of the rail, and the uncertainty as to the recovery by the rail of its former elevation after a train has passed over it.

"The first of these uncertainties is very small provided the rodman is careful. No difficulty was found in marking the exact spot on the rail which was used in such a way, with chalk or steel, so that the mark was recoverable, even after a train had passed over it.

"Direct observations have indicated that, as a rule, the rail rises to sensibly its former elevation quickly after a train passes. Doubtless there are exceptional cases. The best proof available that such cases are comparatively rare for the conditions under which the rail was used as a rod support, and that the systematic permanent settling of the rail caused by the passage of a train is exceedingly small, is furnished by the comparison given in Appendix 6—Report for 1904—of the accuracy of the levelling by each party before and after beginning the use of the rail as a rod support, and this has been confirmed by the good results obtained on later lines."

When a reading is to be made upon a permanent bench mark a chisel about one foot long and 1 inch wide, levelled to a flat edge at one end, is inserted in the cross mark in the end of the copper bolt, with the sharp edge at the top, that is, the upper surface of the chisel and the cross mark lie in the same horizontal plane; one man holds the chisel steady and maintains its horizontality by means of a hand level while the rodman rests the rod upon the top of it the same as he would upon the rail.

Foresights and backsights of approximately equal length are used, so as to counteract the effects of refraction and curvature, and of a possible lack of adjustment of the level; this equality is secured by having the rodman count the number of rails from the last turning point to the instrument and from the instrument to the next turning point, the instructions are that backsights and foresights should differ by not more than 30 feet.

At this point it will be necessary to say something about the programme of observation followed in the field. The observer sets up the instrument, levels it—as nearly as may be—by means of the three levelling screws, then points it on one or other of the rods and moves the object glass slid in or out till prefect definition of the rod is obtained, he then turns the drum of the micrometer screw, which is under the eye end of the telescope to the left or right, as may be necessary, to bring the bubble exactly to the centre of its run, watching it carefully all the while with his left eye. He then makes the three rod readings corresponding to the three cross wires as rapidly as possible, consistent with accuracy, still being careful to see that the bubble maintains its exact centre position; these readings are recorded by the recorder and the thread interval between the first and second and between the second and third obtained by subtraction; if these do not correspond within a certain limit—fixed for the particular instrument at the beginning or the season by careful observation under the best conditions— the readings are repeated until they do correspond; the mean of the three readings is used to ascertain the differences of level; the use of three readings usually shows up any mistake in reading feet or tenths which might be made in a single reading. The thread intervals obtained as above evidently will correspond to the length of sight, or in other words, the stadia method of obtaining distances is used; in a column headed "Sum of Intervals" these thread intervals are summed continuously from a bench mark, on the left hand page for the backsights and on the right hand for the foresights, this furnishes a ready means of equalizing the sights, if from any cause, they should become uneven, by setting the level behind or ahead— as the case may be—of the centre point between the rods; thus at the end of a section the total backsights and foresights may be made as nearly equal as desired.

When running up steep grades, the point read on the forward rod is much nearer the ground than that on the rear rod, consequently the effect of refraction, or boiling of the atmosphere, is to distort the foresight more than the backsight; by taking very short sights and thus keeping the line of sight away from the ground as much as possible, the effect is minimized but not by any means eliminated. The only way of doing the latter would be to wait for cool cloudy weather when there is no perceptible refraction. If one makes the forward levelling in such weather and the backward in a bright hot sun or vice versa the discrepancy is usually very noticeable; if both measures were made under the unfavorable conditions the results would show a good accordance, but both would be in error; however, the error would be compensated for on the next down grade provided the conditions were the same, so in the aggregate effect upon a line, I think this class of errors should not be classed as cumulative, the more so as in observing during a large number of days one will probably encounter good weather and bad weather combinations indiscriminately upon forward and backward running and upon up and down grades. My own experience has been that the grades have little effect as to causing the total discrepancy to accumulate. Atmospheric refraction affects the readings on the levelling rods most noticeably in two ways:—Firstly, when the ground is being rapidly heated by the rays of the rising sun, the lowest stratum of air becomes in its turn heated by the ground and begins to flow upward; this has the effect of making the readings appear to rise and fall vertically, and even to remain for a minute or so in quite abnormal positions; such conditions are unsuitable for observations. Secondly, when the air is bubbling the graduations on the rods appear to dance or vibrate; they are then difficult to subdivide, but no systematic error is to be feared.

The length of sight taken depends upon the atmospheric conditions; under the influence of a bright sun, without any breeze, especially when following a cold night, the boiling of the atmosphere is so severe that the divisions on the rod often cannot be subdivided with the proper degree of accuracy at a greater distance than 200 feet. Under average conditions, sights vary from 300 to 360 feet; on a very favorable day these may be lengthened to 500 or 550 feet or even more; with one of our instruments having a particularly good object glass, sights of over 700 feet have been obtained. The observer is left to use his judgment as to the length of sight he shall use; if he attempts to read farther than he should, the thread intervals will become irregular and time will be lost in taking readings over; in any case the gain in speed in taking sights of over 450 feet or thereabouts is not very marked owing to the time lost in waiting for the [illegible] to catch up.

The above remarks apply, naturally, to a level or almost level [illegible] grade, sights of [illegible] feet could not safely be exceeded in the best of weather.

Owing to these varying conditions it is very hard to [illegible] an average full day's work; probably [illegible] between [illegible] and [illegible] miles, [illegible]. In the course of a month, a few days and parts of days are lost from bad weather and [illegible] and relevelling and other causes of delay [illegible] about [illegible] per cent. of completed [illegible]

[illegible] full working days, [illegible] miles levelled per day [illegible]

line (levelled both forward and backward) is considered good progress.* These are supposed to be average conditions and are greatly exceeded sometimes under exceptionally good conditions, as over 12 miles have been done in a single day, and in one month, 87 miles of levelling were completed.

The amount of relevelling required should not amount to more than 10 or 15 per cent. provided weather conditions are at all favorable.

This class of work is so dependent for speed and precision upon the weather that it is found necessary to discontinue it in the autumn when the weather gets cold and wind storms become prevalent; the usual season for work is from some time in April till the end of October or the early part of November.

When carrying the line of levels along the railways the elevation of the top of the rail is taken opposite each station house and at the diamond crossings of all intersecting railways; these are tabulated in the office in a separate form of record from the bench marks and are useful as giving permanent records of the work in addition to those furnished by the bench marks; they are also very useful to the companies as they furnish a means of comparing their profiles with our levels without the necessity of making any actual connections on the ground as is usually necessary in the case of bench marks.

The elevations furnished in this way are not in any degree precise, and are only calculated to the nearest tenth of a foot, but they furnish a very practical record, nevertheless, and are in demand by engineers and others.

Adjustment of Instruments.—The collimation adjustment of the precise level is made in a manner very similar to that employed for the Dumpy level. Two solid points suitable for turning points are selected at, say, 360 feet apart and the level set up and carefully levelled at a point half way between them. The readings on the rods are made, and by subtracting them the true difference in elevation is known, regardless of whether the instrument is in adjustment or not. It is then set up with the ocular directly over one of the points on which the rod was held and the distance from the point to the centre of the aperture of the ocular is measured with a steel tape. By adding to or subtracting from this the difference of elevation of the two points, the result will be the true reading upon the rod held on the other point. Upon making this reading, should it not be within 0.01 foot of the true reading, the micrometer drum is to be turned till the centre wire intersects the proper point upon the rod as indicated by the true reading, then, by turning the adjusting nut at one end of the level vial the bubble is brought again to the centre of its run and this adjustment is complete.

The line of collimation is made to revolve in a plane at right angles to the vertical axis of the instrument as follows: the bubble is brought to the centre of its run, the telescope is turned 180 degrees in azimuth, half the error—if any—is corrected by the micrometer screw and half by the foot screws. For convenience the telescope may be placed so that the ocular is over one of the foot screws. The position of the zero of the micrometer drum after this adjustment is made—should be noted and used when setting up the instrument at a station; the drum may be placed at this reading before using the foot screws for "levelling up." In this way the adjustment of the level will be kept constant.

So well do the precise levels hold their adjustments that it is not often necessary to adjust them more than once in several weeks, though the adjustment is tried at intervals to see that it is all right. As the backsights and foresights are kept of equal length and no intermediate sights are ever taken, it is not a very serious matter if the level should be slightly out of adjustment in collimation. However, it is well to have it in adjustment if only for convenience.

Adjustments of Nets of Levelling.—When circuits of levelling are closed and when connecting links are run, it is obvious that new elevations will be obtained for bench marks at junction points, unless all work were performed with absolute accuracy, a condition which is, of course, never attained in practice. The question then arises "How much change will be necessitated in the published elevations of bench marks on the original lines of levelling?" I will again quote from the 1907 report of Mr. J. F. Hayford. He says:—"It is a great convenience to have fixed assigned elevations for bench marks—standard elevations, so to speak—to which all other elevations in surrounding regions shall be referred and to make no changes in these values unless necessary. Every change in the assigned elevations of the principal bench marks is liable to cause inconvenience to engineers outside the survey, as well as to the survey, by making extensive changes necessary in computations based upon these assigned elevations. On the other hand, however desirable it may be to have fixed values for the elevations of the principal bench marks, and so to make no changes in those which have already been given to the public in print, it is not desirable to keep a value for an elevation unchanged, when later levelling gives a value differing from it greatly which is determined with a higher degree of accuracy. Therefore, it is never possible to adopt a final standard value for the elevation of any bench mark unless it is positively known that no more precise levelling connected with the net will be done, or else that, if done, it will not be utilized to improve the existing assigned elevation, for all new levelling, besides giving elevations for points not previously determined, affects, by its connections, many elevations in the net as already adjusted, the effect being necessarily greater in the vicinity of the new levelling than in regions more remote. But if all new levelling is to be utilized to the fullest extent in securing elevations of the highest degree of accuracy in every part of the net, then whenever new levelling forming links in the net is secured, the whole net must be readjusted and the old adjusted elevation must be completely superseded by the new.

"Neither of the radical plans indicated above—either to hold all old elevations without change and merely to fit new levelling to the old, or to supersede all old elevations by new ones seems desirable. But a conservative procedure, intermediate between the two is possible.

"If after a complete re-adjustment of the level net the change in the published elevation of any junction point required by the new adjustment is very small, or in other words, elevations from the old and new adjustments agree closely, it seems best to hold the elevations already published. Especially does it seem certain that whenever the change called for by the new adjustment is much smaller than the uncertainties in the new adjusted elevations, no change would be made. So, also, when for any link in the net the new adjustment gives a difference of elevation far within the limits of uncertainty of the new adjusted difference, it seems that th old difference of elevation should be held without change, even though a constant correction to the elevations along the line is found to be necessary."

In India, where a system of levelling has been carried on since 1858, a complete report has lately been published by the Great Triangulation Survey in which a thorough adjustment of all precise levelling up to 1900 is made, by the method of least squares; before this publication, arbitrary methods of adjustments were adopted, in most cases by giving infinite weight to the older lines and then fitting the new levelling into the old. Such discrepancies arose, however, that a complete readjustment, by a scientific method was found to be necessary. I will quote from this volume as follows:—

"It is necessary to point out that in the future we shall have to relapse again into arbitrary methods that we are denouncing and abandoning. In this volume the circuit errors will be adjusted and the heights of all bench marks erected between 1858 and 1900 will be fixed. Any level lines subsequently observed will have to be fitted to the adjusted level net. The lines forming the level net will thus be accorded a greater weight than those observed subsequently to the reduction of the level net; from a scientific point of view this is not quite satisfactory, seeing that the future lines of levelling which should be more accurate than the old, will be subordinated. But we are in the same dilemma as our predecessors and we cannot postpone publication of results, or wait for a finality which is unattainable. Topographers and engineers, who make use of our bench marks, only ask us to eliminate contradictions and to provide them with accordant values of height, such as they can regard as final; they deprecate frequent modifications and disturbances of values.

"This volume will therefore furnish values of heights sufficiently reliable to serve all purposes for at least half a century. In 1958 it will be open to our successors to reconsider the question and to readjust the level net of India. By that time there should be a second level net superimposed on the first; the second will consist of all lines observed between 1908 and 1958, and will be attached to new open coast tidal stations which have not as yet been connected with the levelling net work. The second level net (1908-1958), will be a more scientific work than the present one (1858-1908). It will then be interesting to see what differences in value will occur in the heights of those bench marks that are common to both nets."

In the adjustment of this Indian level net the weights assigned to the different lines were made proportional to the reciprocals of the length of the lines. There were 86 lines of levels forming 29 circuits, which were tied to mean sea level at 9 points; these 9 tidal points were given infinite weight in the adjustment, and the elevations of all the junction points in the net were computed by the method of least squares. The correct elevation of the junction points and of the terminals of lines being given, the corrections to the observed heights of intermediate bench marks on the main lines were interpolated betwen the terminal points. In the interpolation on any particular line the corrections were assumed to vary at a uniform rate along the line. For any branch line that terminated without a second connection with a main line or with sea level, a constant correction was applied throughout, equal to the correction applied to the height of its junction point with the main line.

The problem of making adjustments has not come up as yet with us in Canada, for, as was mentioned earlier in this paper, only two circuits of our own levelling have been closed—in Western Ontario—and they were only completed at the end of last season. It is satisfactory to note that there are no large errors of closure to be disposed of there.

Mean Sea Level.—As all elevations are derived from mean sea level it is important that this should be accurately determined and that the points selected should be such that the sea level at them will not be affected by local influences. In this connection let me quote again from the report of the

Great Triangulation Survey of India:—"The mean level of the sea is the zero or datum surface from which the elevations of the bench marks of India have been measured. In 1909 a selection had to be made of the tidal observatories, which were to form the basis of the levelling net, and which were to furnish data for the determination of mean sea level. There were three alternative courses open, namely:—

1. One reliable tidal observatory could have been chosen, and the height of the whole level net could have been based upon the mean sea level at this point; or

2. The values of mean sea level, derived from all tidal observatories connected with the level net, could have been introduced into the levelling adjustment; or

3. The results obtained from selected tidal observatories could be retained and those from other observatories rejected.

The first alternative was not considered satisfactory. The mean sea level at any point may be permanently influenced by winds and currents; and the tidal observations may be affected by instrumental errors. At no station does the annual determination of mean-sea-level reproduce the values obtained in former years. As these uncertainties exist, it seemed inadvisable to base the whole net upon the measurements at one port.

"The second alternative plan by which all tidal observations were to be included, was investigated and rejected. The levelling operations have shown that the mean-sea-level in certain confined places, such as the Gulf of Cutch and the mouth of the Hooghly, is abnormal, and permanently deformed. At these points the mean water level differs from the mean surface of the open sea by amounts greater than the probable errors of levelling, and it was considered incorrect to force the levelling into accord with the tidal determinations.

"So long as the error of a determination of mean-sea-level is clearly larger than the error accumulated in the levelling, the rejection of the tidal result may be considered advisable. But in the case of some tidal observatories the evidence is very doubtful. The selection or rejection of tidal stations then becomes a difficult question, and one that can only be settled arbitrarily. It must be remembered, that the tidal stations are required to form the foundations of the levelling net, that they are expected in fact to give to the levelling in their respective localities more reliable values of height than the levelling can bring from any distant tidal observatory. It is futile then to endeavor to test their reliability by means of levelling results, which they themselves are intended to control. We must either accept one or the other as the more correct; we cannot utilize each in turn as the test of the other.

"If the observed difference of elevation between the mean-sea-level at different ports, connected by levelling, is considerably greater than the error to which levelling is ordinarily liable, it may be assumed that the two sea levels do not belong to the same level surface. But no definite conclusion can be drawn, when the observed difference of elevation is only small. In such a case the two sea levels have not been proved to belong to one level surface. The [illegible] be [illegible], and due to the [illegible] having the same [illegible] and effect as the actual difference of sea levels, or to the levelling errors [illegible]

"The selection of tidal observatories on which to base the levelling net has been therefore governed by general principles, and not by any observed accordance of results. It has been settled firstly to retain open-coast stations at which [illegible] annual determinations of mean-sea-level have proved accordant, and secondly, to reject tidal observatories situated in channels, gulfs, creeks, or rivers, and those at which annual determinations of mean-sea-level appeared discordant.

"The variations of mean-sea-level—When we refer to variations of mean-sea-level we mean always variations relative to the level of the land surface. The movements of the earth's crust are of two descriptions—the gradual and the sudden; there are, firstly, the slow imperceptible elevations and subsidences of possible immense areas, and, secondly, the sudden change caused by earthquakes.

"The Branch line of levels from Saharanpur to Mussooree is the only line in India that has, so far as we know, been disturbed by an earthquake. We have moreover no evidence that any of our bench marks have been disturbed by slow gradual movements of the earth's crust;.................. we have the annual determination of sea-level made at nine different tidal observatories, and we have been unable to detect in them any tendency to constant change in one direction. The mean-sea-level has been shown, it is true, to vary annually, but it seems to oscillate from year to year about one mean position."

These conclusions will have to be taken into consideration when determining upon a mean-sea-level datum for the Geodetic Survey of Canada, if it is decided to abandon that of New York, which we take up at Rouse Point.

Progress—and Publication of Results.—Levelling operations are at present being carried on vigorously by this Department; during the last two seasons three completely equipped parties have been in the field, in 1910, 812 miles of completed levelling was accomplished and during 1911, 893 miles. The total amount to date is 2,627 miles, that is to say, this distance has been run forward and the same distance backward, no account being taken of the additional relevelling done.

748 bench marks (all of the copper bolt variety described above) have been established since the beginning of the work, this number does not include any that are known to have been since destroyed, but only those actually in existence and connected to the lines of levels.

The question of publishing the results of the work for the benefit of the public was not taken up till about the beginning of last year, as it was desired to have the work on a sound basis and to have some connections with other datums before doing so. The Chief Astronomer's report for 1910, now in course of preparation, contains the complete descriptions and elevations of bench marks and rail levels at stations from 840 miles in Ontario, Quebec and New Brunswick and the 1911 report will probably contain additional results to the amount of 850 miles or thereabouts.

◆

STANDARDIZATION OF FITTINGS AND VALVES.

At a meeting of the committee of manufacturers on standardization of fittings and valves, held at No. 30 Church Street, New York, N.Y., July 10th, 1912, the "Manufacturers" 1912 schedule of flanged fittings and flanges was adopted to take effect October 1st, 1912. There was practically no opposition among the manufacturers present to the adoption of this schedule, but one vote being recorded against it. Copies of this schedule will be printed and distributed to the manufacturers and the trade generally as soon as possible. New list prices for brass and iron body swing check valves, standard and extra heavy, were adopted at this meeting, to take effect October 1st, 1912, copies of which will be printed and distributed to the trade as promptly as possible.

THE CHARACTERISTICS OF COPPER AND ALUMINUM OVERHEAD LINE CONDUCTORS.

By E. V. Pannell.

The assertion has been made that in the sequence of processes involved in the production, distribution and utilization of electric power the weakest link is in the transmission line; the same being far more liable to electrical or mechanical failure than any of the generating, transforming, or converting apparatus. Whether this statement be justifiable or no, it is certain that until recently considerably less attention and care have been devoted to the line than to the electro-dynamical plant, and only of late has the former received its due share of attention. In this country, of course, long-distance overhead transmission is only in its embryonic stage, and little in the way of operating data is available. When, however, the time is ripe, we shall undoubtedly profit by the experiences of transmission engineers in Europe and America who have accomplished the pioneer work in this field. Such engineers have by no means neglected to study the relative utility of various conducting materials, and it is far from being the claim of the author to have opened up a new subject. The object of this article is, however, to set forth a few rules by the use of which a comparison of line conductors may be readily made, and to attempt a few deductions from the same as far as apply to our British conditions.

In the field at the present day there may be said to be two active competitors as conducting materials, viz., copper and aluminum. In preference to the latter metal in its pure state, alloys have often been experimented with. Bearing in mind that the tensile strength of aluminum may be increased upwards of 60 per cent. by judicious alloying without a very great decrease in conductivity, this would seem to be justified. It is, however, found in practice that no such alloy is as resistant to corrosive effects as pure aluminum, and this disadvantage is sufficient to discount the use of alloys for bare overhead conductors. For abnormally long spans, stranded cables of steel have frequently been used both in Europe and America, but the drawbacks to their general use are quite apparent. To take advantage of the high tensile strength by spacing the supporting structures farther apart would result in so great an expenditure on the latter as entirely to off-set any saving on the conductors.

The comparative physical properties of copper and aluminum have been detailed at length on several occasions, and need not be dwelt on here. Such properties are relevant to this investigation are set out in Table I. below. It should be noted that the physical constants are such as to apply to stranded cables in both cases, as all schemes transmitting appreciable quantities of energy now use stranded conductors. This is more than usually true in this country, where it is doubtful if legislation will permit of the use of such high line voltages as render the use of a small solid conductor preferable to the equivalent stranded cable. Before leaving the question of fundamental properties, it should be mentioned that now that such large quantities of high-grade aluminum are being produced for electrical work, the conductivity and tensile strength can be confidently guaranteed. Conductivity and freedom from corrosion are equally dependent on the purity of the metal, and improvements in production have rendered it possible to place upon the market aluminum of well over 99 per cent. purity.

Table I.—Properties of Copper and Aluminum Stranded Overhead Conductors.

	Copper.	Aluminum.
Relative conductivity %	100	60
Specific gravity	8·95	2·71
Relative weights for equal conductance	100	50
Relative cross-section	100	166
Tensile strength, lb. per sq. in......	60,000	30,000
Factor of safety	5	5
Maximum working stress	12,000	6,000
Modulus of elasticity	12,000,000	9,000,000
Specific extension λ	·00000008	·00000011
Coefficient of expansion α.........	·0000093	·0000130
β = α/λ	116	118
Extension in feet for full working stress, 100 ft. span.	·096	·066
Do. 200-ft. span	·192	·132
Do. 400-ft. span	·384	·264

The enormous outlay called for by the line conductors of a transmission scheme renders the economic question a vital one, and before a comparison such as this is justifiable the competing metal must show an advantage over copper in respect of capital invested. In this connection the diagram shown in Fig. 1 gives a graphical means of estimating the difference of cost between the two metals, yielding the result in terms of pounds sterling by which aluminum is cheaper than copper per ton of the latter. The prices considered are the basis ones for wire in each case. A small circle has been inscribed to represent the approximate prices ruling at the time of preparation of this article (January, 1912), the figures being:—

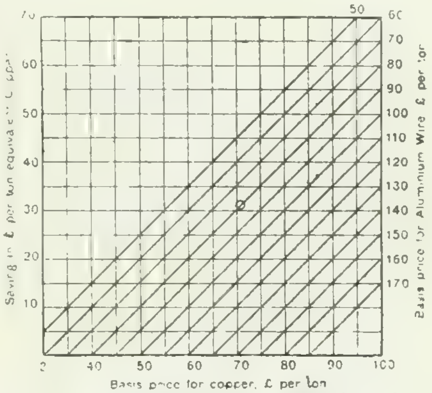


Fig. 1.—Diagram for Estimating the Saving Effected by the Use of Aluminum.

Copper (per ton)	£71 0 0
Aluminum (half ton)	40 0 0
Saving in favor of aluminum........	£31 0 0

The computation, of course, takes into account the fact of aluminum being for a given conductance exactly half the weight of copper. The extra charges for drawing and stranding are a function of the length of the cable, hence on a mileage basis are approximately equal for both metals. The saving as calculated on the above basis is, therefore, unaffected except where multi-stranded cables of small diameter wire are employed.

Turning to the technical problems involved, a starting point is fixed by the Board of Trade recommendations for overhead line construction. Briefly stated, these call for a stress in the conductor not exceeding one-fifth of the ultimate tensile, assuming a temperature of 22 deg. Fahr. and a horizontal wind pressure of 30 lb. per sq. ft. (corresponding to 18 lb. per sq. ft. on the projected surface of the wire). These values together with certain of the physical constants already set forth can by suitable manipulation be substituted in the standard equation for deflection and stress, where—

Deflection at mid-span $\delta = w\, l^2/8\, a\, s$,

and in which w = loading per foot run, lb.; l = span in feet; a = cross-section of conductor, sq. in.; s = maximum working stress, lb. per sq. in. The deduction of this equation from the catenary need not be entered into here.

The loading on the wire (w) is the resultant of its weight w and the wind pressure p—

$$W = \sqrt{w^2 + p^2}$$

and the inclination of the plane in which the conductor will hang is given by—

Angle with vertical $\theta = \tan^{-1} p/w$,

the two forces p and w acting at right angles. In estimating these and other functions it has been found convenient to use a basis as the outside diameter of the cable. A relation between this quantity and the sectional area has been plotted in Fig. 2, and the approximation is very close indeed.

The loading (w) is shown by the curves in Fig. 3, which are plotted from the figures set out in Table II., and in which both of the components and the resultant have been plotted as a function of the cable diameter. The enormous preponderence of wind over weight loading in the smaller sizes will be noted. This, however, only represents abnormal conditions, inasmuch as the specified pressure of 30 lb. per sq. ft. is only realized under extraordinary tempestuous circumstances.

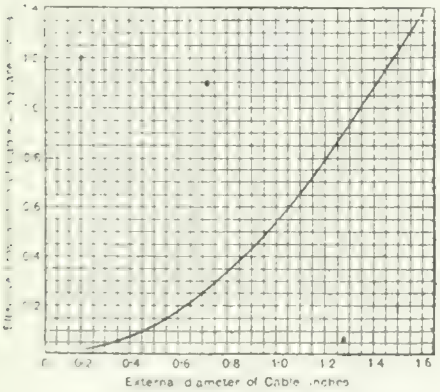

Fig. 2.—Diameter of Stranded Conductors.

As already stated, the formula above given represents the conditions obtaining at minimum temperature, 22 deg. Fahr. With increase of temperature the factor of linear expansion will come into play and the deflection will increase. It is highly important to know the value of the maximum deflection under conditions of high summer temperature, in order that the minimum clearance of the line above ground may be observed and the height of the poles [illegible] in accordance with the same.

Considering, therefore, the effect of a rise of temperature of $t°$ F., if α is the expansion coefficient and l is total length of [illegible], the expansion for a rise of $t° = l \alpha t$ and total length $L_1 = l + l \alpha t$.

Table II.—Particulars of Stranded Overhead Conductors.

Dia. of cable, in.	Effective cross-section sq in.	Weight per ft., lb.	Wind pressure per ft., lb.	Resultant force per ft., lb.
		Copper.		
0.40	0.10	0.40	0.60	0.72
0.60	0.22	0.81	0.90	1.21
0.80	0.38	1.44	1.20	1.80
[illegible]	0.60	2.24	1.50	2.70
1.20	0.84	[illegible]	1.80	[illegible]
1.40	1.15	4.65	2.10	[illegible]
		Aluminum.		
0.40	0.10	0.12	0.60	0.62
[illegible]	[illegible]	0.26	0.90	1.00
0.80	0.38	0.44	1.20	1.30
1.00	0.60	[illegible]	1.50	1.65
[illegible]	0.84	[illegible]	1.80	2.05
1.40	1.15	1.40	2.10	2.50

Now, from the properties of the catenary—

$$L = l + 8\,\delta^2/3\,l \text{ and } L_1 = l + 8\,\delta_1^2/3\,l$$

$$(L_1 - L) = 8\,(\delta_1^2 - \delta^2)/3\,l$$

but $L_1 - L$ = extension for temperature rise $t = l\,\alpha\,t$, hence—

$$l\,\alpha\,t = 8\,(\delta_1^2 - \delta^2)/3\,l \text{ and } t = 8\,(\delta_1^2 - \delta^2)/3\,l^2\,\alpha.$$

It has been thought desirable to manipulate the temperature—deflection equation in the above form in order that a correction for the elastic stretch of the wire may be more readily made. It will readily be seen that as the cable expands with increased temperature the stress is relieved. This reduction of stress, however, gives a diminution of strain, and the conductor will, therefore, extend, due to temperature rise, by an amount which is less than that calculated by the shortening due to reduction of stress. From the other standpoint it will be seen that the temperature rise for a given deflection will be greater than that worked out from the above formula. The correction may, therefore, most conveniently take the form of an increment to the calculated temperature rise. The correction used is a modification of

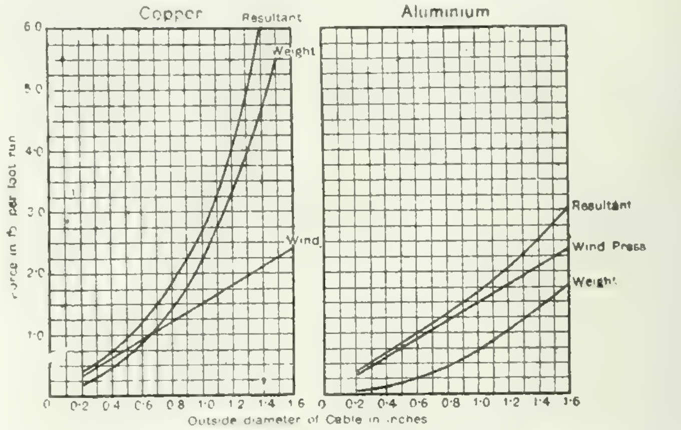

Fig. 3.—Loading Due to Weight and Wind-Pressure on Overhead Conductors.

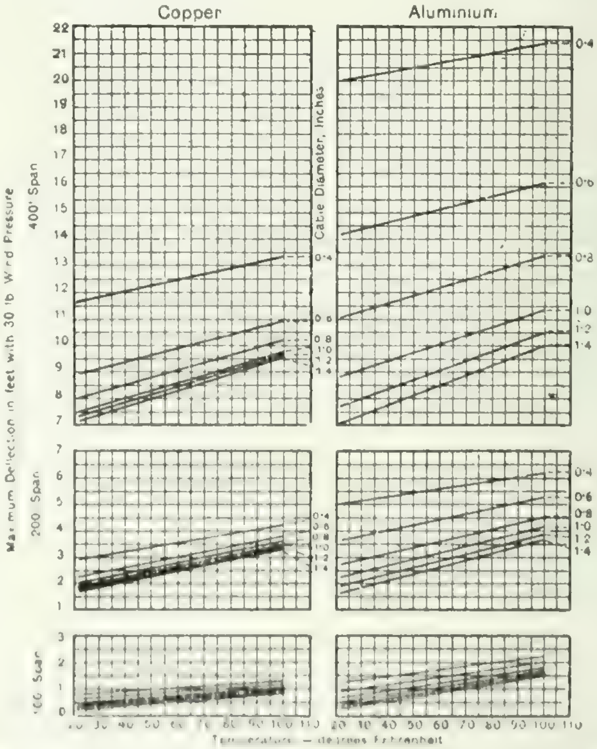

Fig. 4.—Deflections on Overhead Conductors Under Varying Conditions of Temperature.

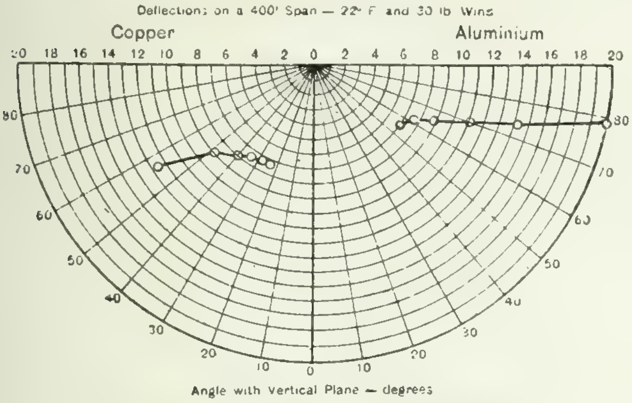
that suggested by Mr. Shields in the discussion on a paper by Burne on "Overhead Constructions" (Journal I.E.E., Vol. XXXI., p. 432), which was read before this Institution some ten years ago.

This correction may be made as follows:—α = per cent. extension per ° F. λ = per cent. extension per lb. per sq. in. stress. $\beta = \alpha . \lambda$.

Now, for a change in deflection $= \delta_1 - \delta$, there is a change in stress $= S_1 - S$, and $S_1 = S\,\delta/\delta_1$; hence the increment for correcting the above temperature $= (S_1 - S)/\beta$, and this should be added to the right-hand side of the equation.

On this basis the curves in Fig. 4 have been plotted and the results tabulated. It will be noted that maximum wind pressure is assumed throughout, hence the deflection is not only considerably above the normal value, but the conductor will be swung out of the perpendicular by a considerable angle. As already shown, the value of this angle is $\tan^{-1} p/w$. It is, therefore, unaffected by temperature, and only depends upon the wind pressure and the weight of wire.



Diameters of Wire (Copper left to right, Aluminium right to left): 0·4, 0·6. 0·8. 1·0, 1·2, 1·4 inches.

Fig. 5.—Polar Diagram Showing the Angle by Which Conductors are Blown Out of the Vertical.

Fig. 5 shows this feature graphically, the values of deflection for a 400-ft. span, at 22° F., and the maximum wind pressure, being plotted in polars.

From curves in Figs. 4 and 5 will be seen, as might be expected, the relatively greater deflections on aluminum conductors, and the greater effect of a given wind pressure. It should be noted, however, that this is largely due to the abnormal value assumed for the latter quantity. Moreover, as will be seen later, a deflection double that of a copper conductor need only call for a pole 10 per cent. higher. The fact that the greater factor in the loading on aluminum cables is this assumed wind pressure, is an advantage on the side of conductors of this material. Under normal circumstances, with moderate winds, the weight of the cable is the more potent factor of the loading, and this value being 50 per cent. lower for the aluminum cables, it follows that the average stress in such will be lower in value. This is by no means an unimportant point, as the lower the average stress on any section, the less is the liability to fatigue.

In predetermining the forces acting on the conductors at the lower temperature limit of 22 deg. Fahr. it is necessary to take into account the wind pressure. In calculating the maximum deflection due to the highest summer temperature, however, wind pressure must be eliminated. Apart from the physical impossibility of a hurricane blowing at 100 deg. Fahr., it is necessary to calculate the maximum deflection in a vertical direction in order to estimate the necessary height of the pole or other supporting structure; in other words, the deflection in still air is what is required. Some manipulation is necessary to allow for this change in the conditions, and the author has found it convenient to use a graphic method for effecting this.

The conditions obtaining at 22 deg. Fahr., as has been seen, are expressed by—

$$\delta = w\,l^2/8\,a\,S.$$

It will be noticed that all save δ and S are constant; hence— $\delta = K/S$, and $\delta\,S = K$.

If, now, the wind pressure disappears, the state of affairs is given by—

$$\delta_1 = w\,l^2/8\,a\,S_1, \text{ i.e., } \delta_1 = K_1/S_1.$$

Ample information is available for the estimating of K and K_1; the latter being obtained, a locus is fixed for $\delta_1 = K_1/S_1$. This curve plotted for a 200-ft. span in aluminum is shown in Fg. 6, whilst at the top of the diagram is the elastic extension curve plotted downwards to represent a contraction. This is obtained simply by multiplying the stress by the elastic constant and by the length of span. The variation of deflection with extension of the cable is calculated from the equation already given—

$$L = l + 8\,\delta^2/3\,l$$

hence a series of deflection curves can be plotted from the values in the elastic extension curve. The points where these lines intersect the $\delta_1\,S_1$ hyperbola show the positions where the catenary and elastic laws coincide and give the actual deflections which the conductor will take up, with the corresponding stresses.

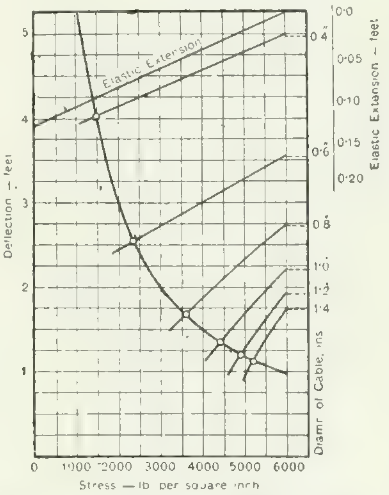


Fig. 6—Graphical Method for Determining the Reduced Deflection, with a Reduction of Stress. Aluminum Cables, 200-ft. Span.

A computation such as this, although somewhat laborious, is the only means of predetermining the actual conditions obtaining when an elastic conductor is used for aerial work. The accuracy of the method depends wholly upon the values chosen for elasticity, and there is room for a considerable amount of experimental work in this connection. Very little reliable information is available respecting the physical properties of stranded cables, and with the broadening of the field of electric power transmission such data must be extended.

The respective deflections on the copper and aluminum cables with and without wind-pressure are shown in Fig. 7. These curves, together with the figures in Table III., summarize all the foregoing calculations, and it will be seen that they are plotted to a base representing equivalent sectional area which, of course, is a function of current-carrying capacity. Thus the two materials are here brought into line on the fairest possible basis for comparison. Analysis of these results is very instructive—it being seen that the maximum amount by which the deflection on an aluminum line exceeds that for copper is about 35 per cent. With smaller sizes of cable than 0.1 sq. in. of course this ratio will increase, but this illustrates the fallacy of the statement frequently made to the effect that aluminum is only suitable for small and unimportant transmission schemes. It is exactly for the large power lay-outs that the advantages are best shown, and the greater the amount of power transmitted the better become both the technical and economic features of aluminum. The only point open to question is, at what section of cable does aluminum become superior to copper? The present investigation is carried down to a section of approximately 1/10 sq. in., or 100 amperes carrying capacity in copper, and it does not seem that any preponderating disadvantage accrues from the replacement of copper by aluminum. If however, the matter were carried further, down to very small cross-sections, then the large deflections necessary owing to allowance for wind pressure would cause trouble in spacing the conductors.

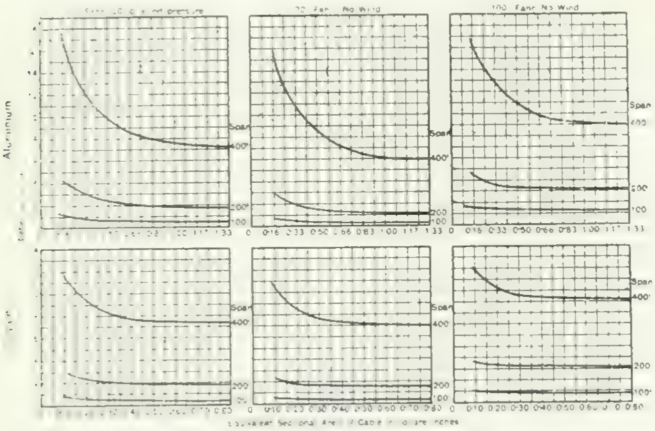

FIG. 7.—DIAGRAMS SHOWING COMPARATIVE DEFLECTIONS ON COPPER AND ALUMINIUM OVERHEAD CONDUCTORS.

In dealing with power transmission at the present day, however, there is a far more valid objection to small-section conductors than the matter of deflection, and that is the phenomenon of corona. It has long been known that high transmission pressures occasion a loss due to brush discharge from the conductors, and more recent investigations have shown that the glow which surrounds the conductor below the limits of the brush discharge is, in itself, a source of considerable loss. The most recent theories on the subject are those of Whitehead ("Losses on Transmission Lines Due to Brush Discharge," Journal I.E.E., Vol. [illegible], No. [illegible]) and Peek ("Law of Corona," Proceedings Am. I.E.E., Vol. XXX., No. 7), both of which are masterly investigations of an extremely involved problem. The feature which has been brought out most strongly is the rapid augmentation of corona loss, with a reduction in the size of the conductor. At working pressures of 80,000 volts and over, this difficulty is a very real one, and the use of tubular conductors has been proposed in order to increase the radius and diminish the liability to discharge. Although such high working pressures are by no means imminent for British transmission schemes, it should be remembered that in our climate corona will form at an appreciably lower voltage than in the drier atmospheric conditions obtaining on the American Continent. There is thus every reason for believing that, other things being equal, the larger diameter conductor will carry a given pressure with a lower corona loss. This is the main reason which dictated the exclusive use of aluminum on the transmission system of the Ontario Commission, which operates at 110,000 volts. The 30 per cent. greater diameter of the aluminum conductor over the equivalent copper is a powerful advantage for high-pressure systems.

TABLE III.—DEFLECTIONS UNDER EXTREME CONDITIONS.

The matter of supporting structures for the conducting line has next to be considered, and on this point considerable diversity of opinion prevails. The single wooden pole has been almost totally displaced in America by the built-up lattice steel tower, mainly on the score of mechanical stability. Whilst this is justifiable in the very large transmission schemes common on the American Continent, it is doubtful whether the advantages of steel towers would be as great in this country. Not only would the cost of such structural steelwork be greater on account of the necessarily lower aggregate weight required, but wooden poles can be obtained in England far superior in durability and scientific design to those hitherto used abroad. For span lengths, such as have been considered in this investigation—viz., up to 400 ft.—the **A** type of pole amply takes care of the stresses due to a double three-phase network, except with abnormally large sections of cable, or with extremely high voltages. Neither of these latter conditions need be anticipated in the immediate future of British transmission schemes, and it would seem that this type of pole is amply sufficient for such projects. In estimating the cost per mile in line, therefore, **A**-type poles have been assumed of appropriate strength and of sufficient height to maintain a minimum distance of 22 ft. between the ground and the lowest point of the wire. The approximate cost of such poles is shown in the curves of Fig. 8, and values have been chosen from these curves for plotting in the "cost per mile" diagrams (Fig. 9). The latter represent the cost per mile of material for a high-pressure double-circuit three phase line, comprising the costs of metal, poles and insulators. Analysis of these curves will show that in no case does the extra cost for the poles on the aluminum lines approach the value of the saving effected on the line conductors.

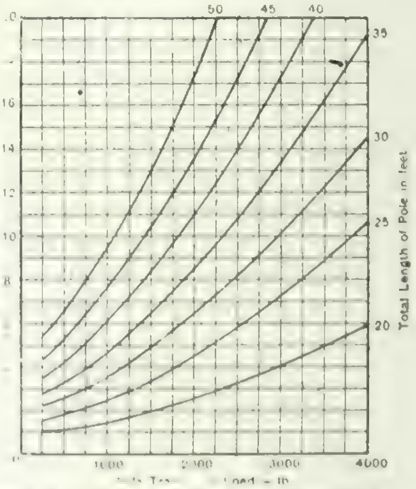

Fig. 8.—Diagram Showing Cost of A-Type Wooden Poles.

This is the most important result, as it refutes the statement often made, that a saving on the cost of line conductors does not imply a saving on the whole expenditure. For very small amounts of power, of course, the cost of poles and insulators will be of relatively greater magnitude, but in such cases the nearest stock size of pole would be requisitioned, and would be pressed into service regardless of the line conducting material.

If it be granted that the poles along the run of the line need to be somewhat stronger and more expensive for aluminum than for copper, the reverse in the case with strain poles, and all structures which have to take the longitudinal stress of the line. The stresses in the aluminum conductors being some 20 per cent. lower than the equivalent in copper, there is much less liability of the poles coming down due to a breakage of one or more conductors. Where, however, steel towers are used they will be designed especially for a copper or an aluminum line. In the former case, the towers will have a greater strength in the direction of the line than the latter, whilst the transverse strength will be in the reverse proportion. Hence, it is reasonable to believe that steel towers for an aluminum transmission line need not cost much more than those for a copper line.

Problems connected with erection are for the most part common to both conducting materials, and for this reason scarcely need treatment in this article. The jointing problem has been solved in both cases by the adoption of the torsion joint, in which the conductor ends are run into a figure 8 or oval section sleeve and twisted up. In straining up the conductors the dynamometer should always be used with reference to a table of stresses. Adjustment by gauging the deflection is unsatisfactory, whatever be the method employed. It should be remembered that the cable should be stressed up to its elastic limit and then let down again, for the reason that if this be not done it will take up a permanent set in the first gale of wind and deflect considerably more than the calculated amount. Neglect of this precaution has been largely responsible for the abnormal deflections reported on certain aluminum lines. This operation, of course, calls for the use of a dynamometer, and can in no wise be accomplished by merely sighting from pole to pole. In this paper deflection instead of stress curves have been plotted, but from the former a table of stresses can be readily prepared and should always be employed on erection work.

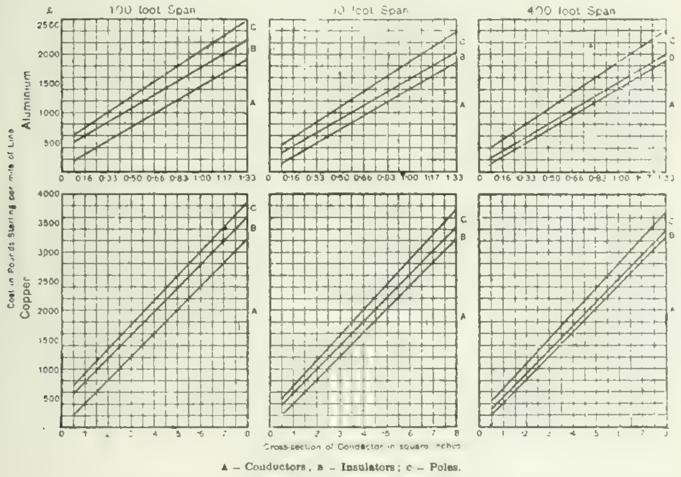

Fig. 9.—Approximate Figures for Cost of Material Per Mile.

In conclusion, the author would say that this short thesis was intended to be by no means an exhaustive treatise on the subject of the title, but merely an example in the use of some simple rules to facilitate comparison between copper and aluminum line conductors. Much of the information relative to the use of the latter metal is here published for the first time, and the author's best thanks are due to Mr. Arthur Jacob, of the British Aluminum Co., Ltd., for permission to use the same.

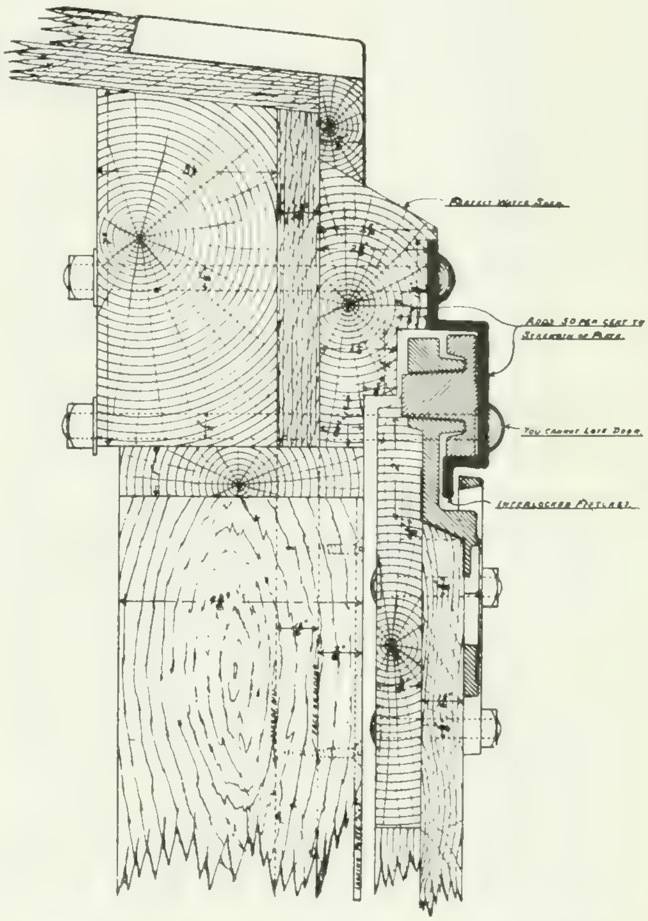
A NEW TYPE OF BOX CAR DOOR.

There has always been a great deal of trouble with box car doors. When doors are made tight they offer considerable difficulty in opening, and when they are made loose they are liable to be lost. With the necessity of making the doors wider the car is liable to be weakened very much structurally. For the above reasons the Chicago Car Door Company, Monadnock Block, Chicago, has recently placed on the market a new type of box car door. The illustrations shown herewith give a fair idea of the design.



Section of Chicago Car Door Showing Interlocking Principle and Watershed.

The track is a rolled steel section about five inches wide, and together with the block by which it is attached to the car, it more than doubles the strength of the plate at the doorway.

As the rolls operate on the inside face of the track they are thoroughly protected from snow and ice and are so arranged that either one of them will travel on the inside top of the track if the door is tilted, either in opening or closing, making it impossible to cramp the door, both rolls always being in contact with the track.

The track also forms an indestructible hood and is a perfect water protection at the top of the door. It projects down on the outside face of the door for a distance unusually great. At the same time it is to be interlocked with the hangers that, if the track is hanging loose on the side of the car, the door cannot be removed without taking out the bolt at the end of the track. This makes it impossible to lose the door off the car without wrecking the latter, a feature which is of interest to every railway official.

On the back edge of the door a spark strip is arranged to interlock with a plate on the face of the door post, similar to others in use, and forms a protection against either sparks or water entering the car at this point.

The bottom of the door is protected by burglar-proof brackets, thousands of which have been in service for several years. These brackets form the guides for the bottom of [illegible] by which they are attached to the sill, are taken out, as the [illegible]

[illegible] door are securely attached, and are intended to take the full [illegible]

PROGRESS OF TRANSCONTINENTALS

Some time during 1914, the Grand Trunk Pacific and the Canadian Northern will be completed across the continent. With three transcontinental railroads, Canada should experience another impetus to further development. At the same time, freight congestion should be relieved and there may also be some adjustment in Western freight rates.

President E. J. Chamberlin, of the Grand Trunk, stated at Winnipeg, that the Grand Trunk Pacific's end of the National Transcontinental will be finished before the end of 1914, and sooner if labor troubles do not interfere. There will be no increased passenger service for the head of the lakes until rights-of-way have been fixed up. The company is getting ready to handle a lot of this year's crop, and to this end elevators and yard facilities are being augmented.

Western advices state that men are working continuously on the big 70-ton steam shovel on the route of the Grand Trunk Pacific from Tofield to Calgary—by the light of the sun in the day time and under the glare of two powerful searchlights at night. It is estimated that the Grand Trunk Pacific will have reached the city limits of Calgary by the end of August, and that steel will be to the waters of the Bow River less than 30 days later.

The bridge over the Skeena, near Hazelton, which has caused delay in laying the rails east of the Skeena crossing, will, it is hoped, be completed by the end of this month. This has been a difficult bridge to construct, the foundations having had to be sunk 25 feet below the bed of the river.

Work has commenced on the large terminals of the Canadian Northern Railway at Montreal, including the tunnel under Mount Royal, and it is officially announced that the Montreal terminal will be completed in 1914. The terminal works are under way at the Pacific coast terminal, Port Mann.

Plans have been completed for the harbor and terminal improvements at Port Mann and work is to be started next month on the first installation of the terminal shops and yards there, the initial cost to be $500,000. The International Milling Company has secured a site on the water front at Port Mann and will begin construction of terminal elevators and a large flour mill on the water front to cost $1,000,000. Mackenzie & Mann have under consideration an application from an English concern for the construction of a dry dock and shipbuilding yards there.

The Canadian Northern's western line is being rapidly extended into the Rocky Mountains this year, and next year will witness the completion of the work in the Yellowhead Pass. Work is proceeding rapidly at all the other points on the system, so as to insure the linking up of the whole road by 1914.

This year 1,053 miles of new road are to be constructed, including several new branches, as follows:—

	Miles.
Montreal to Hawkesbury	58
Ottawa to Ottawa River	32
West from Ruel, Ontario	100
East from Port Arthur	108
Branch lines and extensions in Alberta and Saskatchewan	400
British Columbia	75
Sydenham, Ont., to Ottawa	80
Relaying track on main line west	200

Two thousand men are employed in the construction work, and the approximate amount paid in wages is $1,800,000 a month. In addition to this, 62,000 tons of new steel will be used in laying tracks this year. The probable cost of the tunnel and terminals at Montreal is put at not less than $25,-[illegible] while $[illegible] is being spent for new equipment.

The Canadian Engineer

ESTABLISHED 1893.

HIGHWAY BRIDGES.

The highway bridge question throughout the country is one to which far too little attention is given. A casual inspection of the greater number of bridges now in existence shows that many of them are in exceedingly bad condition through lack of repairs and maintenance. While it is true that a great number of steel highway bridges have been erected during the past few years, particularly in the more thickly populated parts of the country, we feel satisfied that there has been little improvement in the general safety of the bridges. Probably one of the prime reasons for this is the fact that the responsibility of county councils appears to end when they have installed a new steel bridge. Several reasons may be cited to account for this feeling. County councils do not appreciate the necessity for regular and frequent painting of steel structures. They are misled often from the fact of their misunderstanding of the term "permanent," and perhaps here, too, the bridge companies are partly to blame in allowing the misunderstanding to exist. The fact remains that great numbers of highway bridges erected in the last few years are unsafe because no care or maintenance has been put on them. Far too often the design and construction has been contracted for by agents (responsible or otherwise) of the bridge companies, with the result that poor design and extremely light metal has been used. Thus very often the bridge in its initial state has been none too safe.

The remedy for the above condition of affairs appears to be the institution of a rigid system of continuous inspection throughout the country, and this inspection preferably in the hands of the provincial authorities. This inspection should place in the hands of the provincial authorities the power to enforce repairs and regular painting of the structures. Such a system of inspection would repay itself from the start. Under present conditions the life of a highway bridge of light metal without maintenance may be a matter of twelve years or less; with adequate inspection this could be doubled or trebled.

◆

CHICAGO'S ILLUSIVE SEWAGE DISPOSAL METHOD.

It has always been understood that municipalities have prior rights to water for the necessary purposes of domestic water supply and sewerage. It has never been understood that municipalities have any rights to so divert water in such a manner that it is not returned into the watershed or watersheds from which it is taken.

In 1892 the Sanitary District of Chicago commenced a system of sewage disposal by dilution, but not the ordinary method of dilution practised by simply discharging raw sewage into a large body of water. In this particular case a canal or open sewer was constructed, running south from Chicago and discharging into the watershed of the Mississippi. The water used for domestic purposes and pumped from Lake Michigan was thus not returned to its original source, but was diverted. In order to dilute the sewage and produce a less objectionable character than the raw material it was decided that this open sewer required a quantity of new water added from Lake Michigan. Chicago is divided from the watersheds of the Great Lakes and the watersheds of the Mississippi by a comparatively short and low neck of land, consequently it was an engineering possibility to connect the two watersheds and cause Lake Michigan water to flow to the Mississippi.

This open sewer, or canal, as it is now called, was completed in January, 1900, and the Sanitary District of Chicago have continued to use with a permit from the United States Secretary of War to divert 4,167 cubic feet of water per second from Lake Michigan.

Canada and the shipping interests of both continents have watched this peculiar, extraordinary and isolated method of sewage disposal with no little alarm. The principle that the waters of the Great Lakes may be used not only for sanitary purposes in the usual way, but may also be diverted from the Great Lakes and the Gulf of Mexico, is one which causes every interest on the Great Lakes waterways to hesitate and enquire into the stability of the nature of things in general.

The permit of the United States Secretary of War to allow 4,167 cubic feet diversion was alarming to the degree that an extraordinary precedent and principle was admitted, but when the Sanitary District of Chicago recently followed up this permit with a request to the Secretary of War for 10,000 cubic feet, then it appeared that the various interests interested in maintaining a flow of water to the St. Lawrence Gulf had better make some practical enquiries and know best where they stood.

We have before us a bound copy of papers relating to the application of the Sanitary District of Chicago for permission to divert 10,000 cubic feet of water from Lake Michigan to the Gulf of Mexico, published by the Canadian Department of Marine and Fisheries. The papers deal principally with arguments contained in a brief by Mr. Daniel Mullin, K.C., and others who were nominated by the Canadian Government to oppose the application before the United States War Secretary. The chief argument used is the obvious and practical one that any diversion of water will affect the level of the lakes to the extent of the current of diversion, and that not only will the level of the lakes be affected, but, of more importance to navigation, the levels of all the connecting channels, canals and harbors will also be affected. Measurements and computations have shown that a diversion at Chicago of 10,000 cubic feet will lower the levels at various points as follows:—

	Inches.
Lakes Michigan and Huron	7.4
Erie	6.1
Ontario	4.5
Rapide Plat	6.8
Cornwall Canal	5.0
Coteau	5.4
Montreal	10.25
Sorel	6.0

The United States Secretary of War has also his attention drawn to the fact that Canada by treaty has some interest and right in maintaining the levels of the Great Lakes and waterways. The interests connected with navigation and power development are enormous, and we would refer our readers to the published evidence and arguments. It is sufficient to say here that the Chief of Engineers of the United States War Department in a recent communication to the President of the United States, states that the lowering of Lake Erie by one foot would do $[illegible] damage to existing conditions.

This is the most serious and far-reaching question in connection with the International Waterways that Canada has been asked to face. The question of mere dilution of sewage on the part of Chicago is no longer the primary one, but only the secondary.

Mr. Isham Randolph, C.E., of Chicago, in the final [illegible] by any means an engineering appeal, but a crude, impassioned, and essentially egotistical argument (so called) presented to the Secretary of War, states: "Now, I would not leave a doubt in your mind as to what Illinois wants. The question has been raised, For how long a time is the water wanted? As long as water runs down hill or floats a boat, Illinois wants this water. She wants it for the health and life of her people; she wants it for her own water borne commerce and for that of her sister States; she wants it for the power that it will yield; she wants it for the fish that it will produce to feed all the people; she wants it now, henceforth, and forever."

The cat is out of the bag. It is not just a simple little question of the disposal of raw sewage, but a question of a ship canal from Lake Michigan to the Gulf of Mexico, a question of power development by water which is equally the property of both the States and Canada, and also a question of providing sewage-fed fish for all the people.

Well! We are induced to think that Illinois will continue to want, if we are allowed to form any conclusion from the weird nonsense and childish bathos which Mr. Randolph presents as an engineering argument to the Secretary of War. On page 4 of the printed argument we find a paragraph which, as a prime example of egotistical inflation, we quote in full:—

"I am a part of the history of the Sanitary District; for fourteen years and two months I was its chief engineer, the executive head of its construction, and I am, and have been for nearly five years, its consulting engineer, and I know whereof I am speaking!"

Here is another example of the sort of stuff which Mr. Randolph as an engineer presents to the Secretary of War, page 11. Some printed arguments: "Mr. Secretary, you are looking for the truth in regard to this controversy. You must found your ruling upon the bedrock of truth, or else that ruling will be like the house founded upon the sand; when the rain of criticism descends, and the winds of opposition blow, and the flood of indignation come, the decision will fall, and great will be the fall of it."

We cannot but feel that the Church has lost a shining light in the way of a good advertising preacher, and that Mr. Randolph has missed his vocation. He certainly has no pretensions for the legal profession, as he states on page 14: "My knowledge of law is only that absorbed by thirty odd years contaminating association with learned lawyers." We sympathize sincerely with the lawyers of the United States.

We would not quarrel with the extreme egotism and silly verbiage of this would-be engineering brief, if it only contained the truth on which the author desires that the Secretary of War act. But when we find that the principal argument of the brief is to prove that the abstraction of 10,000 cubic feet will in no way affect the waterways and harbors of the Great Lakes, and that the whole of the evidence is based upon the well-known fact that the levels of the lakes fluctuate from time to time, then we must really ask is Mr. Randolph himself sincere, or is he merely perpetrating what is termed a "huge bluff." Four thousand one hundred and sixty-seven cubic feet, the amount of water now allowed, is more than sufficient to form a decent sized river, and there is no practical reason why Chicago should not partly purify its sewage so as to discharge it in a non-putrescible state into such a river.

The statement that 10,000 cubic feet is necessary to the health of Chicago is absolute bluff. The statement that the diversion of 10,000 cubic feet will not affect the lake levels and damage the shipping interests is also bluff. The statement of sewage-fed fish for all the people is also bluff. The statement that power can be developed is not bluff. The idea of the diversion of Lake Michigan waters for purposes of a ship canal to the Gulf of Mexico is not bluff.

THE PANAMA CANAL.

The following statement gives information relative to the Panama Canal on points about which inquiries are being constantly received from many sources.

Type of Canal.—The canal will have a summit elevation of 85 feet above the sea, to be reached by a flight of three locks located at Gatun, on the Atlantic side, and by one lock at Pedro Miguel and a flight of two at Miraflores, on the Pacific side; all these locks to be in duplicate, that is, to have two chambers, side by side. Each lock will have a usable length of 1,000 ft. and a width of 110 ft. The summit level, extending from Gatun to Pedro Miguel, a distance of about 31.5 miles, is to be regulated between 82 and 87 feet above sea level by means of the spillway in the dam at Gatun. The Gatun Lake, which will have an area of 164.23 square miles, will be maintained by earth dams at Gatun and Pedro Miguel. The Chagres River and other streams will empty into this lake. A small lake, about two square miles in area, with a surface elevation of 55 feet, will be formed between Pedro Miguel and Miraflores, the valley of the Rio Grande being closed by an earth dam on the west side and a concrete dam with spillway on the east side at Miraflores.

The approaches from deep water to the Gatun locks on the Atlantic side, and form deep water on the locks at Miraflores on the Pacific side, will be sea level channels, about 7 and 8 miles in length, respectively, and each 500 feet wide.

Length, Width and Depth of Canal.—The canal is to be about 50 miles in length from deep water in the Caribbean Sea to deep water in the Pacific Ocean. The distance from deep water to the shore line in Limon Bay is about 4½ miles, and from the Pacific shore line to deep water is about four miles; hence, the length of the canal from shore to shore will be approximately 41½ miles.

The channel from mile 0 in the Caribbean to mile 6.70 at the north end of Gatun locks will be 500 feet wide; from the south end of Gatun locks to mile 23.50 not less than 1,000 feet wide; from mile 23.50 to mile 26.50, 800 feet wide; from mile 26.50 to mile 27.00, 700 feet wide; from mile 27.00 to mile 31.25, 500 feet wide; mile 31.25 to Pedro Miguel lock (mile 39.36), 300 feet wide, and from Pedro Miguel lock to Miraflores locks, and from Miraflores locks to deep water in Panama Bay, 500 feet wide.

The average width of the channel in this project is 649 feet, and the minimum width 300 feet. The canal will have a minimum depth of 41 feet.

Gatun Dam.—The Gatun dam along the crest will be about 8,000 feet long, including the spillway, or about 1½ miles, and 2,100 feet wide at its greatest width.

The crest of the dam will be at an elevation of 115 feet above sea level, or 30 feet above the normal level of Gatun Lake, and 100 feet wide. The width of the dam at the normal water level of the lake, i.e., 85 feet above sea level, will be about 388 feet.

The central part of the dam will be filled by hydraulic process, protected by rock toes on both sides of the dam. The upper slope on the lake side of the dam will be further protected by 10 ft. thickness of rock. The other parts of the dam will be filled with available material from canal excavation.

In entering the canal from the Atlantic side, a ship will proceed from deep water in Limon Bay to Gatun locks, a distance of 6.9 miles, through a channel 500 feet wide; passing into the locks, 0.78 of a mile in length, the ship will be carried up to an elevation of 85 feet above sea level in three lifts to the level of the water in Gatun Lake; thence for a distance of 16 miles the channel will be 1,000 feet or more in width to mile 23.7; from this point to mile 26.9 the channel will be 800 feet wide; from this point to mile 27.45 the channel will be 700 feet wide; from this point to mile 31.5, near Bas Obispo, the channel will be 500 feet wide; from Bas Obispo to Pedro Miguel lock, through the Culebra Cut, to mile 39.68 the channel will be 300 feet wide. Going through Pedro Miguel lock, 0.37 of a mile in length, the vessel will be lowered to the level of Miraflores Lake, 55 feet above mean tide through which there will be a channel 500 feet wide to Miraflores locks at mile 41.72, thence through the two Miraflores locks, 0.58 of a mile in length, the vessel will be lowered to tide level and proceed through a channel 500 feet wide to deep water in the Pacific at mile 50.0. It is estimated that the time required for the passage of a ship of medium size through the entire length of the canal will be from 9½ to 10 hours, and for larger vessels from 10½ to 11 hours.

Excavation by the French.—The amount of material taken out by the old and new Panama Canal companies was 78,146,960 cubic yards, of which it is estimated 29,908,000 cubic yards will be utilized in the adopted plan of canal.

Total Amount of Excavation.—The following is the estimated excavation required May 4, 1904, based on the present plans for the lock canal:

	Prism	Diversions, etc.	Locks	Dams	Total
Atlantic Division	40,355,636	1,732 882	5,139,304	.	47 227,822
Central Division	100,551,296	1,250,000			101 801,296
Pacific Division.....	41,034,069	....	5,015,459	244,733	46,294,261
	181,941,001	2,982 982	10,154 763	244 733	195 323,379

Comparison Between Lock and Sea Level Projects.—For the purpose of comparison, it may be stated that an estimate has been made from the latest available data, which shows that the excavation required in the canal prism for a sea level canal as of May 4, 1904, would be 319,146,000 cubic yards.

This estimate is for a sea level canal from the —41-ft. contour in Limon Bay to the —45-ft. contour in the Bay of Panama; the channel in Colon Harbor from the seaward end to Boca Mindi to be 500 ft. wide on the bottom, and 41 ft. deep; from Boca Mindi to near the Sosa tide lock, 150 ft. wide on the bottom and 40 ft. deep in earth and 200 ft. wide on the bottom and 40 ft. deep in rock; approach to the tide lock to be 350 ft. wide and the channel from the tide lock to the —45-ft. contour in Panama Bay, 300 ft. wide. This plan includes a concrete dam at Gamboa and a twin tide lock at Sosa with chambers 110 ft. by 1,000 ft. The average width of channel in this project would be 218 ft. and the minimum width 150 ft.

Estimated Cost of Lock Canal Under Construction.—The cost estimated by the present commission for completing the canal is $325,201,000, which includes $20,053,000 for sanitation, and $7,382,000 for civil administration.

These figures do not include the $50,000,000 paid to the new French Canal Company and to the Republic of Panama for property and franchises. Hence, it is estimated that the total cost of the canal to the United States will approximate $375,000,000.

Time of Completion.—While the official date of opening of the Panama Canal has been set for January 1, 1915, it is the intention to allow vessels to utilize the canal just as soon as practicable. Present indications seem to bear out the opinion previously expressed by the chairman and chief engineer of the Isthmian Canal Commission that this can be accomplished during the latter half of 1913, although it is too far in advance at this time to fix any definite date. Shipping interests will, however, be advised as soon as the commission feels assured that vessels can be passed without unnecessary delay.

Material Excavated by the United States.—The amount of material excavated since the Americans took control on May 4, 1904, is as follows:

	Cubic yards.	Monthly average.
May 4 to December 31, 1904	243,472	30,434
January 1 to December 31, 1905....	1,799,227	149,936
January 1 to December 31, 1906....	4,948,497	412,375
January 1 to December 31, 1907...	15,765,290	1,313,774
January 1 to December 31, 1908....	37,116,735	3,093,061
January 1 to December 31, 1909....	35,096,166	2,924,680
January 1 to December 31, 1910....	31,437,677	2,619,806
January 1 to December 31, 1911....	31,603,899	2,633,658

	Hydraulic Fill	Dry Fill		
	Cu. yds.	Cu. yds.	Cu yds.	Cu. yds.
In place April 30th, 1912	10,158,826	9,641,673	545,355	1,172,634
Work in May, 1912.	194,733	227,017	21,782	31,220
Total to June 1st, 1912.	10,353,559	9,868,690	567,137	1,203,854

x 660,598 cubic yards of wet fill were placed in Miraflores dam up to June 1, 1912.

The.figures given in the above table of fill in Gatum dam are in excess of the amount in place, determined from cross-section surveys, due principally to consolidation of material. Up to February, 1912, the surveys showed a difference of 757,068 cubic yards, and this amount should be deducted to obtain the net amount of material in place. An allowance of about 200,000 cubic yards should be made for future consolidation.

It is estimated that the net amount of material in the completed dam will be 22,100,000 cubic yards.

The construction of Gatun dam is being carried on by first building two lines of rock, composed of spoil from the canal and lock excavation, about 1,200 feet apart and parallel to the centre line of the dam. The south of upstream pile or "toe" as it is called, has a height of about 60 feet and the downstream toe about 30 feet. These rock toes confine the body of the dam between them, which is to be mainly of impervious material pumped in by pipeline dredges. At the bottom this impermeable core will have a width of about 860 feet outside of which the body of the dam will consist of spoil, which can be placed with the least expense. Outside of the toes are the waste piles for the spoil of neighboring excavation. These piles will slope down gradually and extend indefinitely, so far as material is available.

Unit Cost of Canal Work (Including Plant Arbitrary Charges).—The average cost of dry excavation in the central division (including the Culebra Cut) for the fiscal year ending June 30, 1911, was 58.80 cents for direct charges, and 4.57 cents for administrative and general expenses of the and general expenses of the Isthmian Canal Commission, making the total average cost 24.33 cents per cubic yard.

The average cost for dredging in the Atlantic end of the canal for the fiscal year ending June 30, 1911, was 22.15 cents for direct charges, and 2.18 cents for administrative and general expenses of the Isthmian Canal Commission, making the total average cost 24.33 cents per cubic yard.

The average cost of dredging in the Pacific end of the canal for the fiscal year ending June 30, 1911, was 25.19 cents for direct charges, and 2.45 cents for administrative and general expenses of the Isthmian Canal Commission, making the total average cost 27.64 cents per cubic yard.

Steam Shovel and Dredge Equipment.—There are now on the Isthmus 100 steam shovels of different capacities, and 18 dredges, the latter being classified as 7 ladder, 3 dipper, 6 pipe-line suction, and 2 sea-going suction dredges.

Force Employed.—In the month of March, 1912, there were approximately 45,000 employees on the Isthmus on the rolls of the commission and of the Panama Railroad Company, about 5,000 of whom were Americans. There were actually at work on April 24, 1912, 36,136 men, 29,354 for the commission, and 6,782 for the Panama Railroad Company. Of the 29,354 men working for the commission, 4,276 were on the gold roll, which comprises those paid in United States currency, and 25,078 were on the silver roll, which comprises those paid on the basis of Panama currency or its equivalent. Those on the gold roll include mechanics, skilled artisans of all classes, clerks and higher officials, most of whom are Americans; those on the silver roll include principally the common laborers, who are practically all foreigners. Of the 6,782 Panama Railroad employees, 831 were on the gold roll.

Finances of the Canal. Appropriations and Expenditures Down to April 30, 1912.

RAILROAD EARNINGS.

The gross earnings of the Canadian Pacific Railway for the past three fiscal years are as follows:—

July 1, 1911, to July 1, 1912	$122,856,000
July 1, 1910, to July 1, 1911	103,525,000
July 1, 1909, to July 1, 1910	94,490,000

The Grand Trunk May statement shows net profit, as follows: Grand Trunk proper, increase £500 sterlin Atlantic, net profit decreased £3,250; Grand Trunk western, net profit increased £23,950; Grand Haven, net profit increased £1,650. The total net profit for the whole system increased £22,850.

The gross earnings of the Canadian Northern Railway for the twelve months ending June 30, 1912, were $19,538,600, as compared with $15,199,200 in the previous twelve months, a gain of $4,339,400.

The gross earnings of Toronto Railway for June were $444,598.91, as compared with $401,185.88 in the corresponding month last year, an increase last month of $43,413.03. In the past five years the street car receipts for the month of June have increased by $153,141.41, and the percentages paid to the city for June have increased by $45,201.17.

Traffic is increasing steadily on the Timiskaming and Northern Ontario Railway, although heavier operating charges keep net earnings from gaining much on last year's figures. The gross earnings for April amounted to $142,525, compared with $118,181 in May, 1911. Operating charges increased from $78,000 to $107,000, leaving a net revenue of $50,869. In April, 1911, the net for the month was $40,467. From the beginning of the financial year on November 1st to the end of April, net earnings amounted to $278,000, compared with $272,000 for the corresponding period last year. A considerable portion of the road's earning revenue this year is represented by ore royalties, the total being $71,900, compared with only $12,391 for the corresponding period of 1910-1911.

The following are the railroad earnings for the week ended June 30th:—

	1911.	1912.	Increase or decrease.
C.P.R.	$2,807,000	$3,293,000	+ $486,000
G.T.R.	1,629,178	1,552,647	— 76,531
C.N.R.	469,700	579,700	+ 110,000
T. & N.O.R.	32,048	33,423	+ 1,375
Halifax Electric	6,311	6,871	+ 560

IRRIGATION PROJECTS OF THE CANADIAN PACIFIC RAILWAY COMPANY IN ALBERTA.

By A. S. Dawson.*

Supplying moisture to desert and semi-arid lands by artificial means is no new thing in the enterprises of civilization, and has been practiced on one portion or another of the globe since the dawn of history.

It was practiced by the Egyptians, Arabians and Assyrians many centuries past; and history records that the flood waters of the Nile were used to irrigate its valleys many hundreds of years ago. The Romans operated vast systems, which are in use at the present time; and the Chinese are credited with having put water on their rice lands by artificial means several centuries before the Christian era.

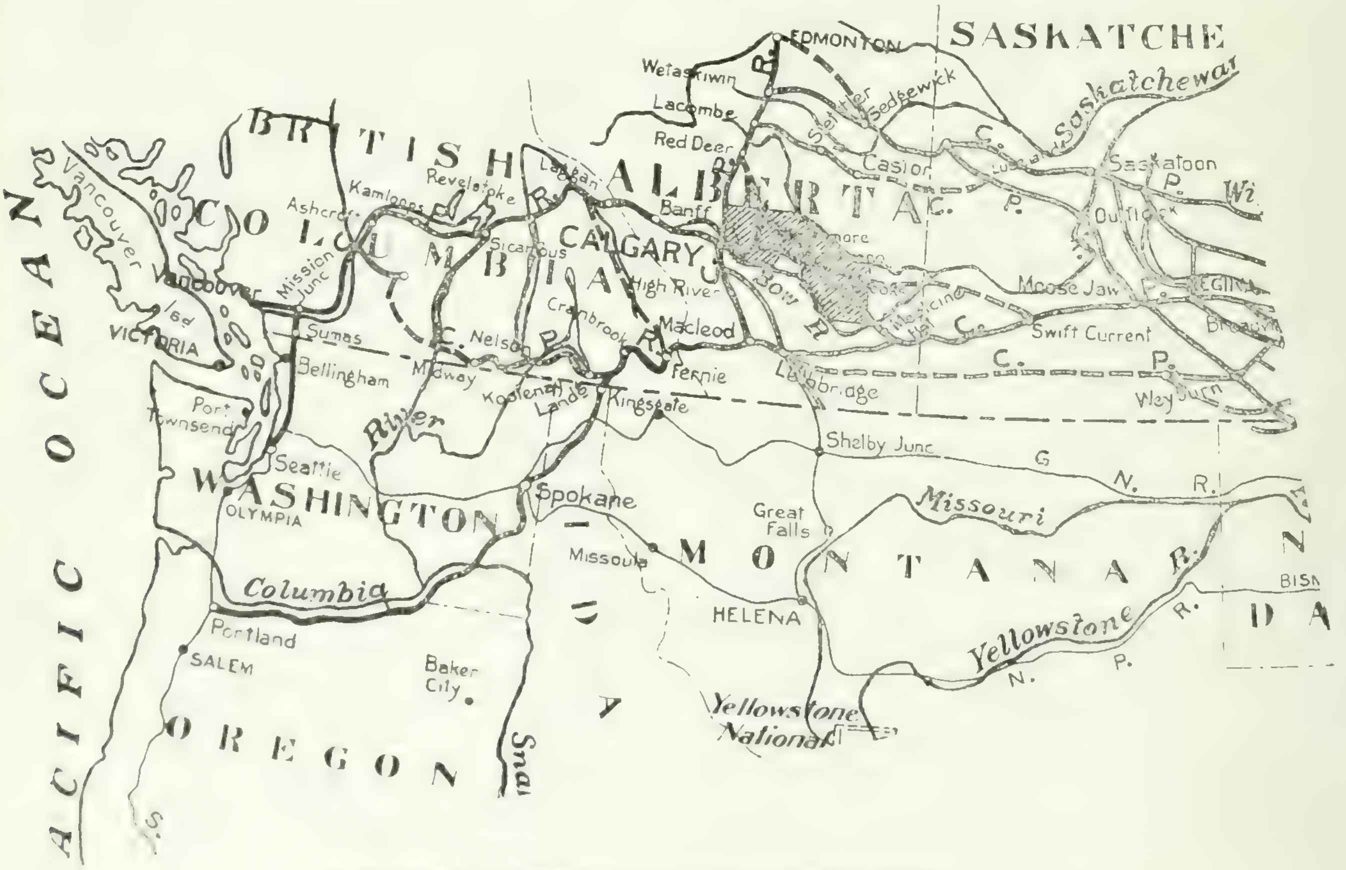
This ancient art had its origin in America in prehistoric times with the Pueblo Indians, who inhabited what are now portions of New Mexico and Arizona.

Mormons settling on the shores of Great Salt Lake were [illegible] ap- [illegible] Western America; and this was shortly followed by the use of ditches in California, originally constructed for placer mining. The results obtained therefrom soon induced settlers in the states [illegible] and Wyoming to resort to [illegible] This was followed by large private enterprises; and the passing in [illegible] of the United States. This vast enterprise, under the direction of the Sec- [illegible] or under construction projects involving an expenditure of over $60,000,000; and has undertaken to complete 35 projects, to serve 3,200,000 acres of land, at an estimated cost of $145,000,000.

The extent to which irrigation is practiced to-day is ofttimes overlooked; amounting as it does to 53 million acres in the Indian Empire, 8 million acres in Egypt, 5 million in Italy, 3 million in Spain, 15 million in the United States, with smaller areas in China, Japan, Australia, France, South America, and elsewhere.

The works providing for the irrigation of these vast areas represent an investment of over one billion dollars; and produce annually crops valued at over that amount.

Irrigation in Southern Alberta may be said to date from 1892, when a series of dry years turned the attention of the settlers to the possibility of aiding the growth of their crops by the artificial application of water. The question subsequently assumed such importance as to warrant its being taken up by the government; with the result that well-considered and comprehensive laws relating to the use of water for irrigation were passed; a system of general surveys undertaken to determine the source and value of available supplies; and the location of the areas where such water could be used to best advantage.



Map Showing Location of the C.P.R. Irrigation Block. Area is Shown in Cross Hatching.

These surveys showed that three extensive areas offered special advantages for irrigation; one containing some 250,000 acres, situated in the Lethbridge district, which could be supplied from the St. Mary's river; a second containing about 350,000 acres lying near the Junction of the Bow and Belly rivers, in townships 11 to 13 inclusive, ranges 11 to [illegible] inclusive; and a third, a much larger one, situated along the main line of the Canadian Pacific Railway, and extending about 150 miles east of the city of Calgary. It is interesting to note that the works to serve all of these tracts have either been built, or are now under construction.

---

*Chief Engineer, Department of Natural Resources, Canadian Pacific Railway Co.

It is the last mentioned project that this paper deals with specifically.

This tract of land eventually passed into the hands of the Canadian Pacific Railway Company, and is now known as the Bow Valley Irrigation Block. It was conceded that its development and colonization along proper lines would add materially to the selling prices of the land; would do away with the uncertainty of getting sufficient moisture for certain crops in certain years; would admit of intensive farming on smaller areas; and would result in settlers being attracted in greater numbers than could otherwise be expected; all of which are the basis of the revenue-producing value of any agriculture country as far as traffic receipts are concerned.

The Bow River heads, as you are aware, in the Bow Lakes on the eastern slope of the Rocky Mountains; and with its tributaries has a drainage area of about 3,800 square miles at Calgary, and about 5,100 square miles at Bassano. It generally reaches its highest stages between June 15th and August 15th of each year, and its lowest stages during January and February. Its maximum flood discharge at Calgary has probably been close to 100,000 second feet, although the hydrographic records for both extreme high and low water are rather meagre.

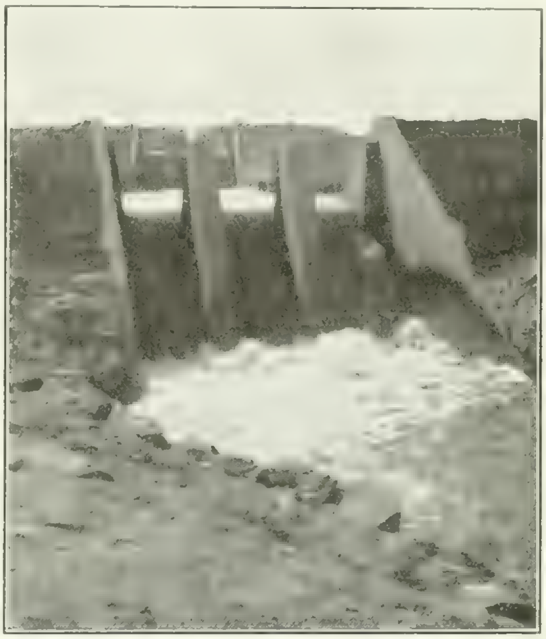
The Block is an open prairie plateau with a general elevation of about 3,350 ft. above sea level at its westerly limits, sloping gradually until a general elevation of about 2,300 is reached at its easterly boundary. Its topography is rolling, particularly in the western portion; whereas large areas of almost level plains are found in its easterly limits. The soil is good, consisting of a heavy black loam and clay subsoil in the westerly portions; and a lighter sandy loam of great depth overlying clay and hard pan in its easterly limits.

It is bounded on the west by the Fifth Meridian; on the south by the Bow River; on the east by the line between ranges 10 and 11, west of the Fourth Meridian; and on the north by the Red Deer River and the north boundary of township 28. Its length east and west is about 140 miles, and it has an average width north and south of about 40 miles. It is intersected by the main line of the railway company, and numerous other railway facilities are being provided in various directions. It contains an area of 4,840 square miles, or 3,097,580 acres.

The precipitation varies considerably from year to year, and decreases easterly as the altitude becomes lower. Meteorological records only exist subsequent to 1886, and are only applicable to the westerly portion of the Block. The average annual precipitation at Calgary between 1886 and 1910 was 15.15 inches; the minimum for the same period being 5.90 inches in 1889, and the maximum for that period 31.90 inches in 1902. The average for the irrigation period of five months, from May 1st to October 1st, covering the same years, was about 11 inches.

Combined Headgates and Drop. Secondary Canal System, Western Section.

· This moisteure, however, is not always available when most needed; and it is a recognized fact that without irrigation certain crops cannot be raised to advantage; and that in any year the certainty of crop production with large yield can only be assured by artificial means.



String of 17 Concrete Drops. Secondary Canal System, Western Section.

Surveys in connection with the project were commenced by the railway company in 1903, and have been gradually extended in detail since that date. As you may understand, this represented a vast amount of work; as an irrigation project demands surveys and examinations far more complete than those for a railway line. Elevation is the controlling feature; and lateral extent or width of country is as important as length; and width, length and height have all to be considered.

Accurate topographical surveys have been carried on by plane-table methods over practically the whole Block at an average cost of about ten cents per acre, on which the complete system has been projected.

On the completion of the preliminary surveys it became evident that the Block naturally divided itself into three sections, which were designated as the western, eastern and central, of about one million acres each; and the work is being carried on along the lines of development in the order named. The western and eastern sections are complete units in themselves, whereas the central section, owing to its general elevation, could only be served by an enlargement of a portion of the trunk lines in the western section.

Western Section.—The western section comprises an area of 1,039,620 acres, of which about 370,000 acres have been brought under ditch. Construction was commenced in 1903 and completed in 1910, and water was first used in 1907. Water for this section is diverted from the Bow River at a point near the present easterly limits of the city of Calgary. The head works are of timber, and are well protected by a pile and timber wall along the river bank, extending 350 feet above and 1,400 feet below the structure. Their sill elevation is 3,353, and they consist of 20 openings, three feet wide and ten feet high, subject to side and top contractions. The gates are of wood, of the straight lift type, and are operated by rack and pinion through a triple reduction gear with a power ratio of 100 to 1, arranged on a movable winch mounted on a travelling truck. It is the intention to replace this structure in the near future with permanent works; and at the same time to build a collapsible dam in the river which will admit of obtaining the full head of about ten feet required, during all stages of the river.

Main canal "A" heads at this structure, its capacity being 2,000 cubic feet per second at full supply of ten feet. Its section varies to suit conditions, its maximum section being 60 feet bed width, 120 feet at the water level, with 3 to 1 slopes, and a grade of .01 per cent. Throughout the greater portion of its length its dimensions are 44 feet bed width, 84 feet on the water line, with 2 to 1 slopes, and a grade of .02 per cent.; which, with an assumed value of n = .025 gives a calculated discharge of 2,050 cubic feet per second. At a point about 2½ miles below the headgates, this canal was crowded close to the river banks by heavy excavation, and at this point a set of escape or regulating gates was provided, with sill elevation one foot below canal grade. This structure is of timber, and consists of four openings 6 ft. by 11 ft. each controlled by wooden gates. These are known as balanced pressure gates, and are so designed that they will rise of their own accord when the head against them is about 5 feet. Each consists of a rectangular barrier working freely between parallel walls without guides. Each gate is hinged to four long arms arranged in pairs, the location of the hinges being so chosen that the weight of the gate is balanced by any required pressure. They are made practically watertight by rubber flashings, and are lifted by an ordinary chain windlass provided with pawl and brake.

At a point about 15 miles below the headgates, the main canal makes a vertical drop of ten feet, where an important timber structure was built. The excessive velocity resulting from this drop was taken care of by the contraction of the opening above to 25 feet, and by a water cushion 5 feet deep below, with an enlargement of the opening to 43 feet terminating in wings. Piling was extensively used in this and all [illegible] structures built on the earth [illegible] of the project.

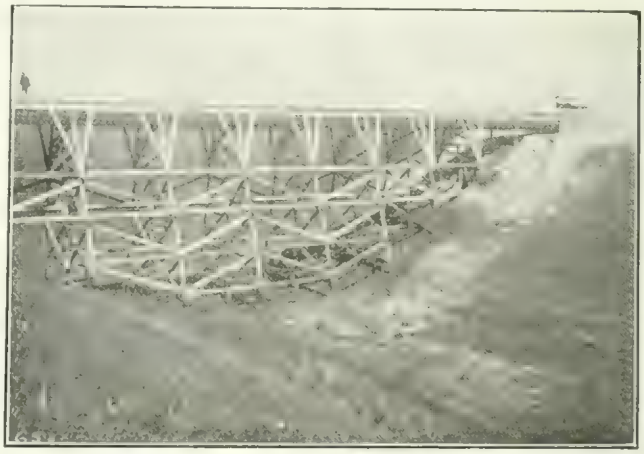
Spillway, East Branch Secondary Canal "C," Western Section.

About two miles beyond this point, or 17 miles from the headgates, the main canal terminates in reservoir No. 1, which, [illegible]

From this reservoir the water is taken out in three secondary canals, known as "A," "B" and "C," having a combined length of about 250 miles. These are each controlled by timber headgates with sill elevation of 3,321.50, and are of a type similar to those described in connection with the main canal spillway.

Numerous large structures are located on all of the secondary canals, including headgates, drops, flumes and bridges.

Secondary canal "A" heads out from the south end of reservoir No. 1, and secondary canal "B" and "C" together are taken out at the north end. Secondary canal "A" at its outlet is 18 feet bed width, carrying 8 feet of water, with 2 to 1 slopes, on a grade of .03 per cent.

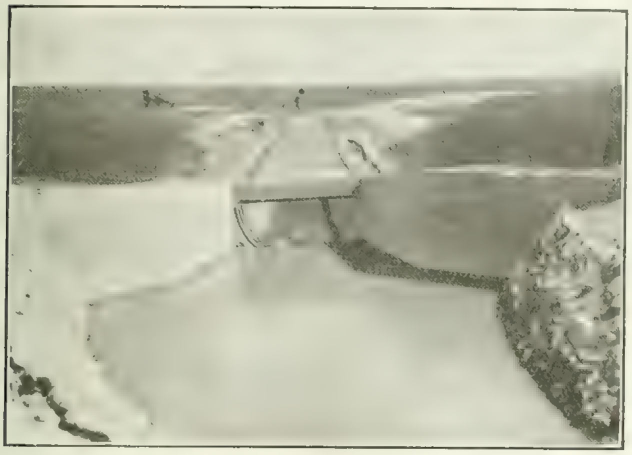


Metal Flume, 7 ft. dia. Secondary Canal System, Western Section.

It drops twice to cross the railway line; and about 15 miles from its head again drops about 30 feet and expands into what is known as reservoir No. 2; at which point its section was changed on account of grade to 22 feet bed width, carrying 6 feet of water, with 2 to 1 slopes, on a grade of .035 per cent. About 30 miles beyond, near Strathmore, it again drops and crosses the railway line, splitting into a north and south branch. North "A" is 10 feet bed width, carrying 3.2 feet of water, with 1 to 1 slopes, on a grade of .06 per cent. South "A" is 18 feet bed width, carrying 4½ feet of water, with 2 to 1 slopes, on a grade of .04 per cent. Both continue easterly to the vicinity of Gleichen, covering lands to the Crowfoot Creek at an elevation of about 2,970.

Secondary canals "B" and "C" together utilize a natural channel for three miles from the north end of reservoir No. 1, and there divide, "B" turning easterly and "C" northerly. "B" is 28 feet bed width, carrying 6 feet of water, with 2 to 1 slopes, on a grade of .025 per cent., continuing for four miles to split gates dividing it into a north and south branch. "C" is 40 feet bed width, carrying 6.4 feet of water, with 1½ to 1 slopes, on a grade of .03 per cent., and serves all the land lying between the Rosebud River and the Serviceberry Creek. At a point about eight miles from its upper end it splits into an east branch, which is 37 feet bed width, carrying 8 feet of water, with 1½ to 1 slopes, on a grade of .035 per cent., and a west branch, which is 12½ feet bed width, carrying [illegible] feet of water, with 1½ to 1 slopes, on a grade of .04 per cent. The east branch utilizes about ten miles of natural channel, in which 175 feet of grade is disposed of. The west branch crosses the valley of the Crowfoot Creek by a wood stave pipe siphon of 53 inches internal diameter and 1,600 feet long, working under a maximum head of [illegible] feet, in which 8 feet of grade is used up

Exclusive of the main canal, secondary canal "B" north branch is the most important waterway in the western section, as it is intended ultimately to be used for the main supply channel to the central section of the Block. After leaving the junction of its north and south branches, it follows a natural channel for about 16 miles, this channel being straightened in places by artificial cut offs. In this distance it falls about 250 feet, the elevation of the split gates being 3,284 and of the headgates at the lower end of the natural channel, known as Weed Creek, being 3,031. At the dam on this channel the canal heads out 18 feet bed width, carrying 4½ feet of water, with 2 to 1 slopes, on a grade of .045 per cent., and extends a distance of 14 miles to a summit with an elevation of 2,998. Before crossing this summit one branch is taken off to serve lands in the vicinity of the south branch of the Crowfoot Creek. After crossing the summit it again splits; the main branch continuing on the north side of an elevated ridge until Summit Lake is reached, which is the controlling point for the central section of the Block, and where a broad low valley of about elevation 2,884 will be crossed by a siphon.



Metal Flume, 7 ft. dia. Secondary Canal System, Western Section.

From the secondary canals the water is again taken out, and distributed through a comprehensive system of distributing ditches, which bring it to each parcel of land to be served.

In the western section of the Block the following mileage of canals has been constructed:—

	Miles.
Main canal	17
Secondary canals	254
Distributing ditches	1,329
Total	1,600

and in addition to the above there are several hundred miles of small ditches constructed by the farmers.

The structures, consisting of headgates, spillways, drops, flumes, bridges, etc., are numbered in thousands; and in their construction 10 million feet board measure of timber, and over four thousand cubic yards of reinforced concrete were used.

In constructing the system in the western section over 10 million cubic yards of material was excavated. Practically all the work was carried out under contract at prices ranging from 12½ cents to 43 cents per cubic yard; the latter price including overhaul on the heavy work. The average price was about 17½ cents per yard. The cost of timber work in place has been slightly over $55 per thousand feet; and of reinforced concrete about $23 per cubic yard; both figures including all material used as well as excavation, trenching, and backfilling.

Central Section.—This section contains 901,740 acres, and it was at first contemplated to irrigate about one quarter of this area. Detailed surveys, however, showed that the cost of serving such an area would be excessive, and at present it is not contemplated to serve more than about 75,000 acres of this section, with an elevation at its westerly boundary of about 2,940.

As previously intimated, this section could only be reached through an enlargement of a portion of the trunk system already constructed to serve the western section of the Block; and due consideration has been given this matter wherever possible by spreading double banks far enough apart to admit of carrying the additional amount of water which will be required.

Up to date the construction of this portion of the system has not been started.

Eastern Section.—The eastern section of the Block contains 1,156,220 acres, of which 440,000 acres are to be rendered irrigable. Most of the land is of a gently rolling character and susceptible to good drainage. The soil for the most part is a rich sandy loam overlying hard pan and shale at various depths.

The idea of the peculiar topographical conditions existing in this section is necessary before the scheme as worked out can be understood. The main watershed of the country between the Bow and the Red Deer River starts, as far as this section of the Block is concerned, at a point on the Bow river locally known as the Horseshoe Bend, about three miles south-west of Bassano, a station on the main line of the Canadian Pacific Railway 83 miles east from Calgary. It parallels the river for a few miles to near the south-east corner of township 18, range 17, west Fourth Meridian, from which point it runs almost due east to a point three miles south-east of Brooks station, thence north-easterly to Tide Lake in township 19, range 11. At the Horseshoe Bend the ridge is cut across by a wide valley, which apparently is

Wood Stave Pipe Syphon, 53 in. dia., 1,800 feet long. Western Section.

an old river channel, the summit of which is only 95 feet above the river bed and about 600 feet from the same. A stream known as the Mat-zi-win Creek has its source in the valley above referred to; and this is the natural boundary between the lands served by the two main branches of the system.

This project as outlined from the surveys takes advantage of a low pass in the watershed referred to, to take water from the Bow River by an intake located at the Horseshoe Bend. A dam is being built across the river at this point, which performs two functions. First, it will raise the water level at the intake, thus enabling the system to command a much larger area of land than it otherwise would have done; and secondly, it reduces the quantity of material to be removed from the main canal heading at the dam. At this point the ordinary low water level elevation is 2,515. The elevation of the canal headgates will be 2,549.6, and normal depth of water in the pool will be 11 feet higher, or 2,560.6. The dam is to be a composite structure, consisting of a long and high earthen embankment on the west bank of the river, and a reinforced concrete spillway in the existing river channel, connected at its easterly end with the canal headgates. Just above the site of the dam the river makes a long bend in the shape of a horseshoe, which gives the locality its name, the dam being located at its toe. At this point the river is approximately 600 feet wide, its north or left bank having a narrow bench immediately at the water's edge and only a few feet above it, beyond which is a cut bank rising over one hundred feet above the bed of the stream. The west or right bank has a gravel beach rising gradually until it forms a tongue between the two legs of the horseshoe. This tongue has a broad flat top several hundred feet in width and rising gradually to the general prairie level, its general elevation near the river being about 25 feet above the bed of the stream.

On this tongue an earth dam is now under construction, to which the spillway structure will be joined. This embankment will have a maximum height of about 45 feet, a total length of about 7,000 feet, and at its highest point is 310 feet in width at the base. Its wetted slope is 4 to 1, and dry slope 3 to 1, the top width being 32 feet, with a free board of 9 feet above normal water level. Provision has been [illegible] filled with bould- [illegible] upper slope [illegible] about one million cubic yards, which material is being transported from the excavation from the main canal across the river over [illegible] The [illegible] of this dam [illegible] gravel and boulders, which in turn overlie dense blue clay.

The spillway referred to is designed to pass over its [illegible]

[illegible]

to be at 15 centres, with every second buttress carried up in the form of a bridge pier. Emergency gates will also be provided in case of necessary repairs having to be made to the main gates.

The spillway proper is a reinforced concrete structure of the so-called "Ambursen" type, consisting of a heavy floor built upon the bed of the stream, and upon this floor are erected parallel buttresses of substantially triangular outline, having a slope on the upstream edge of about 45 degrees. Upon brackets or haunches projecting from the faces of the buttresses and parallel to the upstream edges, is built a concrete slab forming a deck, terminating at the top of the buttresses in a curved crest, and passing down over the downstream edge of the buttresses in the form of an apron suitably curved to correspond as nearly as possible to the path of the overfall flood waters. In front of the dam the floor is being carried downstream a distance of about 75 feet, forming a tumbling hearth. In general, the cross section of the spillway is what is known as the Ogee section, and consists of constructing the downstream face of the dam between the crest and the floor in the form of a reverse curve; the lower edge of this curve being tangential to the floor of the structure, so that the overfalling nappe shall be let down the face of the dam and turned into a horizontal direction parallel to the river bed with the least possible disturbance.

The spillway is founded on a deposit of sand, gravel and boulders, overlying a thick stratum of stiff blue clay.

At the upper and downstream edges of the structure heavy cut-off walls are carried well down into the clay and bonded to the body of the carpet. A concrete apron extends about 12 feet above the upper cut-off wall, and boulder concrete will be placed in the river bed for some distance below the tumbling hearth.

The structure is to be 720 feet in length between abutments, with a maximum height of 40 feet to the overflow crest, above which 11 feet of water will be retained by the gates above referred to. It will contain about 40,000 cubic yards of concrete, and 2½ million pounds of reinforcing steel.

(To be continued.)

BONUS FOR THE PRODUCTION OF QUICKSILVER.

The Mines Department of New Zealand has recently sent out a notice regarding a bonus for the production of quicksilver. We are indebted to Mr. Egerton R. Case, patent attorney, Temple Building, Toronto, for furnishing us with a copy.

Notice is given that a bonus of fourpence (8 cents) per pound will be paid on the production of the first one hundred thousand pounds weight (100,000 lb.) of good marketable retorted quicksilver, free from all impurities, from any mine in New Zealand, on the following conditions:—

That at least one-third of the quantity is produced on or before the 31st March, 1914, and the remaining two-thirds [illegible]

[illegible] hundred thousand pounds (100,000 lb.) of quicksilver has been produced as stipulated to the satisfaction of an officer to be appointed by the Minister of Mines, and on whose certificate alone the bonus will be paid.

[illegible] quired quantities of quicksilver before the dates named, inquiry will be made by the officer above referred to, when, if [illegible]

ORIGINALITY IN BRIDGE DESIGN.

H. G. Tyrrell, Evanston, Ill.

While writing my latest book, entitled "Artistic Bridge Design," which is now in press, my attention has been called to the general lack of originality in the designs prepared by American engineers. In our haste we seem as a nation of engineers to have followed a few accepted types, favored by the various bridge building companies, as the most easily made and usually the cheapest. While it is a fact that America has many of the world's finest bridges, a greater amount of originality can often be found in foreign works, such as the Sukkur and Connel Ferry cantilevers, the Blaauw Krantz, Assopos and Nami-Ti Gorge arches, and many works (Fig. 2) of the earlier engineers such as George and Robert Stephenson. Even in concrete bridges, we find that as early as 1840 European engineers were experimenting with surface treatment when one with a span of nearly 40 feet was built in France by the eminent engineer LeBrun.

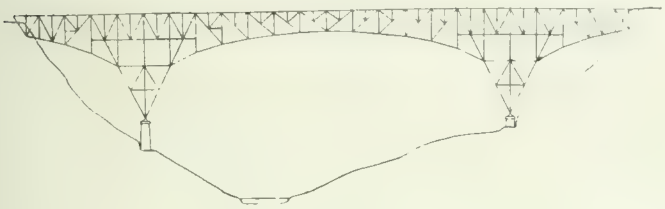


Fig. 1.

It is, therefore, a pleasure on new American works to see the old stereotyped forms laid aside, and plans made with their parts evidently arranged to fulfil their purpose and duties, and not simply copies of some former ones. For this reason the new arch bridge over St. Croix River on the Minneapolis, St. Paul and Sault Ste. Marie Railway (Eng. News, Dec. 28, 1912) is to be commended, not that it is necessarily the cheapest or most appropriate type for the place, but that the designer had the courage to depart from accepted practice by building a series of arches with large rise, instead of a trestle or deck lattice bridge on high piers. In lower outline the bridge is somewhat similar to the central span of a cantilever with an opening of 750 feet, and deck 370 feet above water (Fig. 1) which was designed by the writer in 1906. In these designs, instead of supporting the framing in the usual way on high piers, the chords are curved down to deliver their reactions on comparatively low blocks of masonry. It is gratifying to find that there are many other evidences of improved bridge design in America, where parts are proportioned not only to perform their duties in the most logical manner, but at the same time, to be artistically worthy of preserving and in keeping with other public works of a great nation. Progress in this direction is due chiefly to the leadership of such prominent engineers as Gustav Lindenthal, Chas. C. Schneider, A. P. Boller, Theodore Cooper, and others, and to the eminent architects who have been associated with them in their work, such as Thomas Hastings, Whitney Warren, Palmer & Hornbostle, and Paul Pelz.

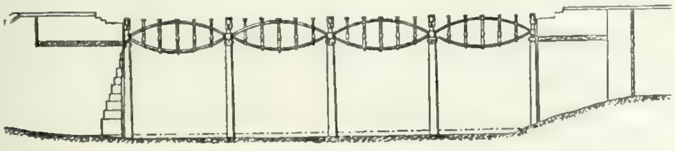

Fig. 2.

OUTLOOK FOR BRITISH COLUMBIA'S MINES

The British manufacturers in their visit to the coast have seen for themselves the possibilities for commercial and industrial enterprises there.

Apart from the interest thus awakened in Great Britain, from where much money comes for development purposes in Canada, the attention of business men in other countries will be attracted. Capital has come to the West from France, Germany and Belgium, and when it is seen that Britain is alive, these other countries will be alert to opportunities. Present trade conditions are in favor of greater commercial relations with western Europe, with the round-the-world steamship lines that have been established in recent years, and in the expansion of commerce that is confidently looked for within the next few years many countries will participate. It was gratifying to note the strong feeling of imperialism in the speeches at the banquet here, indicating that in fututre trade Britain will have the preference. These manufacturers have come, after trips that have been made by several special representatives, press and otherwise, who reported on conditions, and now the principals themselves will be able to judge first hand just what is in Canada and what the possibilities of the future are.

In this letter a couple of weeks ago, mention was made of the prosperous condition of the lumber industry. Note may be made also of the activity in mining. News from the interior is encouraging, and the outlook is better for the operation of metalliferous properties. Prices of silver and lead are very favorable, one of the reasons being the trouble in Mexico, which has interfered with the supply from that country. Higher prices mean better conditions for the low grade properties in the interior of British Columbia, in the Slocan and Boundary, mine owners are very sanguine. Lead has gone up so that the bounty granted by the Dominion has been withdrawn for the time being, and operations are more extensive in the southeastern part of the province.

The Lucky Jim Company has been re-organized and this mine will be shipping as soon as the Canadian Pacific Railway branch line has been extended to the property. Mr. T. G. Proctor, of Nelson, has been successful in interesting capital in the Lucky Jim and the directors now include Premier Roblin, of Manitoba; Hon. G. R. Coldwell, minister of education; Hon. J. H. Armstrong, attorney-general; Hon. Hugh Armstrong, minister of finance, all of Winnipeg; Mr. Joseph Morris, Edmonton; Mr. S. Montgomery, St. Paul, and Col. G. Weaver Loper, Spokane. Mr. A. G. Larson, Vancouver, has been appointed consulting engineer for the company. This is the only one of the fine properties in the Slocan, another being the Standard, which is being developed by Spokane people, and is a money maker.

The British Columbia Copper Company is again among the dividend payers, the latest dividend of three per cent. being an increase of one half per cent. over the dividend of June, 1911. This company is operating full capacity, production running over a million pounds per month, with estimated earnings of about $60,000 per month. The British Columbia Copper Company has an option on the Voight property, comprising several claims near Princeton. Developments there have been highly satisfactory, in the vicinity of Princeton, are many properties and development on a large scale in that district will do much in attracting capital.

The Nickel Plate owners have bonded an adjoining group for $150,000, and an American company, controlled by Mr. C. H. Brooks, has taken over the Kingston group. It has been the wonder of those who know the mineral resources of the Similkameen, why some of the properties with excellent showings have not been taken up by men with capital. The Nickel Plate is in the midst of a number of fine claims, and its earnings show what money is to be made. The Nickel Plate is now paying dividends of twenty-five per cent. per annum, and another quarterly dividend of five per cent. has just been declared. Their plan is to declare three quarterly dividends of five per cent. and a fourth of ten per cent. This company now has an output of about 6,000 tons a month of gold ore, which runs about $12 to the ton.

Reports such as these indicate activity in mining that will result in considerable progress. Metalliferous mining will be the great backbone of prosperity in British Columbia, and while it is coming to the front perhaps only gradually its advancement is substantial.

◆

CANADA'S NEW INDUSTRY.

A substantial addition to the industrial life of Canada has just been consummated by the entrance into the field of the Standard Underground Cable Company of Canada, Limited. The large new plant of this company at Hamilton, Ont., has begun operating several of its various departments and others, we understand, will be started as rapidly as possible.

It will be of interest to our readers to know something of the history of this newcomer into Canadian industrial life. It is not strictly correct to speak of this company as a "newcomer" because its associate American Company has been selling to the Canadian trade for many years, its wires, cables and cable accessories, being well represented on many important electrical installations in the Dominion. Tracing back the new company's lineage through its associated company, we find the latter to have been the pioneer on this continent in making electric cables for underground service. Being the pathfinder, it has always blazed its own trail and has the enviable reputation of having hewn its marks high so that those who follow in its footsteps had to look up, as well as ahead, in their efforts to maintain the progressive pace.

The parent company began the manufacture of lead covered cables and transmission of electricity about 1882 in Pittsburg, Pa. It originated and developed many of the types of cables and manufacturing processes in use to-day and was for years the only manufacturer of such materials in the United States. From the small plant in Pittsburg the company widened the scope of its business and increased its lines of products until now, in addition to the plant at Pittsburg, enlarged from time to time, it has a large aggregate of plants at Perth Amboy, N.J., and Oakland, Cal., a total floor space of over 12 acres. The products that come from these various plants include electric wires and cables of all kinds, for street railway, light and power, signal, telephone, telegraph, fire alarm, and any other service involving transmission of electric current by underground, aerial or submarine circuits. These products also include cable accessories such as terminals and junction boxes, insulating materials, cable splicing tubes, hangers, etc.

It will be seen that while the company's name carries [illegible] chiefly with the manufacture of "underground cable" yet, as a matter of fact, its products include almost every kind of conductor known to the electrical industry. Indeed, in range of products and in [illegible] of great business, this company exceed any exclusively electric wire and cable manufacturer on the American continent and probably in the world.

[illegible] who have built up the [illegible] were instrumental in [illegible] Canadian [illegible] of great interest, as they include many of the most noted American financiers and business men, connected, unless otherwise stated, with the following Pittsburg institutions:

President J. W. Marsh is also president of the Exchange National Bank, one of the oldest financial institutions of Pittsburg. His keen unerring business judgment was signally recognized when he was made chairman of Merchandise Creditors' Committee and that some years ago cooperated most effectively in reorganizing the Westinghouse Electric and Manufacturing Co., of which company, as also of the Colonial Steel Co., he is now a director and Executive Committee member. William Conner, vice-president and manufacturer, also vice-president of the Perth Amboy Trust Co., Perth Amboy, N.J.; Frank A. Rinehart, secretary and treasurer; Albert H. Childs, capitalist and director of the Exchange National Bank; L. W. Dalzell, capitalist and director of the Exchange National Bank; Joseph Wood, first vice-president of the Pennsylvania Lines west of Pittsburg; B. F. Jones, Jr., president of the Jones & Laughlin Steel Co.; J. N. Davidson, president of the Second National Bank of Allegheny; John Moorehead, Jr., of Moorehead Bros. & Co., Inc., of Pittsburg, Pa., and vice-president and director of the Exchange National Bank.

These men saw the wonderful possibilities of the Canadian field and realized that their company's increasing Canadian business could only be adequately fostered by building a plant in the Dominion that would have every modern facility possessed by the United States plants for turning out high quality products and in sufficient volume to keep pace for many years with the increasing demand resulting from the rapid electrical development of Canada. Naturally the choice of location fell upon Hamilton, Ont., the "Electrical City," and there the new plant was erected on a tract of land fronting 400 feet on Sherman Avenue and extending 600 feet along the T. H. & B. Railroad, a location which has every advantage in the way of manufacturing and shipping.

The buildings erected so far include: One three-story brick and structural iron building, 64 x 335 feet; one one-story saw tooth building, 60 x 224 feet; one one-story saw tooth building, 60 x 250 feet; one one-story building, 64 x 90 feet; one one-story building, 30 x 70 feet; also an office building and other small buildings.

The buildings are the very latest type of factory construction, and represent, with their equipment, an investment of $500,000. The plant is electrically operated throughout by power from the Dominion Power and Transmission Co.'s lines. The electric motors are of three-phase, 220-volt induction type. The three testing laboratories are equipped with the most modern and up-to-date appliances for thoroughly testing all products before shipment. These appliances consist of regulating transformers giving voltages as high as 60,000 volts, Wheatstone bridges, D'Arsonval galvanometers, Fisher testing sets, etc., for determining insulation resistances, capacity, conductivity, locating grounds, leaks, crosses or other faults in cables.

True to their policy of employing, so far as practicable, Canadian skill in this Canadian venture, the company employed, in the main, Canadian contractors to erect the new buildings and the Hamilton Bridge Works Co., Limited, supplied the structural iron. The sub-contractors and workmen were all Canadians. The architects were Prack & Berrine, factory experts of Pittsburg and Hamilton.

The officers of the Standard Underground Cable Co., of Canada, Limited, are: President, J. W. Marsh; vice-president and manufacturer, W. A. Conner; vice-president and general sales manager, P. H. W. Smith; secretary and sales manager, W. H. Marsh; treasurer, F. A. Rinehart; assistant to sales manager, H. G. Burd.

BIG BRITISH ENGINEERING ENTERPRISE IN CANADA.

Further details of the Canadian British Engineering Company, Limited, are available. The company's share capital is £205,000 divided into 200,000 7 per cent. preferred ordinary shares of £1 each and 100,000 deferred ordinary shares of one shilling each. The company have made a public flotation of 100,000 of the preferred ordinary shares. Every subscriber when applying for preferred ordinary shares is entitled to subscribe for at par and be allotted one deferred ordinary share for every five preferred ordinary shares allotted to him. The deferred ordinary shares are payable in full on application.

This company has been formed to carry on the business of an engineering supplies and construction company in Canada. It will establish branches in the principal centres in the Dominion, where stocks of standard appliances, spare parts, etc., will be carried. The company will carry out contracts for the supply and erection of all clases of machinery, purchasing the plant required as far as possible from the leading makers of such appliances in the United Kingdom. In cases, where the nature of the work is such that it can be more advantageously carried out by the manufacturers themselves, the company will act for such manufacturers as agents on a commission basis.

The company's capital will be utilized principally in carrying stocks of standard machinery and engineering appliances and in executing contracts for the construction and equipment of engineering works. The directors anticipate that the profits on this portion of the business will be sufficient to provide for a substantial dividend on the whole of the subscribed capital, in which case all profits accruing from the various agency or commision agreements, for which little or no capital is required, will be applicable for surplus dividends on both classes of shares.

The company will have a London office or buying house, through which all communications and negotiations with manufacturers will pass. The London staff will purchase all machinery and appliances required by the company for the fulfilment of its contracts, will inspect plant in course of construction, and generally take the necessary steps to ensure that all such orders receive proper attention.

Sole agency agreements have been obtained by the company from the following firms:—Sir W. G. Armstrong Whitworth and Company, Limited, hydraulic and electric cranes and conveyors, dock and harbor equipments, etc.; Ashmore, Benson, Pease and Company, Limited, gas works plant, etc.; Cammell Laird and Company, Limited, high grade steels, railway and tramway tires and axles, springs, etc.; Dorman Long and Company, Limited, steel beams, angles and channels, etc.; Galloways Limited, pumping plant, mill engines, blowing engines, rolling mill engines, large gas engines and boilers; Power Gas Corporation Limited, Mond gas producers for power and furnace heating and by-product recovery plants; Ransomes, Sims and Jefferies, Limited, agricultural machinery; Sandycroft Foundry Company, Limited, mining plant equipments; and Willans and Robinson, Limited, steam turbines Diesel oil engines and condensing plant.

The directors of the company are as follows:—C. Leonard Agnew, Northwich; W. H. Patchell, M. Inst. C.E., M.I. Mech. E., M.I.E.E., London; Leonard Andrews, M. Inst.C.E., M.I.E.E., London, managing director in Great Britain; William A. Martin, Toronto, managing director in Canada; local board in Canada: William A. Martin, Toronto; Ernest M. Sellon, M.I.E.E., Montreal; Charles Ruttan, Winnipeg; Nicol Thompson, Vancouver.

PULPWOOD CONSUMPTION IN CANADA.

The quantity of pulpwood manufactured in Canada in 1911 showed an increase of 73,801 cords (or 12.3 per cent.) over 1910. In 1911, 672,288 cords were manufactured, as compared with 598,487 cords in the previous year. The value of the wood also increased, with the result that the 1911 product brought to its vendors $4,338,024, as compared with $3,585,154 for 1910, an increase of $752,870. The value of the wood ($6.45 per cord) was greater than it had been for years.

Of the total amount, Quebec consumed in its 28 mills 58 per cent. Ontario used nearly one-third of the total consumption; this province has the highest consumption per mill of any, viz., 12,450 cords. New Brunswick mills were hampered by low water during the year. The consumption of pulpwood in these four mills was 45,824—over twice as much as in the depression of the previous year. Nova Scotia, where only mechanical process of pulp-making is used, in its seven mills consumed 22,221 cords of pulpwood. In British Columbia pulpwood manufacture was still in the experimental stage.

Quebec used four species of wood for pulp, namely, spruce, balsam fir (or balsam), hemlock and poplar. Ontario and Nova Scotia employed spruce, balsam fir and poplar, while New Brunswick used spruce and balsam fir only.

◆

PERSONAL.

MR. MALCOLM R. BOW, of Regina, has resigned his position as assistant bacteriologist for the province of Saskatchewan.

MR. F. A. GOBY, B.A.Sc., has been appointed chief engineer of the Ontario Hydro-electric Power Commission to succeed Mr. P. W. Sothmann, who has just resigned.

MR. J. CHISHOLM has been appointed master of bridges and buildings on the Ottawa division of the Grand Trunk Railway, in place of Mr. J. H. Johnston, promoted.

MR. ALAN FRASER, B.A.Sc., has been appointed to fill the vacancy on the staff of Mr. R. A. Baldwin, district engineer, Mackenzie and Mann, 23 Victoria Street, Toronto.

MAJOR J. E. HUTCHESON, superintendent of the Ottawa Electric Railway since its construction, nearly 21 years ago, has accepted the general managership of the Montreal Tramways Company.

MR. CHARLES WILLIAM DILL, formerly of Toronto, and a member of the firm of contractors, Chambers, Dill and Russell, has been appointed a member of the Board of Highway Commissioners of Saskatchewan.

MR. P. W. SOTHMANN, for six years chief engineer of the Hydro-electric Commission, has resigned and will sever his connection with the Commission on September 1st. Mr. Sothmann is going into private practice. He will organize a firm of consulting engineers under his own name and establish headquarters in Toronto.

MR. JOHN T. DICKERSON, Associate Member American Society of Civil Engineers, has been appointed sales engineer of the Strauss Bascule Bridge Company, in charge of the eastern territory, with headquarters in New York city, succeeding Mr. G. C. Bartram, who has resigned. Mr. Dickerson has been associated with the Scherzer Rolling Lift Bridge Company in their engineering and sales department for the past seven years, prior to which time he was engaged in engineering work for the Burlington, Rock Island and other railroads. Mr. Dickerson is a graduate of the Rose Polytechnic Institute.

OBITUARY.

MR. FRANK T. CONLON, son of Mr. Thomas Conlon, of St. Catharines, Ontario, passed away on July 10th, after a long illness. Mr. Conlon was a graduate of the Faculty of Applied Science and Engineering of the University of Toronto in the class of 1902. For some time he had been employed on the engineering staff of the Welland Canal.

COMING MEETINGS.

THE WESTERN CANADA IRRIGATION ASSOCIATION.—Sixth Annual Convention Kelowna, Okanagan Valley, B.C., August 13, 14, 15 and 16, 1912. Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

THE UNION OF CANADIAN MUNICIPALITIES.—August 27, 28 and 29. Meeting at City Hall, Windsor, Ont. Hon. Secretary-Treasurer, W. D. Lighthall, K.C.

CANADIAN FORESTRY ASSOCIATION.—Convention will be held in Victoria, B.C., Sept. 4th-6th. Secy., James Lawler, Canadian Building, Ottawa.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Second Annual Meeting to be held in Toronto, Sept. 16, 17 and 18.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Annual Assembly will be held at Ottawa, in the Public Library, on 7th October, 1912. Hon. Sec'y, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

EIGHTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.—Opening Meeting, Washington, D.C., September 4th, 1912. Other meetings, Business and Scientific, in New York, beginning Friday, September 6th, 1912 and ending September 13th, 1912. Secretary, Bernhard G. Hesse, Ph. D., 25 Broad Street, New York City.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memorial Museum, Ottawa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W. Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read [illegible] Wednesdays [illegible] winter months, on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairgé; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, Mr. Hugh B. Fergusson, 409 Carter Cotton Bldg., Vancouver, B.C. Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-[illegible] each month, October to April, in [illegible].

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION.—President, Mayor Lees, Hamilton; Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, R[illegible].

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta.; Secy-Treasurer, [illegible], Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer, J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor [illegible]; Secy-Treasurer, W. F. Heal, Moose Jaw, Sask.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, Mayor Mitchell, Calgary; Secretary-Treasurer, [illegible], Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang; Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewit, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President, J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Jas. Anderson, Gen. Mgr., Sandwich, Windsor and Amherst Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman; Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Hon. W. R. Ross, Minister of Lands, B.C. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phoenix Block, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only, unless otherwise noted, at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close — Noted in issue of
7-20—Concrete Arch, Stratford, Ont. ....(P. & S.) 7-4
7-20—Concrete work on bridge and dam at Georgetown, Ont. .... (P. & S.) 7-11
8-5—Electric Generating Machinery, Canora, Sask (S.) 7-18

(Canora specifications are also on file at the office of The Canadian Engineer, Rooms 617-628, Transportation Building, Montreal.)

◆

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

Place of Work.	Tenders Close.	Issue of.	Page.
Arnold's Cove, N.S., dredging	July 17.	July 11.	68
Boisedale, N.S., wharf	July 24.	July 11.	68
Calgary, Alta., three bridges	July 31.	July 11.	67
Edmonton, Alta., gas holder and tank	Aug. 9.	July 4.	67
Edmonton, Alta., steel pipes and specials	July 31.	July 4.	67
Guelph, Ont., bridge and dam	July 20.	July 11.	78
Hamilton, Ont., motors, etc.	July 24.	July 11.	78
Kindersley, Sask., waterworks and electric light	July 22.	June 27.	80

Winnipeg, Man., water meters	July 18.	July 11.	68
Yorkton, Sask., court house building	July 20.	July 11.	68

TENDERS.

Canora, Sask.—Tenders for one crude oil engine and auxiliary and for one electric generator and equipment will be received by H. M. Sutherland, sec.-treas., Canora, Sask., until August 5th, 1912. Specifications may be obtained from the sec-treasurer or from the engineers, or may be seen at the office of Norman A. Hill, 43 Victoria Street, Toronto, and at the offices of The Canadian Engineer, Toronto and Montreal. Bowring and Logan, Engineers, 322 Donald Street, Winnipeg. (See advt. in The Canadian Engineer.)

Clive, Alta.—Tenders for the erection of a school building to be built of brick, will be received until July 20th, 1912. Plans and specifications at the office of F. S. Fulthorp, Secretary-Treasurer.

Edmonton, Alta.—Tenders for gas plant will be received by the City Commissionerss until August 23rd, 1912. Specifications, etc., at the office of the City Gas Engineer, 143 Elizabeth Street, Edmonton.

Islington, Ont.—Tenders for the construction of a 24-inch storm sewer, near the village of Islington, Ont., will be received up to noon of July 23, 1912. Plans and specifications at the office of J. A. L. Macpherson, Engineer, Islington. (See advt. in The Canadian Engineer.)

Kenora, Ont.—Tenders for the erection of a high school building in the town of Kenora, will be received up to noon of Monday, July 22nd, 1912. Plans, etc., may be obtained from E. A. Hudson, H. S. Building Inspector, Kenora. M Seegmiller, Secretary-Treasurer.

Kingston, Ont.—Tenders will be received until July 23, 1912, by City Engineer R. J. McClelland, for one tandem steam roller and one asphalt heating kettle. (See advertisement in The Canadian Engineer.)

Kirkfield Park P.O., Man.—Tenders for the erection of an incinerator will be received until August 8, 1912, by Frank Ness, Secretary-Treasurer, Kirkfield Park P.O., Man. (See advt. in The Canadian Engineer.)

Kirkfield Park P.O., Man.—Tenders for the construction of a reinforced concrete bridge across Sturgeon Creek, will be received until July 19, 1912, by Frank Ness, Secretary-Treasurer, Kirkfield Park, Man. Plans and specifications at the Municipal Hall, St. Charles.

Miniota, Man.—Tenders for the construction of a cement concrete bridge over the Ten Mile Creek in the Municipality of Miniota will be received until July 24th, 1912. Plans, etc., can be seen at the office of the Department of Public Works, Winnipeg, and also at the office of Wm. Howard, sec.-treasurer, Miniota.

North Bay, Ont.—Tenders will be received by Mr. T. N. Colgan, Commissioner of Works, until July 20th, for 30,350 ft. of wire wooden stave pipe, 10 in., 12 in. and 14 in.

Orillia, Ont.—Tenders for the construction of approximately 120,000 sq. ft. of concrete sidewalks will be received until July 29, 1912. Specifications at the office of the Town Engineer, Orillia. W. K. Greenwood, town engineer; E. Long, chairman of committee. (See advertisement in The Canadian Engineer.)

Ottawa, Ont.—The Department of Public Works will receive tenders until July 30, for dredging required at River Bourgeois, N.S. Combined specification and form of tender can be obtained on application to the Secretary, Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders for dredging required at Marble Cove, St. John Co., N.B., will be received at the office of the Secretary, Department of Public Works, Ottawa, until July 23, 1912. Specifications, etc., at the office of the Secretary.

Ottawa, Ont.—The Department of Railways and Canals, Ottawa, will receive tenders until July 18, for the construction of a brick and stone passenger station at Ste. Flavie, P.Q. Plans, etc., at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa; office of the Chief Engineer of the Intercolonial Railway at Moncton, N.B.; and offices of the agents of railway at St. John, Fredericton, Levis and Montreal.

Regina, Sask.—Tenders for the erection of an eight-story steel frame office building for Messrs, McCallum, Hill and Company, will be received by Messrs. Storey and Van Egmond, Architects, Credit Foncier Building, Regina, Sask., up to noon of July 27, 1912.

Regina, Sask.—Tenders for the construction of a reservoir in the village of Cupar, Sask., will be received up to noon of July 20, 1912. Plans, etc., may be obtained from H. S. Carpenter, Acting Deputy Minister of Public Works, Regina, Sask.

Sault Ste. Marie, Ont.—Tenders for the construction of street pavements will be received by C. J. Pim, city clerk, until July 29th. Specifications and plans may be seen and all information obtained at the office of the city engineer. (See advt. in Canadian Engineer.)

St. Thomas, Ont.—The time for receiving tenders for the construction of sewers is extended from July 3rd to July 17th. Plans, etc., at the office of M. H. Baker, City Engineer, St. Thomas.

Sudbury, Ont.—Tenders will be received by the town clerk, until July 29th, for the construction of sewage disposal works, the contractor to furnish all materials and labor. Plans and specifications may be seen at the office of the Engineers, Toronto and Sudbury. Chipman and Powers, engineers; Geo. Elliott, Esq., town clerk.

Vancouver, B.C.—Tenders will be received until July 22, for a school building on the Dawson School Grounds. C. W. Murray, Secretary, School Board.

Vancouver, B.C.—Tenders for the building of the Lumley-Kelowna section of the Okanagan Valley branch of the Canadian Northern Railway will be called for shortly.

The Canadian Northern is about to ask for tenders for the construction of ten railway stations in the Fraser River Valley between Port Mann and Hope.

Victoria, B.C.—Tenders for the following installation will be received until July 22:

(a) Supply and install arc lighting cables on Government Street.

(b) Install arc lighting system on Dallas Road.

Plans, etc., for same can be seen at the office of the City Electric Lighting Station. M. Hutchison, City Engineer.

* * *

CONTRACTS AWARDED.

Fernie, B.C.—The contract for the construction of the new mine rescue station at Fernie, for use in connection with the Draeger system, has been let to W. Grenier, who [illegible]

Fredericton, N.B.—Messrs. Charles and Robert Forbes, of Nashwaak Village, N.B., have received the contract for [illegible]

Guelph, Ont.—The contract for the erection of the new factory of the Dominion Linen Mills has been awarded to Messrs. P. H. Secord and Sons. Messrs. Secord and Sons [illegible]

North Vancouver, B.C.—The city council has accepted [illegible]

Orillia, Ont. [illegible]

[illegible]

Owen Sound, Ont. [illegible]

St. John, N.B.—Tenders have been called for paving King Street and Charlotte Street and awards have been made to Messrs. B. Mooney and Sons and The Caritte-Patterson Mfg. Co., Ltd., as follows: Construction of sheet asphalt pavement on Charlotte Street, from Union Street to south side of King Square—vit. block pavement, $4.44 per square yard; new curb stones, $1.25 per lin. foot; old curb stones, reset, etc., 60c. per lin. foot; reconstruction of one catch basin, $95; repair and regulation of old catch basins, $65 per basin; sheet asphalt pavement, $2.90 per square yard.

Construction of granite block pavement on track allowance King Street, from Charlotte Street to Prince William Street—granite blk. pavement, $4.25 per square yard; new curb stones, $1.25 per lin. foot; old catch basins redressed, 60c. per lin. foot; construction of three new catch basins, $95 each; repair and regulation of old catch basins, $65 each; bituminous macadam pavement, $1.85 per square yard.

Toronto, Ont.—The Advisory Industrial Committee of the Board of Education has appointed the Canadian Domestic Engineering Co., of Toronto and Montreal, sanitary engineers in connection with the erection of the new Central Technical School.

Toronto, Ont.—The tender of The Toronto Type Foundry, of $1,157.25, for a printing plant, was accepted.

Vancouver, B.C.—The Northern Construction Company has been awarded a contract for grading the proposed railway yards of the Canadian Northern at Port Mann. The cost will be about $150,000. W. G. Swan, divisional engineer, will supervise the carrying out of the railway improvements.

Victoria, B.C.—A contract has been let to Messrs. Williams, Trerise and Williams for the erection of a temporary office structure for the Provincial Government while new additions to the Parliament buildings are being completed. Cost, $8,500.

Weston, Ont.—At a meeting held on the 10th day of July, 1912, to consider tenders for the construction of a storm and sanitary trunk sewer, the contract was awarded to Messrs. Campbell, Lattimore and McAllister, of Toronto, for $74,481.75. The other tenders were:

Mr. Connolly	$100,804.00
James Bogul	100,902.10
J. M. Scott	85,209.30
Fry and Thorold	77,274.00
Proctor and Fullerton	95,573.25
J. Rowland McLaren	80,424.05

* * *

RAILWAYS—STEAM AND ELECTRIC.

Port Arthur, Ont.—The city council is considering a route for the belt line for the street railway. The line will be about six miles long.

Victoria, B.C.—The Great Northern Railway will shortly start construction of a large wharf at Sidney, Vancouver Island, B.C.

Brantford, Ont.—The ratepayers voted in favor of assisting in a financial manner the directors of the Erie and Northern Railway.

Southern British Columbia.—The Canadian North Eastern Railway Company (the Portland Canal Short Line), has secured the approval of the provincial Minister of Railways for its location plan of the main line from a point 13.5 miles from the town of Stewart to the confluence of Naas and Blackwater Rivers, a distance of about 91.5 miles.

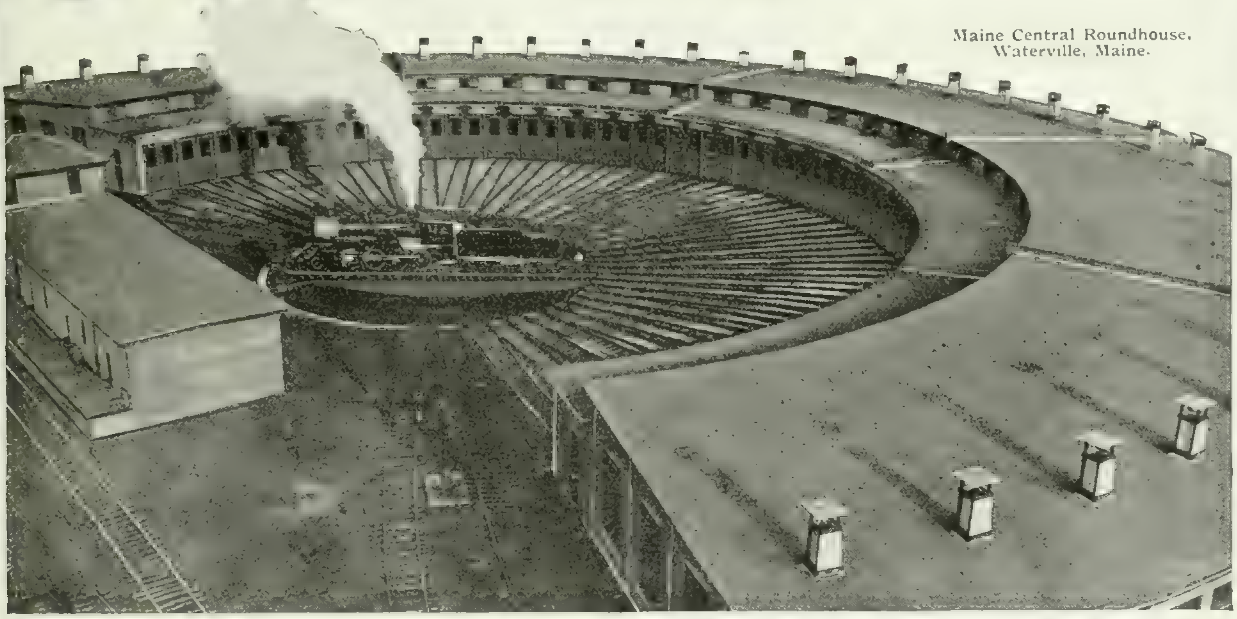
COPY OF CANADIAN ENGINEER WANTED.

Copies of the Canadian Engineer of April 25th, 1912, are wanted. Parties sending in copies will have the usual extension of one month added to their subscription.

Barrett Specification Roofs



Maine Central Roundhouse,
Waterville, Maine.

THE RAILROAD TEST.

THE hardest kind of a building to roof successfully and economically is a railroad roundhouse.

Such a building is exposed to heat inside, condensed vapor from above and below, as well as acid fumes of coal smoke and the constant dropping of cinders and sparks on the surface. All this, in addition to the ordinary wear and tear of the weather.

Only one type of roofing can stand up under such conditions successfully and that is a Barrett Specification Roof.

Its low cost makes it attractive to begin with and the fact that there is no maintenance expense such as painting or coating, makes the net cost per year of service far below that shown by any other roof covering.

The reasons which make Barrett Specification Roofs particularly desirable for roundhouses make them even more desirable and economical when used on manufacturing plants, warehouses, apartments, in fact, on all flat-roofed commercial structures.

Every architect, engineer and owner should have a copy of The Barrett Specification with tracings for use in future building plans and we are pleased to mail same free on request to our nearest office.

Special Note

We advise incorporating in plans the full wording of The Barrett Specification, in order to avoid any misunderstanding.

If any abbreviated form is desired, however, the following is suggested:

ROOFING—Shall be a Barrett Specification Roof laid as directed in printed Specification, revised August 15, 1911, using the materials specified, and subject to the inspection requirement.

THE PATERSON MANUFACTURING CO., LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER ST. JOHN, N.B. HALIFAX, N.S.

LIGHT, HEAT AND POWER.

Kingston, Ont.—The city council have decided to spend $50,000 on extensions of the steam plant to develop electric power and to extend the city's lines to Portsmouth village.

Kingston, Ont.—The Civic Utilities Commission of this city propose installing a new electric generator. This will necessitate increased steam capacity, including auxiliary, at an approximate expense of $50,000. Mr. C. C. Folger is the general manager of the Civic Utilities Department.

Montreal, Que.—The E. B. Eddy Company has decided to erect a hydro-electric power plant which, when completed, will be one of the largest self-owned industrial power plants in the world. Excavation has already been made, and the concrete retaining walls built for the generating station. The new plant will obviate the necessity of purchasing power from outside sources, and will centralize the entire water power system of the company. The consulting engineer for the project is Mr. Wm. Kennedy, jr., of Montreal, with Prof. L. A. Herdt, of McGill University, acting in an advisory capacity. Mr. Bradley is superintending the excavating and concrete work for the E. B. Eddy Company, and Mr. W. C. Baldwin is the electrical superintendent.

Quebec, Que.—Fire caused by lightning completely destroyed the power plant of the Quebec and Jacques Cartier Electric Company at St. Gabriel de Brandon. This plant, which could develop 2,000 horsepower, gave light to a part of the city of Quebec. The loss is estimated at about $50,000.

Toronto, Ont.—The Toronto Power Company have placed survey parties in the field to locate the towers on the duplicate transmission lines between Niagara Falls and Toronto. Mr. R. J. Fleming is general manager.

Welland, Ont.—Welland town will on August 6 vote for the Hydro-Electric by-law to expend $45,000 on a new lighting system in the town. Thirty-year debentures will be issued to pay the costs of same.

◆

GARBAGE, SEWAGE AND WATER.

Calgary, Alta. — Commissioner Graves is preparing plans for an alternative scheme to the gravity system for pumping water for the city from the Bow River, the cost of [illegible] about $[illegible].

Fergus, Ont.—The municipal council have engaged the services of Mr. Peter Gowan, of Galt, to install a water works in that town.

Ottawa, Ont.—The plans, specifications and estimates for the new civic waterworks purification plant will be ready very shortly for submission to the city council.

Ottawa, Ont.—City Engineer Ker has been authorized to have the necessary surveys made and plans and estimates [illegible] two new units to the city's pumping plant, each of which would have a capacity of at least 8,000,000 gallons per 24 hours.

Ottawa, Ont.—A sanitary survey of the river above Ottawa is being made by men acting under instructions from Dr. Shirreff, medical health officer. He is of the opinion that [illegible] of the city's water supply is due to the unsanitary methods of people living along the river banks, [illegible].

Parkhill, Ont. [illegible]

Port Mann, B.C. Negotiations are being conducted between [illegible]

Toronto, Ont. The Municipal Works Committee are [illegible]

Toronto, Ont. [illegible]

BUILDINGS AND INDUSTRIAL WORKS.

Amherst, N.S.—The management of the Amherst Malleable Iron Company, a sub. company of the Canada Car and Foundry Company, will erect a new building 250 feet by 100 feet.

Berlin, Ont.—D. Lorne McGibbon, president of the Canadian Consolidated Rubber Company, Montreal, announces that his concern has accepted the $25,000 bonus offered by the Town Council to erect a $1,000,000 auto tire plant here.

Brockville, Ont.—It is reported that the management of the Richelieu and Ontario Navigation Company will make extensive alterations to the Frontenac Hotel.

Camrose, Alta.—Rev. T. T. Carlson, as president of the Alberta Norweigan Lutheran College Association, announces that building operations will be commenced in the near future.

Fort William, Ont.—Four by-laws were submitted on July 10th, and all were endorsed. They are as follows:—The Canadian Car and Foundry Co. is to build a plant at a cost of $1,000,000. The A. M. Nanton starch and glue factory is to be erected at a cost of $400,000. The H. D. McKellar Building Co. is to build a plant at a cost of $150,000. The Great West Wire Fence Co. plant is to cost $100,000.

Fort William, Ont.—Mr. J. A. Kilpatrick, general manager of the Canadian Iron Corporation stated that plans which have been prepared for an enlargement of the plant will necessitate an expenditure of about $250,000.

Hamilton, Ont.—Report states that the Bank of Toronto has secured a site on James Street, for the purpose of erecting a bank building. The amount involved in the transaction is $70,000.

Moose Jaw, Sask. — A report states that the Canadian Pacific Railway are making preparations for the erection of a $750,000 depot in this city during the early part of 1913.

New Westminster, B.C.—The management of the British Columbia Electric Railway have purchased a plot of ground and propose erecting a new car shop. The present plant is to be used entirely for the repair of cars.

North Vancouver, B.C.—With the opening up of a means of communication to the large zinc deposits of the Western Dominion Land and Investment Co. at the head of Lynn Creek, there is a possibility that a smelter will be established in North Vancouver for the smelting of the ore and the manufacture of zinc products. It is thought that a plant to cost between $120,000 and $150,000 will be established.

Ottawa, Ont.—Messrs. Grant-Holden-Graham, Limited, a wholesale manufacturing firm of this city, intend to commence soon the erection of a two-story addition to their building. They also contemplate the erection of a new building at a cost of approximately $150,000.

Ottawa, Ont.—The proposal of the Federal Government regarding the erection of additional buildings. The scheme is a very large one as it is intended to erect about six at a cost of $20,000,000. A report states that the Canadian Prime Minister will engage an expert in Great Britain for this work.

Port Arthur, Ont.—Engineers for the Ontario and Western Car Co. are laying out the grounds for the construction of 15 large buildings which will be a part of the equipment for construction of cars.

Port Arthur, Ont.—St. Paul's Presbyterian Church have begun excavation for basement of the new church. Hood and Scott are architects.

Port Arthur, Ont.—The federal government are making preparations for the erection of a grain elevator adjoining the structure of the Canadian Northern Railway.

Port Colborne, Ont.—The Dominion Government propose to increase the capacity of the grain elevator at this point.

Toronto, Ont.—The Government has drawn up plans for the new asylum at Whitby, which will cost approximately $[illegible]. It was [illegible] that buildings will be constructed of [illegible] taken from the provincial prison farm at Guelph.

Toronto, Ont.—Construction work has been commenced on a new dry dock for the Polson Iron Works. Mr. David [illegible] has undertaken the contract of erecting this structure.

Victoria, B.C.—By-laws for the raising of $500,000 for the erection of a new city hall and $715,000 for necessary expenditures for school purposes are under consideration.

Victoria, B.C.—Construction work has started at Granby Bay on the 2,000 ton custom smelter to be erected by the Granby Consolidated Mining and Smelting Co. It is estimated the new plant will cost $1,700,000.

Winnipeg, Man.—The Exhibition authorities have taken definite steps in the matter of additions and extensions to the buildings of the fair grounds for next season. The work includes an extension to Main Street, $30,000; improvements in the Arts and Museum section to cost $12,000; and remodelling the train sheds at a cost of $20,000.

◆

BRIDGES, ROADS AND PAVEMENTS.

County of Wentworth, Ont.—Road Superintendent Taylor, following a trip through Wayne County, Michigan, U.S.A., has advocated the use of concrete roads for this portion of the country. He will seek permission to put down a demonstration road near Stoney Creek at a cost of $1,000 to show the merits of concrete construction.

Toronto, Ont.—The Municipal Works Committee have decided in favor of steel in place of concrete for the proposed Bloor Street Viaduct.

York County, Ont.—The members of the York County Highways Commission made an inspection of the roads coming under the jurisdiction of that body.

The concrete roadway extending along the Lake Shore Road from the city limits to Mimico Creek has been finished. The work on the other thirteen roadways was found to be well advanced.

◆

FIRES.

Chatham, Ont.—A fire at Tilbury destroyed a livery stable, grist mill and the town pumping plant, with a loss of nearly $22,000.

Pictou, N.S.—The plant of the Atlantic Milling Company was destroyed by fire with a loss of $28,000.

◆

CURRENT NEWS.

Berlin, Ont.—The management of the Canadian Consolidated Rubber Company have accepted the $25,000 bonus offered by the town council, and will proceed with the erection of a $1,000,000 plant. D. Lorne McGibbon is president of this company.

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending July 2nd, 1912:

An English firm are in the market for supplies of aluminium in flat sheets about 29g, frosted on one side, and would like to hear from Canadian manufacturers.

A London firm of roller-bearing manufacturers wish to get into touch with a first-class firm at St. John, N.B., to represent them there; they are also desirous of being represented at Fort William, Ontario.

From the branch for city trade inquiries, 73 Basinghall Street, London, E.C.:

A London company manufacturing billiard tables would be glad to get into correspondence with Canadian importers.

NEW TECHNICAL PERIODICAL WANTS AUTHORS.

"Steam Machinery," a monthly magazine of men, machinery and methods, intended especially for the lumberman, the contractor, the railroad-builder and the excavator will commence publication before the end of this year.

The magazine will contain departments devoted exclusively to each of the above, and will publish therein articles of interest to those engaged in these various lines.

Contributions of a technical or amusing nature are invited on anything pertaining to the above. All articles submitted must be in typescript, and accompanied by a stamped addressed envelope for return in case of non-acceptance. All articles submitted will be accepted or rejected within a month from the date of receipt.

Accepted articles will be paid for immediately after publication, not at a word rate, but at a rate determined by their interest and value and by the originality of the thought contained in them. The magazine will be edited for the Clyde Iron Works of Duluth, Minnesota, by Charles H. Mackintosh, to whom all articles should be submitted.

◆

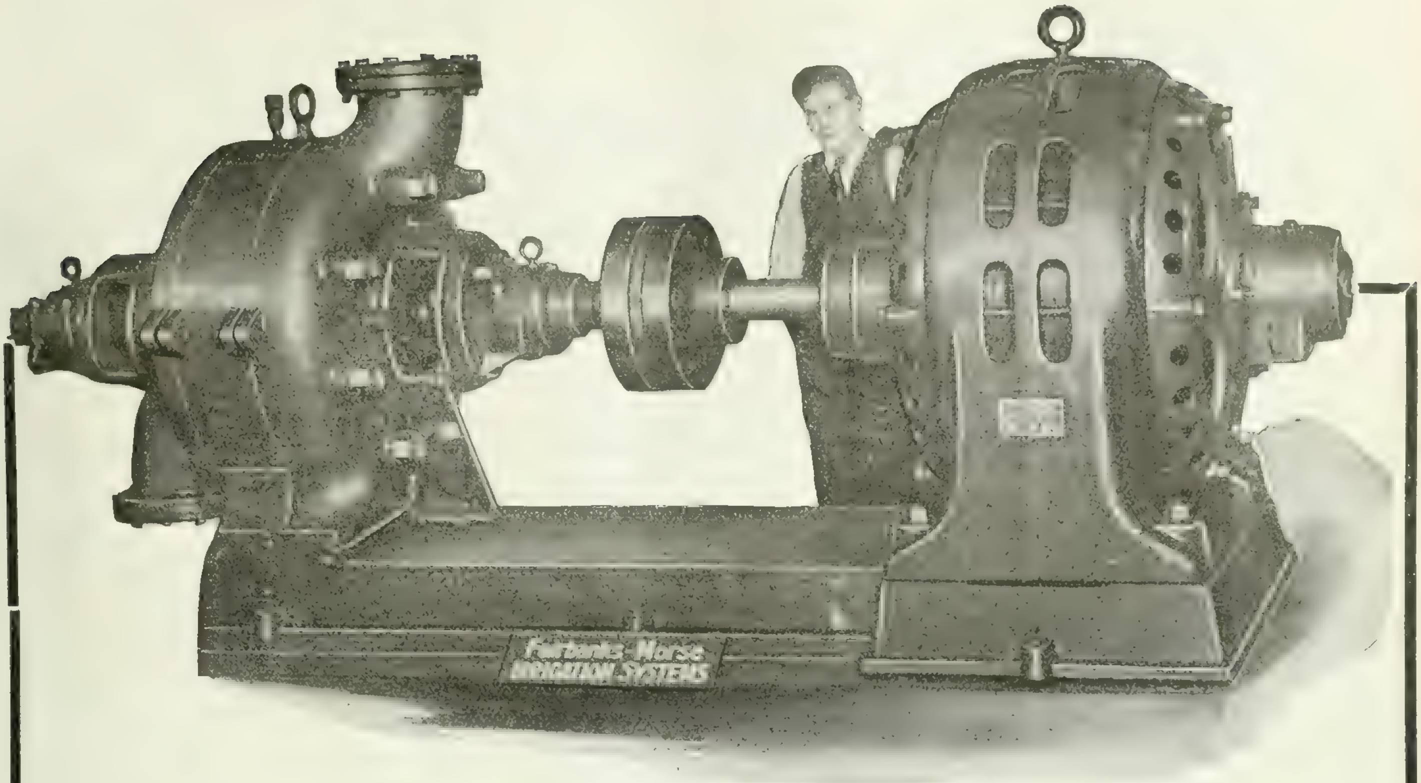
NEW TIMBER MARKS IN WESTERN CANADA.

The timber department of the Provincial Government of British Columbia have issued an entirely new system of private marks for lumbermen, cancelling the old marks as fast as the new marks are given out. In order to put the new system into practice, and to see that it is properly enforced, the department despatched Inspector Wm. Black on the government launch R. J. Skinner for Knight's and Bute Inlets, with instructions to visit all the lumber camps in the north. Capt. Nye was also despatched on a similar errand on the department's launch Kiora, with instructions to visit the camps at Jarvis Inlet, Texada Island, Hornby, Denman's and other islands in the vicinity.

The new system is designed to render less difficult the task of distinguishing the logs cut on licenses, leases, crown grants, etc., and to show which logs are eligible for export and which are not. At present the larger lumber companies are cutting on all manner of grants, leases and licenses, and mark all their logs with the same mark, no matter from which source the logs may come. This causes great confusion, as the royalties and privileges vary with the various terms of leases and licenses, and the department have to largely depend on the word of the companies' employees given on affidavit as to the origin of the various classes of logs.

◆

The municipal council of the city of Winnipeg made an interesting exhibit at the Canadian Industrial Exhibition which proved to be one of the most attractive and instructive exhibits in the fair. There was in operation a complete model of the power plant at Point du Bois, on the Winnipeg River. The water was shown flowing down and operating the turbo generator that keeps the majority of Winnipeg homes supplied with light and other electrical conveniences. Alongside of this demonstration, a large booth has been equipped with all the electrical appliances known to lighten [illegible]



The Largest Direct Connected Centrifugal Pumping Unit in British Columbia.

The Vancouver Power Company have recently installed at their works at Coquitlam Dam, B.C., the largest direct connected centrifugal pumping unit in British Columbia. This outfit is to operate in parallel with a number of other pumps that are to furnish water under pressure for sluicing into place the material for their new dam.

This pump is a 10-inch, class "F," two-stage centrifugal, with bronze inpellers and renewable bronze diffusion vanes. It has a normal capacity of 1833 imperial gallons per minute when operating at 1160 r.p.m. against a total head of 355 feet or an equivalent pressure of 154 lbs. per square inch. It is mounted on a common sub-base with a 300 h.p. type "B," Fairbanks-Morse squirrel cage, induction motor, 2200 volts, 60-cycle, 3-phase, 1160 r.p.m. at full load, being direct connected thereto by means of a flexible leather link coupling

The motor possesses a feature in rotor construction that is unique. The end rings are welded on to the rotor bars by a new process, making a perfect joint, free from the troubles common to the purely mechanical or riveted joint, such as oxidation, working loose, and solder-throwing. This improvement marks a long step forward in the elimination of rotor trouble.

Our Vancouver Branch supplied and assembled this complete pumping unit. We are in a position to quote on the necessary equipment for any pumping requirements on receipt of specifications.

A NEW MANUFACTURING COMPANY.

A new company, Forter and Kilpatrick, Limited, has been formed for the purpose of taking over for the Province of Ontario, the patent rights and the sole right to manufacture sewer pipe with the Thomas Glazed Cement Sewer Pipe Machine. The company has also the sole rights to manufacture and deal in "Trojan" partitions and ceilings, stonewood plastic flooring, "Sorce" asphalt and waterproofing. It is understood that a number of large contracts have already been secured throughout Canada. The headquarters of the company at present are with the Prudential Trust Company, Ltd., Home Bank Building, 8 King Street West, Toronto.

◆

DIMINISHING RAILWAY RETURNS.

Confidence in the ability of a railway company properly to continue its operations and adequately to maintain and extend its facilities depends in greatest measure upon its net operating revenue. This is what is left of the receipts from traffic constituting the total operating revenue, after the operating expenses have been met. As the mileage of the railways tends to increase year by year, an accurate measure is obtained of the operating revenues, operating expenses, and net operating revenue by ascertaining what they have amounted to for each mile. It may be, for example, as was the case in March, that while in the aggregate net operating revenue has increased, it has decreased when measured per mile of line.

Monthly summaries of the revenues and expenses of the steam railways of the United States have been compiled by the Bureau of Railway Economics from the reports filed month by month by the railways with the Interstate Commerce Commission, for the twenty-two months from July, 1910, to April, 1912, the latest month for which returns are available. Net operating revenue per mile of line for the railways as a whole in comparison with the corresponding months of the previous year decreased in eighteen of these months, and increased in but four. The decrease per mile of line per month was as great in amount as $53, and as great in ratio as 15 per cent. The greatest increase for any one of the four months showing increases was $31, or 14.1 per cent. This was in February, 1912, and was exceptional as this month contained one more day than February, 1911. The highest average net operating revenue per mile of line for any one month of this period was $409, the lowest $203.

Seven of the ten months from July, 1911, to April, 1912, show decreases in net operating revenue per mile of line as compared with the corresponding months of the fiscal year ending June 30, 1911; and eleven of the months of the fiscal year which ended June 30, 1911, showed decreases in comparison with the respective corresponding months of the fiscal year ending June 30, 1911. It it therefore evident that the trend of railway net revenue has been downward for the [illegible].

The summary for April, 1912, shows that net operating [illegible] 945, averaged $8.57 for each mile of line for each day in [illegible] year. This is the gross income per mile of line per day before anything has been taken out for taxes, rentals, interest on bonds, appropriations for betterments or dividends. Taxes for April [illegible] per cent.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

16921—June 27—Authorizing G.B. & S. Ry. (C.P.R.) and G.T.R. to operate trains over crossing at mileage 50.5 from Victoria Harbor, account interlocker completed; and G.B. & S. Ry. (C.P.R.) and James Bay Ry. (C.N.R.) at Brechin, Ont., account interlocker completed.

16922—June 28—Temporarily approving G.T.P., C.R.C. No. 10, Standard Freight Mileage Tariff to supersede C.R.C. No. 7.

16923—July 2—Authorizing Algoma Central and H.B. Ry. to open for carriage of traffic its line between mileage 85 and mileage 93, north of Sault Ste. Marie.

16924—July 2—Authorizing Canadian Copper Co. and Algoma Eastern Ry. to open trains over crossing in Twp. of McKim, account half-interlocker completed.

16925—July 2—Authorizing C.N.P. Ry. and C.P.R. to operate trains over crossing on C.P.R. Mission Branch, account interlocker completed, B.C.

16926—July 2—Approving location of C.N.R. through Twps. 24-22, Rge. 1, west 5 M., and Rge. 29, west 4 M., Alta., M. 0.0 to 13.21.

16927—June 29—Authorizing C.L.O. & W. Ry. (C.P.R.) to cross 4 highways, and to divert highways between mileage 165.46 and 165.96, Ontario.

16928—July 2—Authorizing C.P.R. to construct additional track across Queen Street, Port Moody, British Columbia.

16929—July 2—Authorizing C.P.R. to construct its Moose Jaw Southwesterly Branch across highway at mileage 29.75.

16930—June 29—Authorizing G.T.P. Ry. to construct spur to Union Stock Yards, St. Boniface, Man. Crossing of C.N.R. to be protected by interlocker.

16931—July 5—Extending until Aug. 1, 1912, time for putting into effect Order 16479, May 10, 1912.

16932—July 4—Authorizing C.P.R. to open for carriage of traffic its Moose Jaw South Westerly Branch from mileage 27.4 to 35; speed limit of 15 miles.

16933-34-35—June 29—Authorizing Edmonton, Dunvegan and B.C. Ry. to cross 5 highways in Alberta; and approving its revised location through Twp. 55, Range 25, W. 4 M., and to cross highway between Secs. 33 and 34, Twp. 55, Range 26, W. 4 M.

16936—June 28—Directing G.T.R. to construct improved type of electric bell at two crossings in village of Corinth, Ont., 20 per cent. from Rly. Grade Crossing Fund.

16937—June 29—Approving location Kettle Valley Ry. from Penticton to Coldwater, B.C. (Section A).

16938—July 6—Approving location Alberta Interurban Ry. through Sec. 13, Twp. 24, R. 1, west 5 M., mileage 1.25 to 2.28, in city of Calgary, Alta.

16939—July 4—Directing that Vancouver, Fraser Valley & Southern Ry. be subject to penalty of $25 a day after 10th July, 1912, it shall be in default of requirements of Order 16225, April 3rd, 1912, re filing tariffs.

16940—June 29—16941—July 2—Authorizing C.N.O. Ry. to cross two public roads in Twp. of Westmeath, County of Renfrew, Ontario.

16942—June 29—Amending Order [illegible], May 31, 1912, by adding words "and maintain" after word "construct," in 2nd line of operative part of the Order.

16943—June 27—Approving changes in G.T.R. bridges in Township of Tay, to carry railway across public road.

16944-45—July [illegible]—Authorizing G.T.R. to construct spurs to serve Meaford Brick Co., Con. 1, Twp. of St. Vincent, County Grey, Ont., and Alabastine Hardmortar Co., Ltd., Toronto.

16946-47—July [illegible]—Approving G.T.R. plans for bridges 183 and 77, on its Northern and Ottawa Divisions, and [illegible] bridges on its 12th and 15th Districts.

[illegible]—June 29—Authorizing Campbellford, Lake Ont., & Western Ry. to [illegible] railway in the village of Newcastle, and Twp. of Hope, County of Durham, Ont.

[illegible]—July [illegible]—Authorizing C.P.R. to reconstruct two bridges on its Windsor and Ontario S. Divisions, and construct two bridges on its Campbellford, Lake Ont., & Western Subdivision, mileage 180.57 and 0.91, Ont.

[illegible]—Extending until 31st day of July, 1912, time for completion of electric bells by C.P.R. as required by [illegible] C.P.R., [illegible] at Wolverton, Ont., and extending [illegible] time for completion by C.P.R. of [illegible]

[illegible]—May [illegible]—Relieving C.P.R. from erecting and maintaining fences [illegible]

[illegible]—July [illegible]—Authorizing C.P.R. to construct spur for Canada Cement Co., Ltd., under [illegible] Calgary, [illegible], Alta.; [illegible] County of L'Assomption, Que., [illegible] Flour Mills Co., [illegible] Montreal, Que.

[illegible]—July [illegible]—Authorizing C.P.R. to expropriate land for Windsor [illegible]

[illegible]—July [illegible]—Directing G.T.R. to [illegible] at Windsor, Ont., [illegible] County of Essex, Ontario.

[illegible]—June [illegible]—Relieving G.T.R. from [illegible] protecting crossing [illegible] Man.

[illegible]—July [illegible]—Extending [illegible] time for completion of [illegible]

[illegible]—July [illegible]—Relieving C.P.R. from further protecting crossing [illegible]

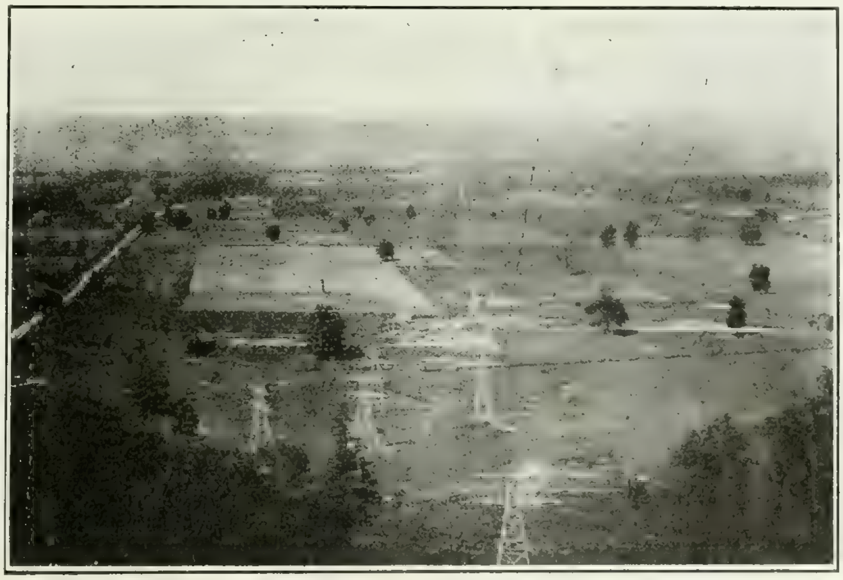
An Engineering Weekly

THE HIGH TENSION TRANSMISSION SYSTEM OF THE HYDRO-ELECTRIC POWER COMMISSION OF ONTARIO.

Description of the System.

The high-tension steel tower transmission system described herein is, perhaps, the most prominent example of high-tension transmission in the world. The system operates at a potential of 110,000 volts, and was designed and constructed by the Hydro-Electric Power Commission of Ontario, a government corporation appointed by the Provincial Legislature to provide for the development, generation and distribution of hydro-electric energy at cost to the various municipalities of the province.

Ultimately, the commission plans to extend its system over the entire province; particular attention being given the central and northern districts, where the available water powers have an aggregate horse-power of more than twice that of the Niagara district, although the latter district is the only one that has been developed to date by the commission.



General View of High Tension Transmission lines in Dundas Valley.

System.—There are 281 miles of steel tower line sectionalized as shown in Table I., and twelve transforming stations. The general map shows the extent of the system.

It will be noticed that while two circuits have been erected in Sections A and B, only one circuit has been erected throughout the rest of the system. The reason for this is apparent upon examination of the accompanying map. All the stations beyond Dundas, with the exception of Toronto and St. Thomas, are on a loop circuit and as a result may be served from Dundas in either direction around the loop. Under normal operating conditions, the direction of current flow is from Dundas to London on the south side and from Dundas to St. Marys on the north side of the loop, the line between St. Marys and London being held in reserve.

The main step-up transformer station of the system is located at Niagara Falls, Ontario, where the energy, purchased from the Ontario Power Company and supplied at 12,000 volts, 25 cycles through a 2,200-foot conduit line, is stepped-up to 110,000 volts for delivery to the three-phase high-tension lines. The present installed transformer capacity at this station is 27,000 kw.

The transmission voltage is later stepped-down to 13,200 and 6,600 volts for local and low-tension distribution at the following sub-stations, the installed transformer capacity being as follows: Dundas, 2,250 kw.; Toronto, 7,500 kw.; London, 3,750 kw.; Guelph, 2,250 kw.; Preston, 2,250 kw.; Berlin, 2,250 kw.; Stratford, 2,250 kw.; St. Marys, 2,250 kw.; Woodstock, 2,250 kw.; St. Thomas, 2,250 kw.; Port Credit, 3,750 kw.

Construction of Line.

Surveys.—The territory embraced by the high-tension transmission system was first covered by reconnaissance to determine the most feasible route for the line. The preliminary examination was performed with the primary intention, wherever possible, of adopting a route parallel to travelled roads, in order to reduce the transportation, maintenance and patrol costs to a minimum. In selecting the route care was also taken to avoid any sections of country subject to electric storms, and some projected and otherwise favorable routes were abandoned as a result of information supplied by telephone and telegraph companies already operating in these vicinities.

After the route has been selected an instrument survey was made. No profiles were, however, necessary; for the towers were located and staked in the field, and the locations

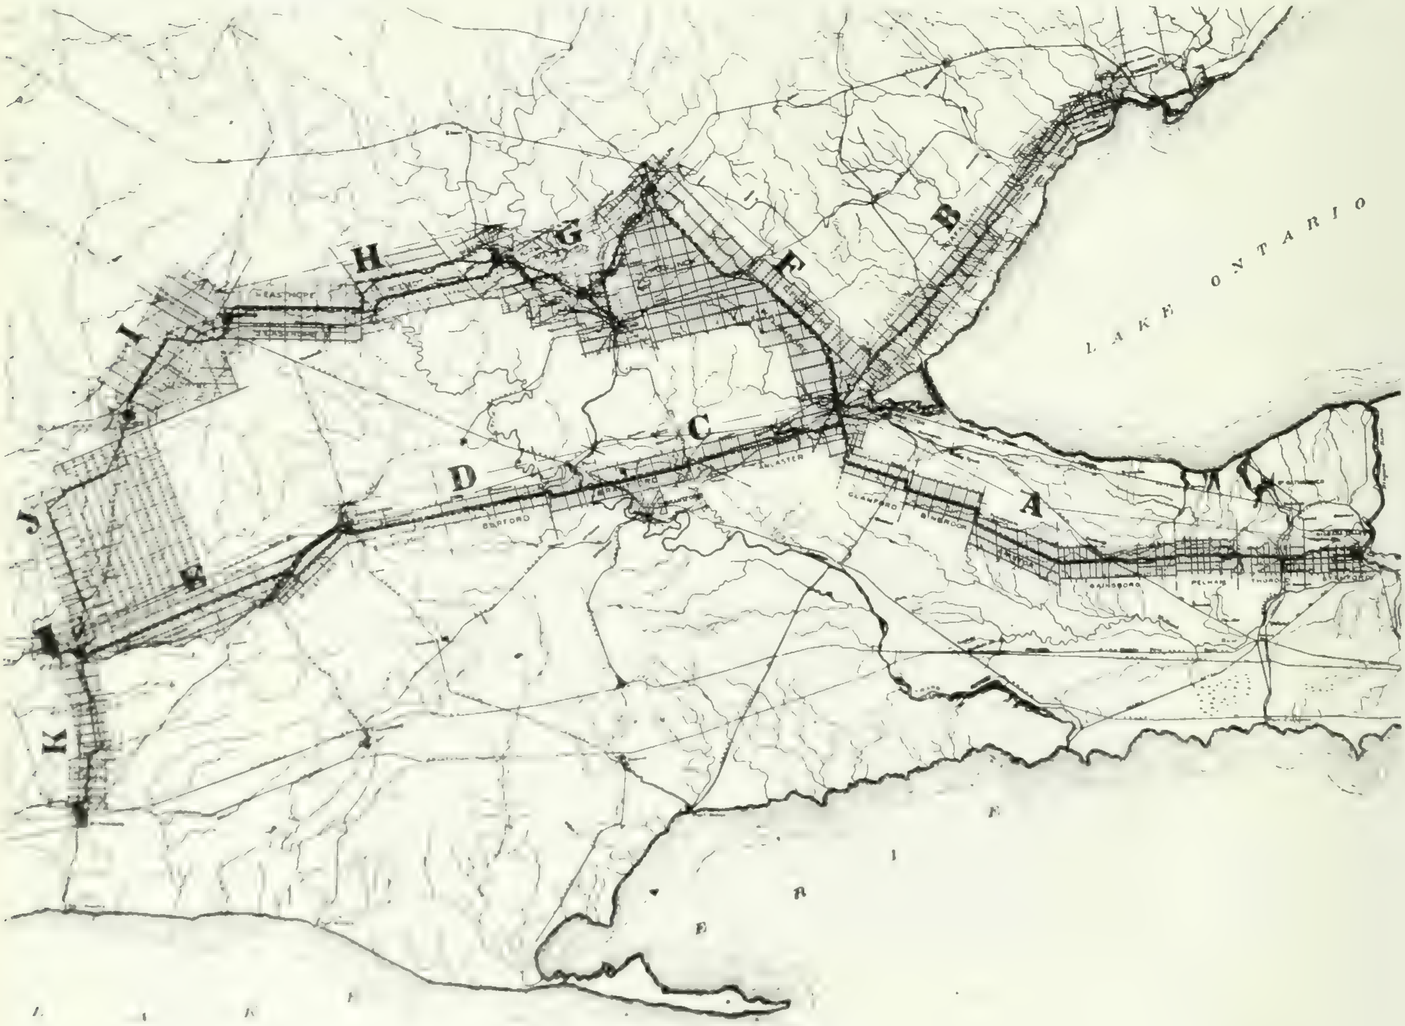
Section J, St. Marys-London	23.6	Single-circuit	1
Section K, London-St. Thomas	13.4	Double-circuit	1



Map of Transmission System.

thus established were plotted on the plans. These plans were employed by the commission while purchasing right-of-way and later by the contractor to locate the towers. The tower locations were staked by small transit parties sent out the line ahead of the construction gangs. They first set a hub marking the centre of the tower base and then two other hubs along the tower tangent marking the centre of two opposite sides of the square tower base. A reference stake was then driven upon which was marked the number, type and location of the tower.

Right-of-Way.—The transmission line right-of-way was acquired through easements, which give the commission the privilege to enter upon property and to construct, maintain, operate, repair and patrol their transmission line for a period of thirty years. Every property owner along the route signed an agreement whereby, for an amount mentioned therein, these rights and privileges were conferred upon the commission. The remuneration included compensation for all trees, houses, barns or other obstructions which were permanently removed from the right-of-way. Patrol rights were purchased only on cross-country sections, since they were not needed where the line parallels the highways. The patrol paths are four feet wide and are provided with light steel gates at intersecting fences.

The commission has the right to renew these agreements at their expiration for an amount equivalent to the original compensation or one settled by mutual agreement or arbitration. This method of acquiring right-of-way dispensed with the necessity for fencing the land beneath the line and also permits of its cultivation.

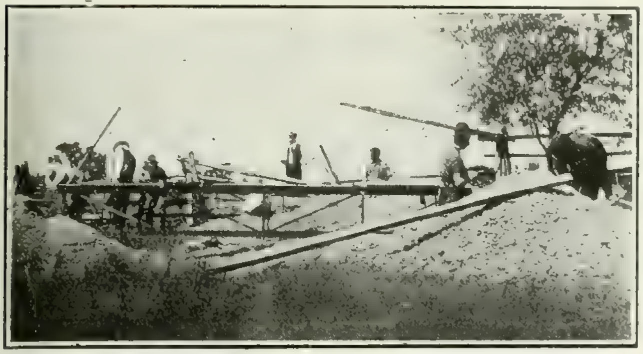


Fig. 1.—Setting of Tower Footing, Showing Templet.

Footings.—The standard tower footings consist of rivetted-steel grillages 28 inches square, embedded in the soil at a depth of about seven feet and horizontally bolted to an eight-foot leg angle protruding from 12 to 15 inches above the natural surface of the ground. Similar footings are employed for long span and corner towers, but the steel is heavier and the grillages are 42 inches square.

The grillages are shop-rivetted and the leg angles bolted to them in the field. The footing steel was not galvanized, receiving instead two coats of special protective paint. Approximately 1,000 tons of footing steel were utilized in the construction of the line.

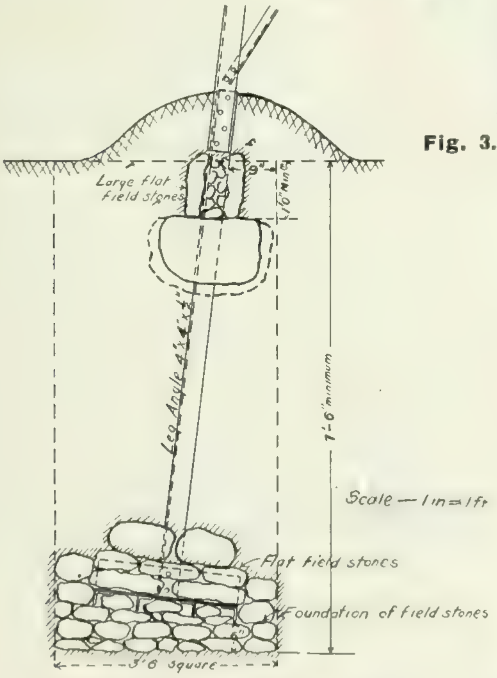

Fig. 2.—Setting of Standard Tower Footing in Earth.

The four footing pits for each tower were blocked out by two men with a light wooden templet from the three hubs previously located by the transit party and a gang of laborers excavated the pits to a minimum depth of 7 feet 6 inches.

Closely following came a gang of twelve men and a foreman. They carried a steel templet with corner posts having the same slope as the leg angles of the towers. This gang placed the footings in the pits, bolted the leg angles securely to the corner posts of the templet, (Fig. 1) lined the templet in with the three hubs set by the locating party, levelled the four sides with a spirit-level, placed the field stones, back-filled and watered the pits and thoroughly tamped the replaced earth with iron tamping bars, as shown in Fig. 2. This gang, under favorable working conditions, could prepare an average of five sets of footings a day. The labor cost on the standard footings in moist or dry soil ranged from $15 to $25 a set. This included the cost of excavation, setting and back-filling.

Fig. 3.—Tower Footing Where Rock Occurs Less Than 6 Ft. Below Earth Line.

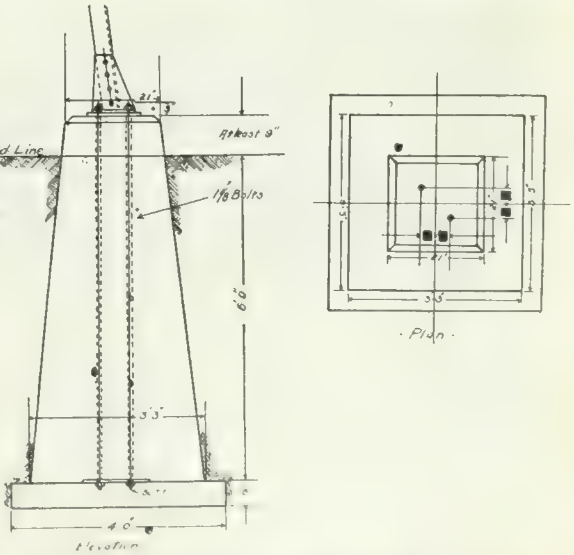

Fig. 4—Concrete Footings for Heavy Anchor Tower.

In locations where quicksand, rock or very wet soil was encountered special construction was necessary and another gang was employed for this purpose. In swamp, where good bottom was within reach, the pits were shored and the soft material removed. The shoring was left in place and the pits refilled to the proper depth with good material. The footing was then set in the usual way. In permanently wet clay or clay loam auxiliary grillages were placed above and below the ordinary steel grillages to further distribute the bearing pressure and increase the upheaval resistance. This auxiliary grillage consisted of two cross-laid spiked layers of four-inch planks five feet in length placed below, and four cross-laid spiked layers of three-inch planks placed above the steel grillages. Where rock was encountered less than six feet from the surface a fox-tailed anchor bolt with pier construction was used (illustrated in Fig. 3). Connections between the lower legs and the anchor bolts were made by means of heavy steel shoes. Where corner towers were placed on long spans, large angles or in poor locations the concrete footings shown in Fig. 4 were used. The cost of this footing, including material and labor on excavation and forms was from $50 to $190, the higher cost occurring in [illegible] [illegible] [illegible] [illegible] [illegible]. The standard steel grillage and leg angles weighed [illegible] pounds per tower, while the [illegible] [illegible] footings weighed [illegible] pounds.

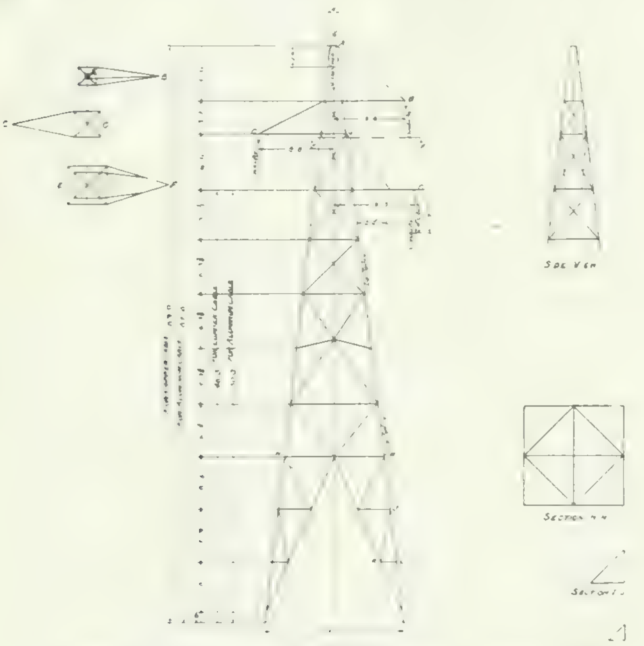

Fig. 5 A.—Standard Single-Circuit Towers.

Fig. 6.—Erecting Tower With Gin Poles.

Towers.—The towers are constructed of open-hearth [illegible] steel and were built from designs prepared by the engineers of the Hydro-Electric Power Commission in competition with designs submitted by the contractors. Sample towers were built from both designs, and [illegible] tests to the [illegible] of [illegible] [illegible] proved that the tower built from the Commission's design was the strongest tower of the two (Fig. 8). This tower withstood, without appreciable injury, a horizontal stress of 20,000 pounds at the centre of the lower cross-arm, and finally failed at 20,950 pounds.

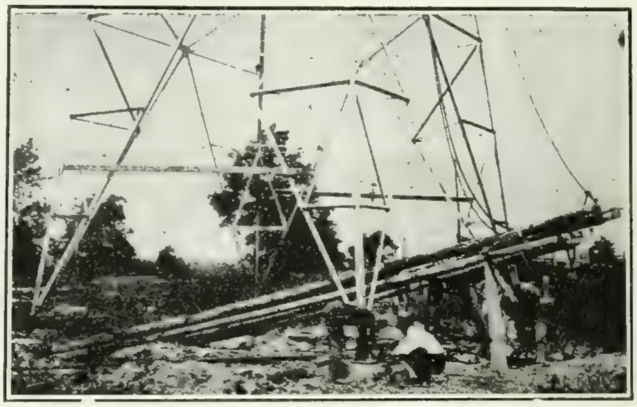

Fig. 7.—Erecting Tower With Shear Legs.

The average cable span length on tangents for level country is 550 feet. This is varied elsewhere to suit topographical conditions. Approach spans to angles in the centre line vary from 400 feet on angles up to 8 degrees, to 100 feet on angles of 45 degrees, the maximum angle turned on one tower. The towers were delivered "knocked down"

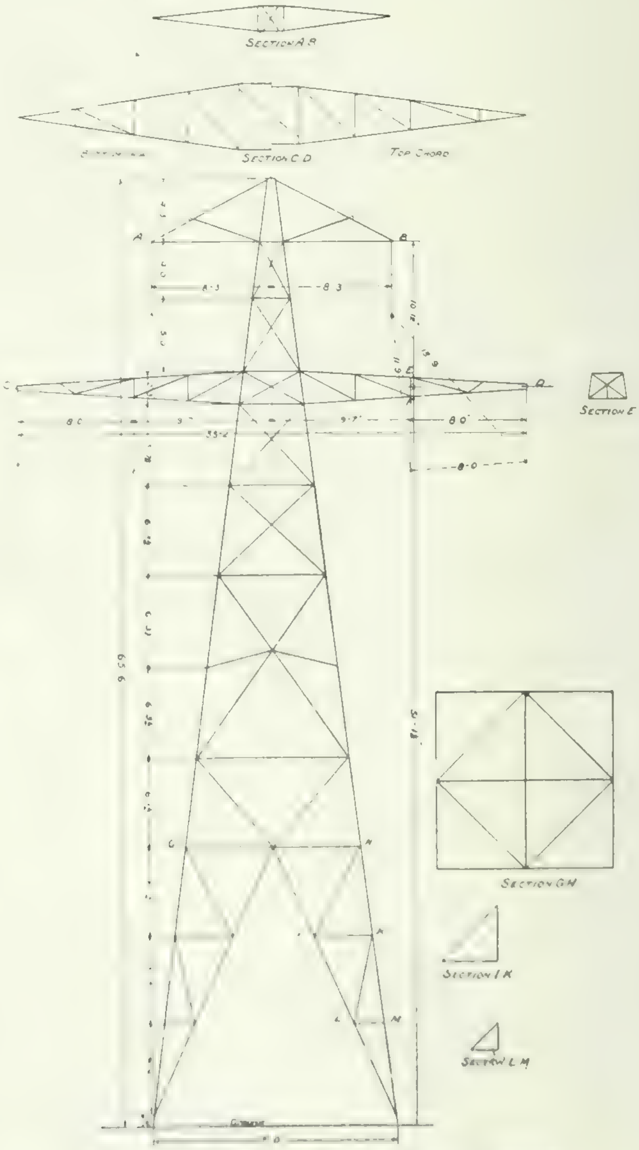

Fig. 5 B.—Standard Double-Circuit Towers.

in bundles to various railway sidings and transported by team to the line. All connections were made by means of galvanized bolts, the required number being delivered with each tower.

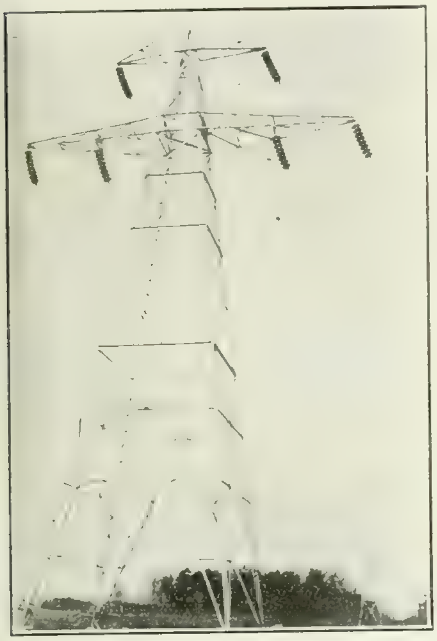

Fig. 8.—Standard Double-Circuit Line Tower.

An assembling gang, usually consisting of eighteen men including a foreman and sub-foreman, followed the footing gang. Two men from this assembling gang went ahead to break out the bundles and lay out the towers on the ground. The main gang assembled the body of the tower, while the cross-arms were assembled by a gang which followed consisting of three men and a sub-foreman. All bolts were drawn tight and the projecting threads burred with a hammer or centre-punch. This assembling gang working winter and summer could assemble an average of three and one-half towers a working day. Under favorable summer conditions from five to six towers a day were assembled. The average winter and summer labor cost for assembling a double-circuit tower was $10; the maximum cost in winter with heavy snow was $24, and in summer with good weather conditions $6.25 a tower. The single-circuit towers were assembled in summer at an average cost of $7.35 a tower.

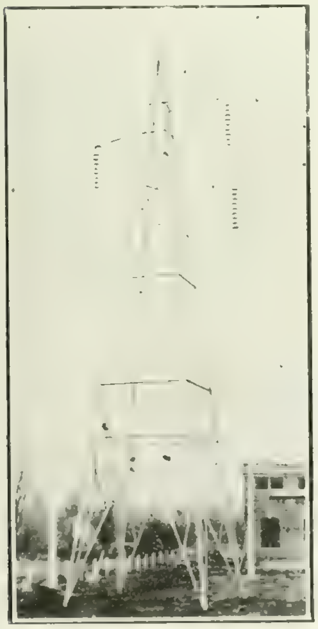

Fig. 9.—Standard Single-Circuit Tower.

The erection gang, consisting of five or six men with a foreman and team, followed the assembling gang. Gin-poles, A-frames and shear-legs were variously employed for the erection of the towers, the shear-leg method, however, was found to be the most satisfactory. (Figs. 6 and 7). The method of erection was as follows: Temporary stiffening struts were bolted to the tower legs; the shear-legs were placed in a vertical position about the centre of the tower base and the toes securely snubbed; a heavy line leading from a set of double blocks was then carried over the shear-legs and attached to the tower just below the lower arm; the blocks were snubbed to "dead-men" and the tower drawn into a vertical position by a team, after which stiffening struts were removed and the tower legs bolted to the footing angles. The average rate of erection under various conditions was about four towers a working day. During the summer and in good country eight towers a day could be erected in straight runs by the erection gang. The average labor cost for erecting double-circuit towers was $4.75 a tower, the minimum cost $2.45. Single-circuit towers were erected at an average cost of $3.50 a tower. All work on single-circuit towers was done in the summer and early autumn.

Fig. 10.—Special Tower, Toronto Entrance.

The double-circuit towers, of the general design shown in Fig. 8, are classified as "standard towers," "line anchor towers," and "corner and long-span towers." General specifications are given in Table II.

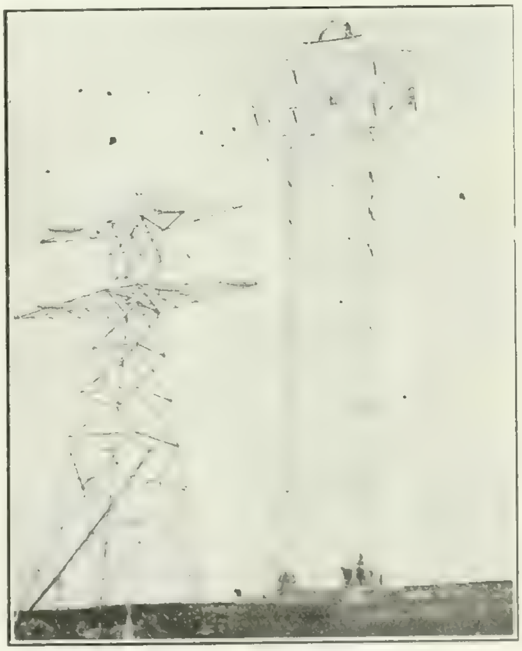

Fig. 11.—Special Tower at Welland Crossing.

In addition to the standards mentioned on the following page, other special towers required were: Twenty-eight double-circuit towers designed to support the lower conductors 50 feet, 55 feet and 70 feet above ground, and employed for crossing high-tension transmission lines; forty double-circuit towers (Fig. 10) designed to give 70 feet conductor clearance above ground, employed within the corporate limits of Toronto; two double-circuit towers giving 150 feet navigable clearance over the Welland Canal, and thirty-six horn-gap towers 19 feet in height at station entrances

The towers used in crossing the Welland Canal (Fig. 11) weighed 25 tons each and were erected on specially designed reinforced concrete footings. The complete system required in all 3,040 towers, and the total weight of galvanized material ordered was 6,200 tons.

SOME NOTES ON BAND CONVEYORS.

By F. Tissington.

(SECOND ARTICLE.)

The following eleven diagrams show different arrangements for these band conveyors.

Fig. 1 indicates a plain horizontal conveyor having the tension end (screw type) arranged at the loading end of the conveyor and the driving gear at the other.

Fig. 2 is a similar arrangement but with two methods indicated for a weighted tension.

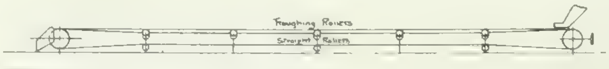

Fig 1

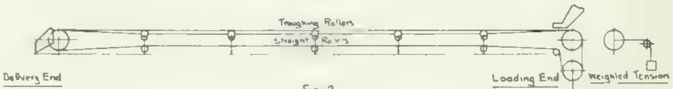

Fig 2

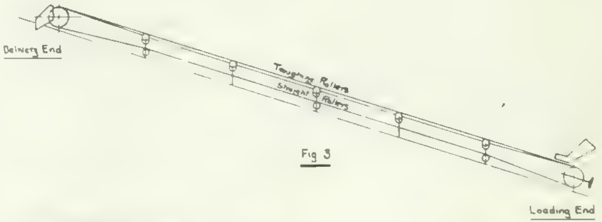

Fig 3

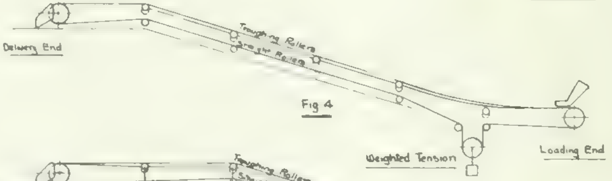

Fig 4

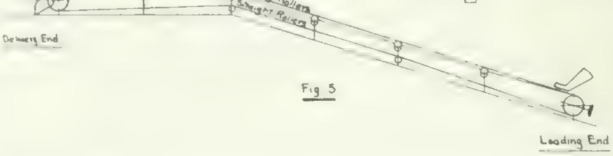

Fig 5

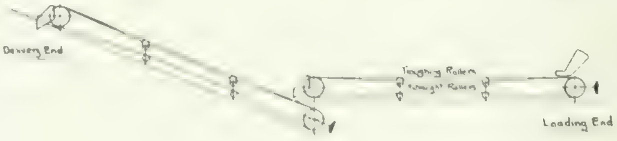

Fig 6

Fig. 3 is an inclined conveyor with driving and tension ends similar to Fig. 1.

Fig. 4 is another type of a combined horizontal and inclined conveyor with one or more loading points and this shows a weighted tension arranged at an intermediate point between the two ends. The pulley at the loading end being mounted in fixed bearings.

Fig. 5 is type of a partly inclined and part horizontal conveyor with a screw tension.

Fig. 6 shows two conveyors, one horizontal and delivering on to the second, which is inclined.

Fig. 7 indicates how the driving gear may be arranged if required to be placed other than at the two ends.

Fig. 8.—This arrangement is a modification of Fig. 6, and, if required, may be driven from one of the pulleys in the centre of the belt.

Fig. 9. This shows an ordinary horizontal conveyor fitted with a throw-off carriage or tripper. The latter may be either stationary or arranged to travel along the length of the belt.

Fig. 10. This is a similar arrangement to the previous one, but indicates that two trippers may be used on the same belt, and if this is done one of them usually has a special spout to return material carried to the band when required.

Fig. 11 shows a reversing conveyor which may be loaded from each end alternately and by means of the tripper the material may be delivered at any point along its length. Other combinations may be arranged to suit any particular scheme, and these diagrams are simply given to indicate a few of the various arrangements that may be made.

Driving Gear.—Usually the first set of gear is supplied with the conveyor, including countershaft and bearings, and the latter, together with the bearings for the drum shaft, are mounted on a combined sole plate, either of cast iron or a short length of I-beam. The terminal pulleys should all be about one inch wider than the width of the band for widths up to about eighteen inches. Above this the extra width should be at least two inches more. This is done in order to prevent the edge of the belt being cut through or getting ragged at the edges, which would probably happen if the belt overlapped the pulley due to the tendency all belts have to travel sideways slightly.

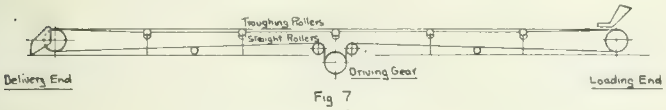

Fig 7

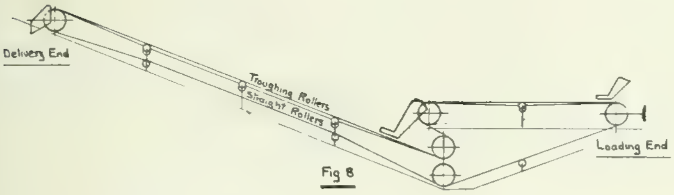

Fig 8

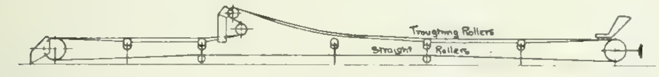

Fig 9

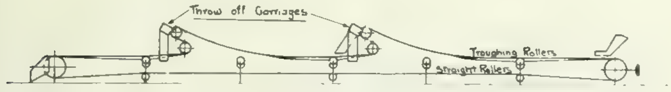

Fig 10

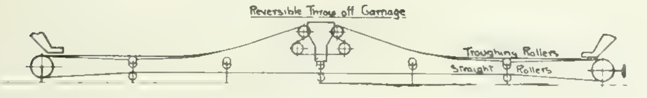

Fig 11

The pulleys may be made of either cast, wrought iron, steel or wood. Cast iron pulleys are very seldom used now on account of their weight and greater liability to damage. The wrought iron or steel rim pulley, with wrought iron round spokes rivetted to the rim, and with a cast iron boss, either solid or split, is the general practice. These give very good results, are cheap, and there is very little danger of breakage, also the weight is comparatively small. For the wider belts it is necessary to introduce double arm pulleys or otherwise put two or three single arm pulleys side by side on the same shaft to make up the width. If, however, this latter is done the pulleys should be faced up in the lathe mounted on the shaft in position in order to produce a true and even surface without ridges.

All wood pulleys are now made in large quantities, are very serviceable, and, further, have the advantage of an increased coefficient of friction, which gives them a slight advantage, but in the writer's opinion this is more than counteracted by the shorter life they possess, especially if used in a damp situation or a moist climate.

Sometimes the pulleys are covered with a rubber face, in order to gain an increase in the coefficient of friction and thereby add to the driving power, and, roughly, it may be said that this gives something like an increase of about 7 per cent. to 10 per cent. over and above the power obtained by the use of a plain-faced pulley.

Like the use of the wood pulley, this practice also has an objection, namely, that if any gritty material is being carried it is likely to get on the underside of the belt, and, sticking in the rubber facing of the pulley, cause rapid wear to take place.

The bearings for the drum shaft can be of cast iron fitted with adjustable gun metal bearings, and provided with large-sized grease lubricator.

Some engineers specify self-oiling bearings of the ring type, but this seems quite a needless expense, for the drum shaft at any rate. These self-oiling bearings are, however, very desirable when the revolutions of the shaft are rather high, which may be the case with the countershaft very often.

Tension Gear.—If this is of the adjustable screw type it is preferable to arrange the screws in tension if possible, and perhaps the best type is the one with the screw fixed in relation to the frame, but free to revolve in bearings and having a nut mounted on the screw, which is located in the pedestals, or filbows carrying the drum shaft. Then the screw is fitted with a small hand-wheel which, on being turned, traverses the bearings along the screw either backward or forward. Occasionally the two tension gears are coupled together with gearing, so that there is no likelihood of one side traveling in advance of the other and so causing the belt to run out of true. This, however, is purely a requirement for which there should be little necessity if the attendant is at all careful.

It was stated in the previous article that there was certainly a great danger of overstressing the fabric with this type of tension gear, and that the weighted tension was likely to give better results. On account of the extra cost, however, these seem to be avoided in most cases, particularly for the narrower and shorter belts.

This other type of tension gear consists of two fixed pulleys (one of which may be the end drum) and one other pulley mounted on a shaft free to travel up and down in guides and loaded with sufficient weight to produce the necessary tension in the belt for driving.

A modification of this can be arranged with one of the drum shafts free to move horizontally to which is attached a wire rope which passes over a pulley and to the other end of the rope are attached weights of sufficient capacity as before. The diameter of the terminal pulleys should not be less than the following:

3-ply belts from 18 to 24 diam., according to width of belt
4 " " 24 to 32 " " " "
5 " " 30 to 36 " " " "
6 " " 36 to 42 " " " "
7 8 " " 42 to 48 " " " "

TABLE I.

CAPACITIES OF TROUGHED BELT CONVEYORS

Material Weighing 125 Pounds per Cubic Foot

Width of Conveyor Belt Inches	Speed, 200 Feet Per Minute.		Speed, 400 Feet per Minute		Speed, 600 Feet per Minute

34	8	280	5	568	2	1040
36	9	360	6	680	2	1200

Grain Weighing 60 Pounds per Bushel

Width of Conveyor Belt, inches	16	18	20	22	24	26
[illegible]	2500	3250	4000	4750	5500	6250
[illegible]	3000	4800	6000	7000	8500	9500
[illegible]	28	30	32	34	36	40
[illegible]	7000	7750	8500	9250	10000	13000
[illegible]	10500	11500	12500	14000	15000	19500

Gripping pulleys should never be less than 12 inches diameter, and should exceed the width of the belt by the same amount specified for end pulleys.

Bands.—These may vary from about 10 to 42 inches in width and the general width per ply will average about five inches, although, of course, heavier bands may be required for some conveyors in order to give the necessary strength to transmit the horse-power required. The average weight of rubber covered conveyor belts is as follows:

3-ply .15 lbs. per in. of width
4-ply .20 lbs. per in. of width
5-ply .25 lbs. per in. of width
6-ply .30 lbs. per in. of width
7-ply .35 lbs. per in. of width
8-ply .40 lbs. per in. of width

The tensile strength of rubber belts varies from about 35 lbs. to 60 lbs. per inch width per ply. But for usual practice not more than about 25 lbs. per inch width per ply should be utilized; this being calculated from the maximum tension on the tight side of the belt.

Makers of solid woven cotton belting give the following figures for the average tensile strength and weight:

	Average Tensile Strength Per inch width	Average Weight per inch width 100 ft. length.
Single belt ¼ in. thick......	1,300 lbs.	10 lbs.
Extra stout ⅜–7/16 in. thick..	2,300 lbs.	15 lbs.
Triple ½–9/16 in. thick......	3,000 lbs.	20 lbs.

It would seem that comparing these figures everything was in favor of the cotton belt, but from what has been said before it is evident that the life of the cotton belt is very much shorter, and owing to this, the apparent advantage is lost.

The length of these conveyors sometimes run over 1,000 feet, but usually they do not exceed 500 to 700 feet, and if a longer length is desired it is generally better and cheaper in the long run to split it up into two or more sections driving each conveyor separately.

Endless belts are sometimes made for the shorter conveyors, but in the writer's opinion there is not much to be gained by their use, as they make erection work very awkward in most instances, and further, there are plenty of good fasteners of one sort or another on the market, thus doing away with the necessity for the endless belt.

The ideal fastener is one that develops the maximum amount of strength without forming projections or producing flat surfaces in the bands when passing round the pulleys, as the amount of lost arc of contact reduces the driving power of the belt when it is in this position.

The troughing of the belt should not exceed about 25 degrees with the horizontal, although rollers have been made with inclination as high as 35 and 40 degrees, but unless the belts are very flexible no contact will be made with the middle horizontal rollers, and greater wear will result at the edges of the belt.

Some makers advocate the flat band pure and simple, but this is likely to lead to the use of wider bands to get the required capacity, or else a greater danger of spilling.

The maximum amount of slope or inclination that should be given to a plain belt carrying coal, ore, stone, sand and similar material is about 20 degrees, although 25 degrees may be used in special cases if the material is not of a nature that will slip or roll easily. The former is the safer figure, as an increased inclination is likely to occur owing to the belt sagging between the supporting rollers or idlers due to the weight of material carried. If, however, throw-off carriers or trippers are used the maximum inclination should be reduced to 10 or 15 degrees on the portion of the belt leading up to the top pulley on the carriage, and this may be regulated by placing a set of idle rollers on the back end of the carriage.

The speed of the belt depends entirely on the nature and size of the smallest pieces to be carried. Generally, however, the speeds should be kept as low as possible, consistent with other features, as with high speeds there is a danger of spilling and slipping at the loading end, particularly if the belt at this point is inclined. Further, beyond a certain point it is impossible to obtain a greater capacity in any reasonable ratio of the speed as the material cannot be fed quickly enough to the band and, therefore, the stream thins out. If there is any quantity of fine dust in the material it will be found that about 200 feet per minute is the limit, because, with higher speeds the fine material has a tendency to leave the belt and float in the atmosphere, due to the resistance of the air. If, however, ore, stone, coal or other material in lumps is being handled, 600 feet per minute may be safely used without any bad results.

Large lumps cannot be satisfactorily carried on narrow belts without the danger of a good percentage dropping off, and the figures given in Table I. show the practice adopted by the Dodge Manufacturing Company in this respect.

It will also be noticed that capacities for the different belts are given for two different classes of materials in addition to grain, one of the substances weighing 125 lbs. per cubic foot and the other for 100 lbs. per cubic foot, and that three different sets of figures are given corresponding to 200, 400 and 600 feet per minute belt speed.

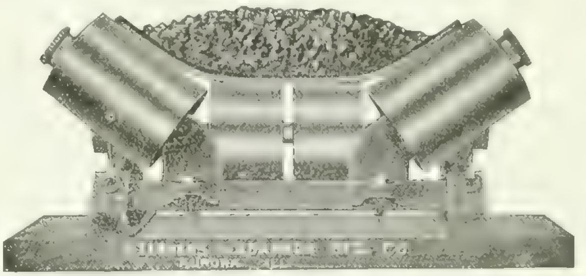

Fig. 12.

It may be said that the most economic designing will be obtained by increasing the width of the belt and keeping the speed at a moderate amount, because it is impossible to load a belt the full width across, and as the amount of clear space will not vary much, whatever the width of the belt, it will be seen that the percentage of lost capacity on this account will be much greater on a narrow than on a wide belt.

Idler Rollers.—The spacing of these should be to a large extent regulated by the material to be conveyed. If the latter is very heavy then the rollers should be put fairly closely together. For most work, however, about four to five feet apart on the carrying side will be suitable for belts up to about thirty inches wide, beyond this they should be about three feet six to four feet. The return strand should be supported about every eight or ten feet, or generally twice the distance of the top rollers.

Both top and bottom rollers should be long enough to leave about one inch margin on each side of the belt for a similar reason to that stated for the end pulleys.

If the top rollers are of the troughing type the design should be carefully laid out to prevent the pinching of the band between the sectional rollers forming a set. That is, no large opening should be left between each section so that the belt can be forced down in between by the weight of the material on top.

The writer has heard of a case where a band was practically cut into two parts longitudinally owing to a circumstance of this sort happening, thus causing a severe loss.

Rough castings for rollers should be avoided. These should either be turned or the rollers made from cold drawn tube and fitted with bearings to revolve on. These latter make a first-class job, and if the parts are made in automatic machines they can be produced very cheaply.

Each set of rollers is mounted on a cross member or stretcher either of wood or steel, and these are generally provided by the contractor, with the rollers all fitted up in position ready for the stretcher complete to be erected in its correct place in the structure. The angle of inclination for troughing rollers has already been mentioned in connection with the band, but should not be confused with the inclination of the whole conveyor with the horizontal. The diameter of the idler rollers is generally from four to six inches, according to the speed of the belt.

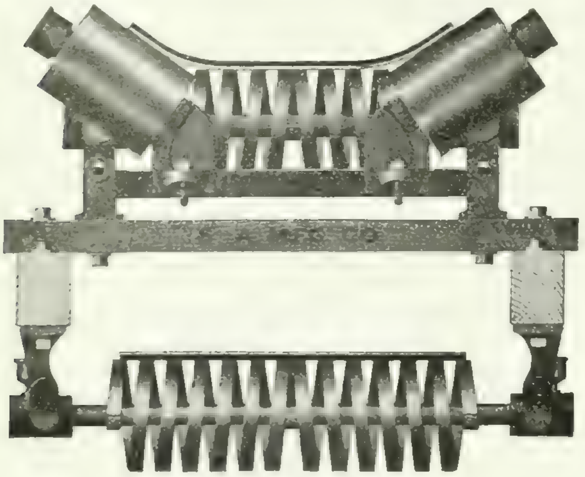

Fig. 13.

Lubrication of these rollers is quite an important item, as the revolutions will vary anything from two to four hundred per minute. A common way to arrange for this is to mount the rollers on a hollow spindle and drill these tubes at right angles at several points along the bearing of the rollers. The ends of the tubes are then closed with grease lubricators of the screw or spring type, which force the grease down the tube and through the holes into the bearings. This leaves the tubes full of grease all the time and practically makes the bearings dust-proof and prevents overheating, as a small percentage rise in temperature will liquefy the grease and cause it to run into the bearings automatically. The length of the bearings or journal of the roller should be of a generous amount to allow for wear, and for most lengths of rollers should be shorter by not more than about 1½ to 2 inches. Thus, for a roller five inches long the bearing should be from three to three and a half inches in length.

Cast iron brackets support the hollow spindles which are secured by means of set screws or other suitable means, and the shape of the bracket will depend somewhat on local conditions and the nature of the stretcher which carries it.

Fig. 12 shows a cross section of the band with the material [illegible] This gives a very good idea of how the belt may be loaded.

Fig. 13 shows a patent carrier troughing roller, the [illegible]

Fig. 14 illustrates a usual arrangement of rollers for a flat belt. It will be noticed that these are of very simple construction.

[illegible]

[illegible] Manufacturing Company, and the writer is indebted to both this firm and the Dodge Manufacturing Company for the loan of the litho blocks given in this article.

It should be noticed that the roller sets shown in the last four figures are mostly made in sections, that is, they are not carried on one set of spindles in a single set of bearings. This enables the troughing rollers to be adjusted easily.

They are quite an important item of the installation, and on them depend to a large extent the proper transportation of the material and the life of the belt.

First and foremost, care should be taken to avoid any direct contact of the shoot with the band itself, as the constant rubbing on this would soon destroy the best fabric. At least one inch clear should be arranged at the loading end and for the delivery end a similar amount, if possible. To properly load the belt the shape of the shoot at the loading point should conform as nearly as possible to the direction of flow of the material at the instant it hits the band. If this is done easy loading and little spilling will be the result.

It will be found a good plan to provide ears on the sides of the shoot projecting along the path of the belt for about eighteen inches to two feet. These will have a tendency to keep the material in the centre of the belt until it has had a chance to settle down into its new direction.

Don't, on any account, try to feed the material on to the band at right angles to the latter, but arrange in such cases for the end of the shoot next the band to be curved round so as to get the flow in the same direction as the belt travels as nearly as possible.

Throw-off Carriages.—These are made in many ways and may be either of the fixed design, hand-gear propelled, or automatic power driven, the power being furnished by the band itself. They are used in cases where more than one point of delivery is required, namely, that at the end of the band. If only one additional point is needed then the stationary type can be used. If, however, it is necessary to deliver into several different hoppers in the line, then the traveling type becomes necessary, and if movement is only necessary at long intervals, the hand-geared traveling type will be found suitable.

Where, however, a small quantity has to be delivered at a number of different points in succession or a continuously moving carriage is necessary, then it will be found more advantageous to use the power driven carriage.

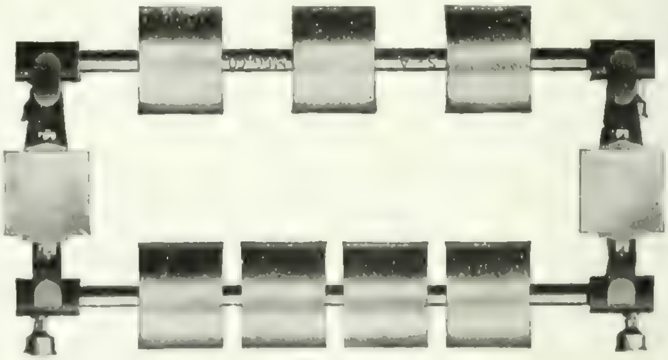

Fig. 14.

It will be an easy matter to settle which of these various types will prove the best for a given set of circumstances. These carriages consist of two pulleys, the shafts of which are mounted on a hinged frame and placed in such a position that it is possible to throw the pulleys clear of the band when they are not required. One pulley is arranged over the band and the other under. When it is required to use the carriage the hinged arm is revolved, the pulley on the top depressing the band and the one underneath raising it, thus making this portion of the band into the form of an ordinary meat hook shape or letter S.

On the carriage is mounted a shoot either of the single, breeches or three-way type, according to where it is required to deliver the material. If it is a breeches shoot, then the two legs straddle the band, the ends of the shoot being deflected enough to allow the band running away from the bottom of the S shape to pass between.

Sometimes the arms carrying the pulleys are not hinged but fixed in the delivery position all the time. In fact, it is possible to make a large number of arrangements to fit any particular circumstance. The traveling carriages are mounted on tee or bulb rails with ordinary flanged wheels to keep them on the track. Fig. 14 shows a tripper or throw-off carriage made by the Dodge Manufacturing Company, and Fig. 15 one by the Stephens-Adamson Manufacturing Company. The latter is of the reversible type.

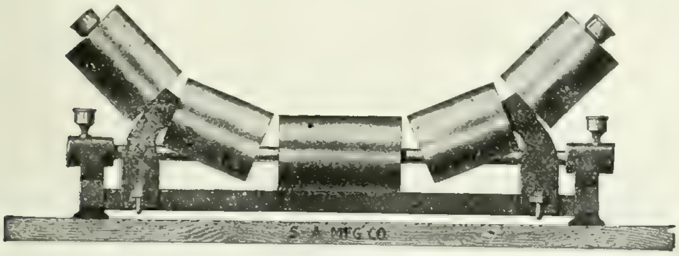

Fig. 15.

Distributors.—Sometimes it is necessary, owing to local conditions, to construct a hopper at the delivery end of the belt of square section, and if the dimensions are fairly large it is then sometimes a problem to utilize the full capacity of the hopper. There are various ways of doing this. For instance, the conveyor can be arranged at a suitable height above the top of the hopper, so that the natural slope of the material will fill it. Or, the conveyor may be run right across the hopper in one direction with points of delivery arranged all along by means of a throw-off carriage.

Or, again, another conveyor at right angles may be put in to divide the hopper into four equal parts.

Another ingenious contrivance consists of a revolving plate on the centre of which the material is fed from the conveyor. The plate is arranged horizontally and due to the action of centrifugal force throws the material outwards as it spins. The speed at which these plates should be run can be found by practical experiment for a particular material. It will readily be seen, however, that they will be of little use for large lumps of material, and for very fine a great deal of dust will be created. The use of these special appliances, however, is determined more by local conditions than anything else.

* * *

Expansion has marked the operations of the British Columbia Electric Railway Company during the past few years, the latest move being the purchase of additional land in New Westminster at a cost of $123,000 for car shop purposes. The company has found it very difficult to get delivery of cars from the manufacturers in the east, and it is proposed to manufacture cars here on a larger scale. With the big system it now has in hand, a very large number of new cars are constantly needed, for extensions are being steadily made and increasing traffic requires quicker schedules on the older established lines, necessitating more cars.

THE HEATING OF BUILDINGS.

A paper entitled "Observations on the Conditions of Guarantees," presented by Mr. A. H. Barker at the summer meeting of the Institution of Heating and Ventilating Engineers held at Southport, dealt with the methods at present in vogue for calculating heat losses from buildings, especially in their relation to the corresponding methods in current use for guaranteeing results.

Calculation of Heat Losses.—The method of determining heat losses now adopted consisted of calculating the amount of heat supposed to pass by conduction through walls, windows, doors, ceilings, etc., adding to this calculated loss another quantity supposed to represent the heat carried away by interchange of air, and estimating the radiating surface from the total number of B.Th.U. so found. The fundamental conditions assumed for the calculation were that the heat delivered to the interior of the room had been continued for so long a time that a constant rate of transmission had been established; in other words, that the amount of heat given by the radiator to the inner air in any one hour was not only equal to that given by the air to the inner surface of the wall, and in succession communicated by conduction from the inner to the outer surface of the wall, and from the outer surface of the wall to the outer air, but also that this flow of heat was constant as between any one hour and the next or any succeeding hour. It was also assumed that there should be no change in the conditions so long as the experiment lasted—that the outside temperature should be absolutely constant and that there should be no wind and no rain. But in practice the conditions did vary, and from this fact alone it followed directly that calculations for rate of heat loss from a room were purely imaginary, that such calculations did not, and indeed that no practicable calculations could, in fact, determine what the rate of transmission of heat actually was at any one time in any circumstances such as ever arose in practice. At the best such calculations only gave what would be the mean transmission in certain imaginary conditions. A still greater difficulty was the effect on the temperature at any one time of the heat capacity of the walls of a building. The amount of heat retained by walls of quite a moderate thickness enclosing a room of moderate dimensions was so considerable that even assuming the whole of the heat given off by a radiator in the middle of the room did not escape but was wholly absorbed in warming up the walls to a temperature half-way between the inside temperature and the outside temperature, it would commonly take several days at full power merely to warm up the walls. Then it was necessary to inquire what was the effect on the temperature of the wall when the outside temperature varied up and down within wide limits as it always did in practice. Obviously the flow of heat into and out of the wall from the inside as well as from the outside would be so irregular that no conceivable process of calculation could determine beforehand what the result would be at any particular time, for the data could not possibly be known in advance. If the exact value of the external and internal temperature throughout a long period of time could be known with some accuracy, the mathematician could probably make the calculation if he had a week to spare to do it in, but in no other circumstances would it be possible, and no person but an expert mathematician could make the calculation at all. Further, the output of heat from the radiator or other warming apparatus in the room was not constant but irregularly intermittent, the furnace was allowed to go down two or three hours during the day, and almost always during the night it was banked up so that it gave off very little heat. This additional factor added enormously to the complication of the problem.

The Question of Guarantees.—The main object of the author was to show how entirely absurd from a practical or scientific point of view were the guarantees which an engineer was accustomed to give to a client or an architect in regard to the efficiency of his apparatus, and how wholly such guarantees were dissociated from the facts and conditions on which the engineer based his calculations. The standard guarantee stated that the apparatus would maintain the room at a temperature of 60 deg. when it was 30 deg. outside. If the engineer was very scientific he added that the rate of interchange of air should not be more than perhaps twice per hour, and sometimes as an additional precaution he claimed that the outside air should be still. The real meaning of the guarantee, strictly construed in accordance with the facts of science, was that if the outside temperature remained constant, the air dry and still, for a sufficient time, say a fortnight, and if the apparatus was maintained at full power day and night all the time, the internal temperature would gradually approximate to a point at least 30 deg. above the outside temperature, whatever that temperature might be. On the other hand, the client expected the guarantee to mean that if at any time within a few hours of starting the apparatus he fixed two thermometers, one inside and the other outside the rooms heated, the latter would read 30 deg. higher than the former, irrespective of conditions. Suppose the outside temperature had for a fortnight been 50 deg., and on the day of the test suddenly dropped to 30 deg., the difference in the temperature of the same room on the two occasions might be 30 deg. if the same apparatus had been continually at work all the time at the same power in each case and although the external temperature at the time of the observations was the same in each case. The difference in the result would be entirely due to the amount of heat retained in the walls of the buildings. Yet of this all-important factor the orthodox calculations and the orthodox guarantee and the orthodox test (if there was such a thing) took no account whatever.

The author's own opinion was that the only satisfactory solution of the problem was that the engineer should guarantee only that he would furnish a scheduled number of B.Th.U. to each room, and that the test should consist of a careful measurement of the temperatures in the flow and return pipes, the surface of the radiator, and the difference between the temperature of the room and of the radiator at the time. The B.Th.U. emitted in such conditions should be calculated from standard co-efficients. When the scheduled numbers of B.Th.U. had been delivered to each room according to this calculation, then and not till then, the en[illegible] weather conditions at the time, and irrespective of the temperature [illegible] B.Th.U. [illegible] guarantee of fuel consumption, and such a guarantee would be [illegible] B.Th.U. [illegible] B.Th.U. [illegible]

client's own responsibility and had nothing whatever to do with the heating engineer as such.

One obvious objection to these proposals was that the client cared nothing about B.Th.U; he only wanted his house warmed to a certain temperature. A client might as well say that he did not mind how much food he paid for; he only wanted his children properly fed. This argument would be all very well if the cost both of apparatus and upkeep was a matter of insignificance, and the heating engineer might very well be held responsible altogether if he were an insurance company who would make an expert examination of the premises with the insurance in view and charge a premium for the insurance. But the trouble was that the lack of understanding of this problem was so complete that at present the engineer took the risk without getting the premium, and very often it was to be feared did not even know that he was taking the risk.

VALUE OF COAL ON A COKE BASIS.

In the course of an address at a meeting of the Waverley Association of Gas Managers, held at Edinburgh on Friday last, Mr. J. W. Napier, of Alloa, raised the question of the buying of coals on the basis of the values of residuals. It was well known, he said, that coals from different seams varied in the percentage amount of what might be termed natural water. If they took the average amount of water present in coals at 5 per cent., this was equal to 13.44 gallons, or 134.4 lbs. of water per ton of coal. A coal with 12 per cent. of water would contain 269 lbs. of water per ton and, compared with the standard of 134 lbs., would show an excess of 135 lbs of water. At 12s. per ton purchase price, the plus quantity of water cost fully 8d. per ton, and this extra charge for mere water was appreciable.

Coke was justly looked upon as the most valuable of all the residuals. With a selling value of 10s. per ton for coke, a difference in yield of 1 to 2 cwts. of saleable coke between different coals made an appreciable difference in the revenue account. The amount of coke produced from coal could easily be determined, even in the smallest works. It required only a weighed quantity of coal to be carbonized in the retort and the coke produced weighed.

In the analysis of a number of coals that had passed under his examination from time to time, in ascertaining the coke produced per ton of coal, he had been struck with the difference between what he might call the "analysis" value and the "saleable" value of the coke produced, and more particularly from nuts and so-called coking dross. For example, one material which gave a yield of 13.1 cwts. of coke, which on analysis showed carbon 96.65 per cent. and ash only 3.35 per cent., would be taken as of excellent value. On putting the material through a trial test in the retort and examining the coke produced, the following results were obtained:—

Saleable coke per ton of coal produced ... [illegible] cwts.
Breeze ... [illegible] cwts.

Percentage of breeze = [illegible]

This [illegible], but the example was valuable as showing the need for ascertaining the absolute market value of the coke. Another example was the following:—Coke per ton of coal, 12.5 cwts.; carbon in coke, 88.71 per cent.; ash, 11.29 per cent. On further examination, to ascertain the saleable amount of coke, the following was the result:—

Saleable coke per ton of coke made ... [illegible] cwts.
Breeze ... [illegible] cwts.

Percentage of breeze = 18.4.

The third example was as follows:—Coke per ton of coal, 12.7 cwts.; carbon in coke, 91.4 per cent.; ash, 8.6 per cent. Examination for value of saleable coke resulted as follows:

Saleable coke per ton of coke made..............	19 cwts.
Breeze " " "	1 cwt

Percentage of breeze = 5.

The breeze was determined by the amount passing through a ¾-inch mesh riddle.

Again, it would be observed that though gas-making material yielded a satisfactory weight of coke, on submitting the coke to a critical examination, a very serious loss to the purchaser would result. With coke selling at 12s. per ton, the breeze at 2s., or a difference in value of 10s., each hundredweight of breeze produced was equivalent to a loss of 6d. per ton of coke, one coke compared with another. It could easily be seen, therefore, how a difference in value of 1s. to 2s. per ton of coal might be brought about from this source alone. He had not referred to the presence of an excess amount of breeze being unsuitable for the working of producers, but this would undoubtedly be the case.

In carrying out the tests referred to the physical character of the coke was noted as of importance, some of the cokes produced being soft and easily broken. Incidental to the amount of breeze produced in gasworks where coke-handling appliances were at work, the physical character of the coke was all-important, as upon this depended the amount of breeze produced, and he had endeavored to show that great loss might accrue from this direction, to which, he ventured to think, sufficient attention had not been devoted. The amount of saleable coke per ton of coal was of vital importance at the present time, not only because of the higher price to be paid for coal, but also on account of the fact that coke might be expected to yield an extra value of about 3s. per ton.

Before departing from the subject of coke, it might be of interest to compare coke made in vertical retorts with what was known as "malting" coke, which realized a high price. The vertical retort coke was produced from the coal ordinarily used at the Alloa Gasworks, and was a sample from a trial test in the experimental vertical setting at Temple Gasworks, Glasgow.

	Vertical retort coke.	Malting coke.
	Per cent.	Per cent.
Carbon	89.20	91.25
Volatile matter	1.05	0.80
Water	0.35	0.15
Ash	9.40	7.80
	100.00	100.00

The sample of malting coke was made from the well-known Bannockburn coal. Malting coke was at present selling at fully 20s. per ton, and vertical retort coke of almost the same quality—as the above analyses showed—should command a high price. This advantage of vertical retort carbonization was best seen by a comparison of the prices of coke produced by that system and coke made in horizontal retorts, selling at only 12s. per ton. He ventured to say that the vertical retort would enhance very much the value of coke, at least in the particular market referred to.

Tar was realizing a high price at present, having increased from 11s. to 17s. per 100 gallons during the last twelve months. The latter price was equal to 2d. per gallon, and the difference in value between coals of high and low yield of tar could at once be appraised.

SELECTION OF ELECTRIC LOCOMOTIVE FOR INTERURBAN FREIGHT HAULING.

In selecting a locomotive and its equipment for interurban freight service, the characteristics of the track, curvature, grades, and the rail weight, strength of bridges, etc., must be considered. The following information is abstracted from a bulletin published by the Railway Department of the Westinghouse Electric and Manufacturing Company. The maximum current which the locomotive can safely take from the substations should be known. It is also advisable to know the probable tonnage to be handled daily in each direction, and at what points it will originate and be delivered. From this information the locomotive can be selected.

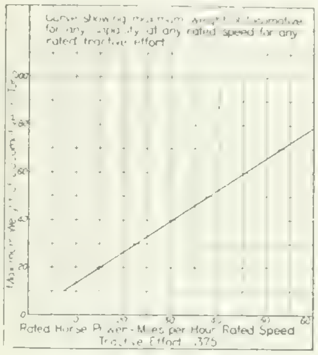

Fig. 1.

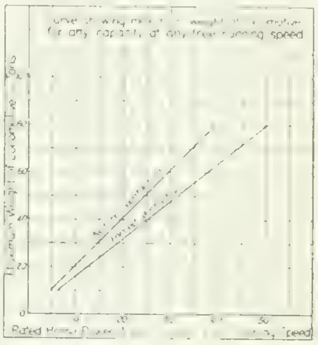

Fig. 2.

The examples given in paragraphs that follow indicate an approximate method of procedure. The curves of Figs. 1 to 7 are used. These give, approximately, maximum locomotive weights and minimum capacities. Results for any specific case may be materially altered by local conditions. In using the curves it should be observed that the gear ratio must be so chosen that the desired speeds will result. In general, the lowest speed gear that an equipment will take is found most suitable for locomotives.

Case I.—Practically Level Road. Horsepower of Motors and Speed in Miles per Hour Known. Find Weight of Locomotive and Trailing Load. Assume that a spare equipment of four 60-horse-power motors is available for locomotive service and that the speed of the equipment at its rated horse-power and voltage is 11 miles per hour. What is the maximum weight of locomotive suitable for this equipment? The rating of the locomotive is 240 horse-power. The rated horse-power divided by the rated speed is 240 ÷ 11 = 21.8. From Fig. 1 it is evident that when the horse-power divided by rated m.p.h. is 21.8, the maximum weight of locomotive is 28.5 tons.

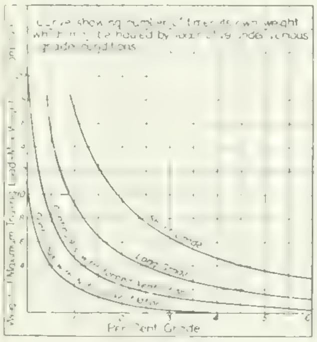

Fig. 3.

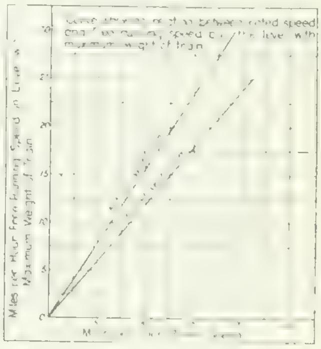

Fig. 4.

The next question is, what load can this locomotive haul? To answer this definitely requires an exact knowledge of the profile of the road. Suppose that the road is practically level except for some over-crossings where there are grades of 2 per cent. for 1,500 to 2,000 feet. The curve for short grades on Fig. 3 is used. At 2 per cent. this curve shows that the locomotive can haul 9.6 times its own weight or the maximum trailing load is about 9.6 x 28.5 which equals 273 tons. The average loaded freight car in many sections is of from 35 to 40 tons gross weight, so it appears that this locomotive can haul seven or eight average loaded cars.

The above determination of tonnage should be checked against the load which the locomotive can handle continuously under average conditions. The assumption was made that the road was practically level. Assume further that the motors are naturally ventilated (no blowers used). The curve on Fig. 3 for continuous natural ventilation shows that at 0 per cent. grade (level) the locomotive will haul 11 times its own weight or 313 tons. Hence, in this case the short 2 per cent. grade is the feature limiting the tonnage. To find the speed running free on the level with the maximum tonnage use Fig. 4. This shows 17 m.p.h.

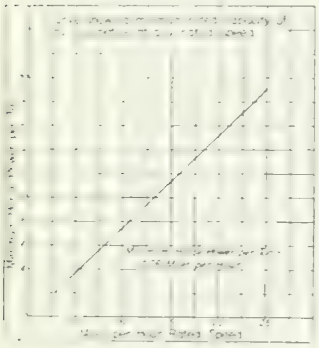

Fig. 5.

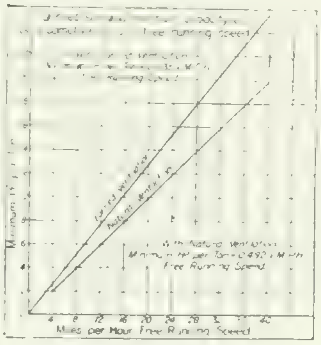

Fig. 6.

Case II.—Rolling Profile. Horse-power of Motors and Speed in Miles per Hour Known. Find Weight of Locomotive and Maximum Trailing Load. Suppose the road is not practically level, but is in a rolling country and that in addition to the short 2 per cent. grades, there are a number of grades of 1.25 per cent., each being from 2 to 2.5 miles in length. Fig. 3 shows that the maximum trailing load on long grades of 1.25 per cent. is 7.7 times the locomotive weight, or 220 tons. If, under these conditions, the two ends of the road have nearly the same elevation, the equipment will probably haul the load of 220 tons continuously with natural ventilation. If, however, the ends of the line have considerably different elevations, forced ventilation may have to be applied or the average load reduced [illegible]

Case III.—Speed and Locomotive Weight Known. Determine Minimum Equipment. Suppose a locomotive with a rated speed of 14 m.p.h. is desired and that the construction of the roadway limits the weight of [illegible] tons. What is the minimum equipment for such a locomotive? Fig. 5 shows that at 14 m.p.h. the minimum rated horse-power per ton is [illegible]. Hence, the rating of this [illegible]-ton locomotive should not be less than [illegible] horse-power and the equipment [illegible] horse-power motors. The performance of this equipment under the conditions pertaining to the road it operates may be determined as previously described. If it is not sufficiently large, more powerful motors may be installed up to the point where the dimensions and weight of the equipment would require a locomotive having a minimum weight of [illegible]

Case IV.—Profile and Trailing Load Known. Find Weight of Locomotive. Assume long and short grades as in Case II. What weight of locomotive will be required to handle 500 tons trailing load? Further, assume that the nature of the road is such as to be equivalent to a continuous pull up a 0.3 per cent. grade. What is the minimum equipment for a locomotive if forced ventilation is used and the free running speed on the level is 12 m.p.h.?

The short grade curve in Fig. 3 shows that a locomotive will handle 9.6 times its weight on the maximum grade. The continuous forced ventilation curve of Fig. 3 shows that on a 0.3 per cent. grade, the locomotive will haul 10.7 times its own weight. Hence, the short 2 per cent. grade fixes the locomotive weight and this should not be less than 500 ÷ 9.6 = 52 tons. Fig. 5 shows at 12 m.p.h. with forced ventilation, the minimum equipment should have 7.6 horse-power per ton. Hence, the locomotive should rate (7.6 x 52) 395 horse-power. The equipment should be four 100-horse-power motors, geared for 10 m.p.h. rated speed and provided with forced ventilation.

The current demand for a freight train depends primarily upon the speed, train weight and grades, and secondly upon the alignment, average weight of car, frequency and duration of stops, etc. The size of locomotive, speed and train weight should be adjusted to the capacity of substations and line in so far as the demands of the traffic will permit. The curves on Fig. 7 will be found useful in selecting the maximum weight of train to be handled within any fixed current limit.

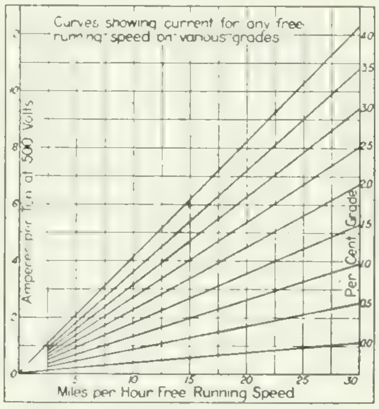

Fig. 7.

Example.—Suppose the maximum grade on a road is 3 per cent. for 1.5 miles and it is so located that all the power for climbing it must be taken from a 500-ampere substation. A speed of 8 m.p.h. is desired on this grade. For such a grade, the substation may work at 50 per cent. overload; i.e., deliver 750 amperes. Fig. 7 shows that at 8 m.p.h. on a 3 per cent. grade 2.5 amperes per ton are required. Hence, the maximum weight of train at this speed is 750 ÷ 2.5 = 300 tons, including the locomotive weight. If 6 m.p.h. were sufficient speed, 415-ton trains could be operated. If 12 m.p.h. were desired, the train weight would be limited to 200 tons. So the effect of speed on power demand is apparent. For any specific proposition, therefore, the choice lies between speed and tonnage in a single train.

NEW SHAPE OF RAILROAD RAILS TO PREVENT BREAKING.

Engineers of the Harriman lines in the United States have found that the base of a regular 90-pound rail tends to become bowl-shaped in cold weather, and the pounding of the wheels causes surface fractures. By broadening the base of the rail and making it heavier, the breaks are reduced to a minimum. Mr. Kruttschnitt is reported as saying: "We find that the rail with the heavier base gave only two breakages to the 100 miles in the winter months (as compared with [illegible] breakages in the regular rail), the same rate as during the summer months, so that, so far as the Harriman lines are concerned, the rail problem is solved. We feel that we have solved the problem for all the roads."

OZONE: ITS PROPERTIES AND COMMERCIAL PRODUCTION.*

By Milton W. Franklin.

The importance of ozone as an industrial factor in certain lines of engineering is becoming appreciated quite rapidly. The relatively large number of patents which are being applied for the increasing number of advertisements which are appearing and the character and standing of the electrical manufacturers who have entered the field, all point to a realization of Berthelot's prediction that ozone was destined to enjoy a great vogue in its application in the arts and sciences. The commercial future of ozone may be regarded as assured. The many actual applications which have already been made and the numberless fields for its logical invasion, together with recent developments of perfected ozone generators all indicate the growing consideration which this reagent is gaining for itself.

Ozone has been known since 1785, when Van Marum noted the peculiar smell which resulted whenever a static electrical machine was operated, and while its identity was fully established by Schoenbein in 1845 and a method for its analytical determination was developed by the same investigator, it has not enjoyed any extensive application, excepting on an experimental scale, until approximately within the last ten years. This delayed recognition may be attributed to the lack, at the time, or perfected ozone generating apparatus and to the absence of commercial electricity.

The primitive ozone apparatus was designed to produce a phenomenon, the discharge of electricity through air, which, it had been noticed, was ordinarily accomplished by the production of ozone.

It was seen early that the amount of ozone produced in the naked arc, either high or low tension, was relatively small as compared with that due to the brush or "silent" discharge, and the constructional and manipulative difficulties accompanying the production of and operation of static condensers are probably responsible for the introduction of a solid dielectric interpolated between the statically charged plates if the modern ozone generator.

There does not appear to have been any very erudite opinion on the modus operandi of ozone generation among the early designers and the prevalence of the type in question, viz., that with smooth electrodes and solid dielectrics, seems to be due to a desire to produce an electric field of considerable extent, in which the discharge should be uniformly distributed.

It has also been apparent for some time that, at certain elevated intensities, the appearance of noxious nitrogen oxides became manifest, and the objectionable circumstances was ameliorated by lessening the potential difference and increasing the interpolar spacing of the electrodes.

The scientific design of ozone generators as distinguished from the purely empirical method is of very recent inception and its beginning, naturally, is somewhat obscure. There have appeared creditable machines for the purpose, in advance of any theoretical information as to the principal involved.

Production of Ozone: Ozone Generators.—Ozone may be produced by chemical means, by the electrolysis of water and by the action of the electrostatic field on air or on oxygen.

Slow oxydations, as of phosphorous, produce ozone. The process is a curious one and has been studied by Schoenbein, who noticed that when certain substances are oxidized by air a portion of the oxygen combines directly with the substance undergoing oxidation, while another portion of the oxygen forms ozone. Thus ozone is formed during the oxidation of numerous substances. Schoenbein also enunciated the law that precisely the same amount of oxygen is converted into ozone as combines with the substance oxidized. This law has been verified by several other observers for phosphorous, aldehyde, triethylphosphine, turpentine, amylene and numerous other organic substances, and for sodium sulphite, ammoniacal cuprous oxide, etc., in the process of auto-oxidation.

About the only practical application, however, of the chemical production of ozone, has been by means of fluorine. Moisson has obtained fluorine by the electrolysis of anhydrous hydrofluoric acid. Fluorine attacks powerfully all organic materials and decomposes water, combining with its hydrogen to form hydrofluoric acid and at low temperatures, the oxygen forms ozone. The reaction is as follows:

$$3\ H_2O + 6\ Fl = 6HFl + O_3$$

In the preparation of ozone by the decomposition of water by fluorine, the fluorine is introduced in a thin stream into the water which is maintained at a temperature of O°C.

Recent improvements in fluorine generators have made the method practicable but it does not compare in economy with the electrical methods of ozone production.

The Electrolytic Production of Ozone.—Ozone is formed along with the oxygen in water electrolysis. The presence of ozone accounts for the low reading for oxygen obtained when the electrolyte is too strong in sulphuric acid and the current density too high.

The first recorded observation of ozone in water electrolysis was by Schoenbein in 1840. More recently ozone has been obtained by alternating current electrolysis of acidulated water.

In some of the electrolytic processes at Niagara Falls the presence of ozone has been strongly manifest, though there is no recorded mention of its having been used for any industrial purpose.

In the production of ozone by electrolysis, the anode must be of some substance not oxidizable, such as platinum, gold, etc., and the electrolyte must contain no matter which is capable of combining with the ozone.

In certain special applications, ozone prepared by electrolysis seems to be more active and suitable than that prepared by the commoner electrical methods, but the reasons are obscure and the cases uncertain. The method is not economical and has found no general application though higher concentrations are obtainable than by other ordinary procedures.

Electrostatic Production of Ozone.—The common method of ozone production for industrial purposes is by the action of the electrostatic field on air or oxygen.

The types of machines that have been devised are almost without number, ranging from those utilizing the high frequency discharges of the Oudin and Tesla resonators to those making use of the "effluve" or the silent discharge of a leaky condenser with or without solid dielectrics. The variations and the combinations of the fundamental types are too numerous to mention, even, and only a few or the more useful and striking examples will be described.

The ultimate theory of the electrical formation of ozone is still somewhat obscure and it may be said that whatever definite information there is on the subject is rather of a negative than a positive character: e.g., Warburg and Leithauser have shown that the process is not an electrolytic one. The equivalent weight of ozone is 24, and, therefore, if the process were an electrolytic one it would require the electrochemical equivalent, 96,540 coulombs, for the production of one mole, 24 gm., of ozone. In actual practice, however, as much as 130 gm. per kw. hr. has been obtained, which, under the conditions of the operation, corresponds with 240 coulombs only, or the equivalent of ozone has been obtained with about 44 coulombs. This number is far too different from the electrochemical equivalent to be a matter of experimental variation.

---

* A paper presented at the Schnectady meeting of the American Institute of Electrical Engineers, Schnectady, N.Y., May 17th, 1912.

The view is generally held that the process is one of ionization and recombination. There appears a disassociation of the oxygen as soon as the action of the electrostatic field becomes sufficiently intense to cause ionization by collision, and there result numbers of ions from the disassociated molecules. These ions attach themselves to the molecules with which they must inevitably collide and thus form ozone which, on this view, may be composed of aggregates of odd numbers of atoms of the general formula, $O (2n + 1)$.

The relation between the quantity of ozone produced and the quantity of current has been the subject of considerable speculation, but no perfectly satisfactory hypothesis has been advanced. Warburg has advanced the theory that the ozone is formed by those electrons which have attained a certain critical velocity, viz., that at which luminosity ap[illegible].

Ozone is an endothermic compound and, therefore, the equilibrium concentration is greatly increased under certain circumstances, as for example, the influence of the electrostatic field, especially if the temperature is kept low so as to lessen the destructive forces as compared with the constructive forces.

The silent discharge or "effluve" of the French writers, is the conduction of electricity through gases at low and moderate pressure. The phenomena vary with the electrical and physical dimensions, and with the conditions generally, of the electrical and gas pressure. The discharge is quiet and the gas attains a dark violet luminosity. If the pressure is comparatively low the discharge between a point and a plate will be of this nature but the electrical polarity of the point exerts an influence. The discharge between plane parallel or curved concentric surfaces is generally of this character, and when a dielectric is interposed between the plates, the formation of sparks is effectually prevented.

The question as to whether or not a dielectric should be used has been the cause of considerable experimentation and discussion but the general consensus of opinion at present is that the use of the dielectric increases the efficiency [illegible]

Forms of Ozonators.—One of the first ozonators with [illegible] This ozonator (Fig. 1) consists essentially of [illegible] dilute sulphuric acid, and the outer tube, a, [illegible] the sources of current. When the potential difference is sufficiently high there is a luminous silent discharge in the gas in the annular space between the tubes and there is the formation of ozone.

Fig. 1.

The general principles of this ozonator have been retained in some of the later commercial types, e.g., the Gerard ozonators.

The Siemens and Halske ozonators (Fig. 2) consist of a central metallic cylinder surrounded by an annular air space in which the electrical discharge takes place and through which the gas to be ozonized is passed. The outer boundary of the air space is a cylinder, concentric with the central core and in turn surrounded by a water jacket which serves to keep the temperature within proper limits. The potential is applied between the central core and the water surrounding the outer wall of the air space, and the latter may be of glass or of metal. In the latter case there is supplied a lining of glass which forms the dielectric. This type of ozonator has had considerable commercial application and is used in the installations at Wiesbaden-Padderborn, St. Petersburg, etc. The whole oxonator is enclosed in a metallic case which is furnished with inlet and outlet tubes for the air and the ozone.

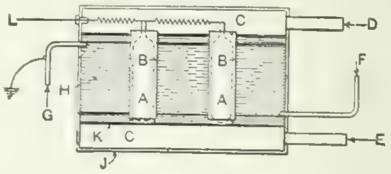

FIG. 2.

A—inner electrode, *B*—outer tube, *C*—ozone space, *D*—air inlet, *E*—air outlet, *F*—water inlet, *G*—water outlet, *H*—water, *J*—outer casing, *K*—partition, *L*—high-tension lead.

The Gerard ozonator has appeared in several commercial forms which differ from each other in minor constructional details. It consists essentially, of two concentric glass tubes about one meter in length; and the outer tube has a diameter of approximately 8 cm. The annular space between the tubes in which electrical phenomena take place varies from three to five mm. in the various modifications. The electrodes are metallic coatings affixed to the outer surface of the outer tube and to the inner surface of the inner tube respectively.

An example of an ozonator without dielectrics is that of De Frise, (Fig. 3). This consists of a trough, semicylindrical in cross section and furnished with a water jacket for cooling. A glass cover closes the trough and from this are suspended a number of semicircular metallic disks which may have smooth or serrated edges. These disks are arranged in parallel planes and are spaced at about one cm. The flat edges are fastened to the glass cover and the curved edges together form a ribbed semicylindrical surface, which, when in position, comes to within five mm. of the bottom of the trough, with which it is concentric. The electrical discharge takes place between the edges of these disks and the bottom of the trough, and the air to be ozonized is drawn through the space which intervenes.

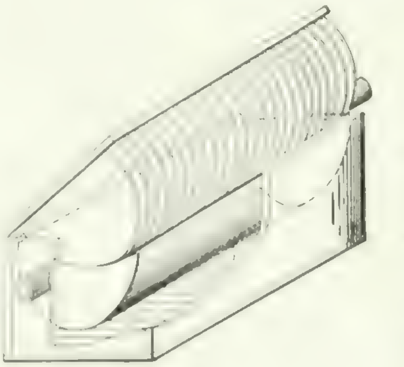

Fig. 3.

There have appeared from time to time, ozonators with devices for obviating the necessity for the solid dielectric. [illegible] has designed several in which the electrodes move with respect to each other, or in which one moves and the other remains stationary. Fig. 4 is a diagram of one of these. It consists of a metallic casing which forms one of the electrodes, and a series of metallic disks mounted parallel on a shaft by which they are rotated. The disks each have two sectoral windows, diametrically opposite each other, cut from them, and when assembled, form the other electrode. The disks are beveled at the edges, and the windows are staggered with respect to the disks which are adjacent. This arrangement assures that if a spark forms at any point, it will be drawn out and ruptured by the rotation of the disks.

Ozonators without solid dielectrics and with rotating electrodes have as yet enjoyed no very extensive application. The absence of the dielectric seems to favor the production of nitrous oxides notwithstanding the precautions to the contrary, and the extra power required to rotate the electrodes does not seem to be compensated for by any corresponding gain in another direction.

Besides the ozonators which have been mentioned there have appeared numerous others, as those of Andreoli, Tisley, D'Arsonval, Tindal, Otto, Vosmaer, etc., but all of the successful commercial types have tended to the same general design, namely, metallic electrodes with smooth surfaces and interpolated solid dielectrics.

All the ozonators which have been mentioned above are for the production of ozone on a large scale and at relatively high concentrations, and are in general intended for the purification of drinking water and for analagous industrial applications. Latterly, however, the subject of purifying and refreshing the air of localities which suffer from overcrowding, inadequate ventilation, and the introduction into the air of the noxious products of industrial activity, has engaged the attention of sanitarians to a considerable extent. From a consideration of the theoretical causes of the objectionable character of such air and the essential properties of ozone it has become evident to many experts that ozone offers a remedy for the conditions, and one which possesses many advantages of simplicity, efficiency and economy. There has resulted, in consequence, the development of numerous ozonators for the specific purpose of treating the air of populated spaces.

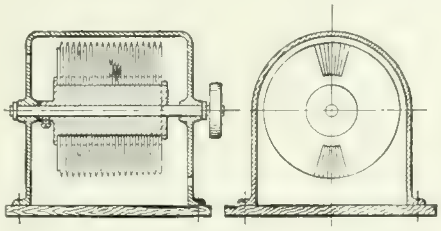

Fig. 4.

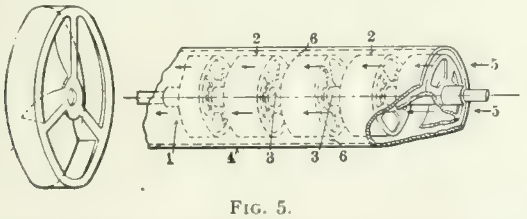

Fig. 5.

1—glass tube; 2—aluminum cylinders, inner electrode; 3—spacing collars, 4—metal coating, outer electrode; 5—direction of air flow, 6—air-gap, 7—enlarged view of 2

The requirements in these small ozonators differ in several important particulars from those demanded in the larger machines. The instruments are, in general, put into the hands of unskilled persons and they must, therefore, be simple, durable, self-contained and automatic to the greatest obtainable degree. They must be small, fireproof, free from danger and reliable in operation, and all of these properties must be possessed in a measure far surpassing that required in the larger machines intended for operation by skilled electricians. Under no circumstances must they produce nitrogen oxides and this prohibition also precludes the employment of means for removing the objectionable by-products after they have been formed in the machine.

Most of these desiderata such as safety, durability, simplicity, space economy, etc., etc., may be obtained by operating at low voltages. To employ low voltages at the frequencies commonly met with in commercial installations, and at the same time to obtain the electrostatic field intensities requisite for the production of ozone, the length of the field in a direction normal to the electrode surfaces must be shortened. This shortening ordinarily has the disadvantage that it lessens the volume of air that may be treated with respect to a given area of electrostatic field and consequently affects adversely the consideration of space economy. Fig. 5 shows a method by which the field has been shortened to a value limited only by the inability of the glass-blower to produce more accurate tubes, without at the same time curtailing the ozone production capacity of the ozonator. The cut represents one form of unit used in the General Electric air ozonators, an assembled machine being shown in Fig. 6.

Referring to Fig. 5, the potential is applied between the metallic coating of the glass tube, 1, and the metallic inner electrode, 2, which is formed of a series of cups of a special design. The electrostatic field is formed in the space, 7, which has a clearance of the order of 0.4 mm. so that with comparatively low voltages the potential gradient may be extremely high. The air to be ozonized is blown along the axis as shown by the arrows, 5, and the peculiar vane shape of the spokes of the cupped electrodes causes a constant intercommunication between the new air and that which has been ozonized in the ozone spaces.

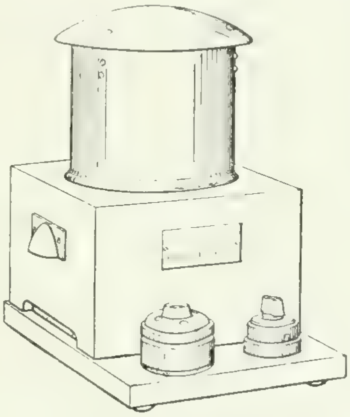

Fig. 6.—Alternating-Current Household Ozonator.

Ozone is an allotropic form of oxygen with the formula O_3, as was established by Schenbein. The nature of ozone was for a long time debated but the researches of Andrews and Tait, Marignac and De la Rive, Brodie, Fremy and Becquerel and particularly those of Schoenbein showed conclusively that when oxygen was converted into ozone, the volume was reduced one-third, and analysis failed to show the appearance of combinations with other elements. Ozone is a faintly bluish gas with a characteristic smell and it was this circumstance that led to its discovery. It has never been obtained in the pure state but it is always mixed with ozygen from which it is derived.

Hautefeuille and Chappuis, on compressing ozone to 125 atmospheres at the temperature of boiling ethylene (— 103 deg.) have obtained a dark blue liquid with highly magnetic properties. The compressed gas above the liquid was also of the same intense blue color, and both the compressed gas and the liquid were highly explosive. When the pressure is removed and the temperature allowed to rise, the liquid soon evaporates.

Ozone is relatively stable at ordinary temperatures when remote from organic or other oxidizable substances, but becomes unstable at elevated temperatures and decomposes into ordinary oxygen. The decomposition is instantaneous at 260 deg.

Ozone possesses enormous chemical activity as compared with ordinary oxygen, for the reason that it parts with the extra atom of oxygen very readily. It is an endothermic [illegible] and the endothermic heat has been investigated by numerous chemists including Berthelot, van der Meulen, Jahn and others. The mean value of the endothermic heat as obtained by numerous methods is 33.380 calories per grammolecule.

Ozone is only slightly soluble in water. Recently, E. Maufang has investigated the subject and found that the solubility of ozone in water is proportional to the temperature and pressure, and conditioned by the chemical composition of the water; a concentration of 1.5 to 10 mg. per liter of water may be regarded as the solubility coefficient at ordinary temperatures (2 deg. — 28 deg.)

The chemical analysis and the volumetric determination of ozone as worked out by Schoenbein in 1845 was the subject of some difference of opinion and discussion, but in 1872, Brodie verified the results and established the theory. Later, 1901, the discussion having again arisen, Ladenburg and Quasig covered the same ground with the same result, though they appear to have been unacquainted with the work of Brodie. Treadwell and Anneler, in 1905, checked all previous results and finally established the correctness of the method of analysis which is now in general use.

The analysis depends on the following reactions:

$$2\,KI + O_3 + H_2O = 2\,KOH + I_2 + O_2 \quad (1)$$

and

$$2\,Na_2S_2O_3 + I_2 + 2\,KOH + H_2SO_4 = Na_2S_4O_6 + 2\,NaI + K_2SO_4 + 2\,H_2O \quad (2)$$

which in actual practice reduce to the following volumetric equation:

$$1\ cc.\ \frac{N}{10}\ Na_2S_2O_3 = \frac{O_3}{20} = [illegible] = 2.4\ gm.\ O_3 \quad (3)$$

The commercial value of ozone consists in the fact that it is so powerful an oxidizing agent that many of the reactions of oxidation which take place with ordinary oxygen only on the addition of heat, may be effected with ozone without previous heating, and in a much shorter time.

The many applications of ozone have been adequately treated in previous publications and aside from the purification of air and water they are of general interest to the chemist rather than to the engineer, and will not be dilated on here.

The fact that there was transacted about seven million dollars' worth of business in ozone apparatus in Europe last year indicates the trend of modern thought with respect to ozone.

* * *

CROSS-TIES USED BY RAILWAYS

There were 9,213,962 cross-ties, costing $3,535,628 purchased in 1910 by the steam and electric roads of Canada. [illegible] per cent. from the number purchased in 1909, due to the decreased purchase of ties for new steam railway lines.

This decrease was general throughout the important species except with Douglas fir. The average cost of these [illegible] an increase [illegible] 1909.

The data upon which the report, compiled by Mr. H. R. [illegible] were [illegible] of Canada. The [illegible] the point of purchase.

[illegible] per cent. of all the ties [illegible]. These were cedar, jackpine and hemlock. [illegible] used in Canada. In [illegible] per cent. in 1909. Nearly all the cedar used is eastern cedar (Thuja occidentalis), as western cedar (Thuja plicata) is too soft for satisfactory use as cross-ties, except for electric lines where the traffic is light.

Jack pine is the second in importance in cross-tie production. In 1910 it supplied 23.5 per cent. of the ties used in Canada, which was practically the same percentage as used in 1909.

Hemlock, supplying 13.8 per cent. of the total consumption, occupied third position in 1910. Hemlock has now for the first time passed tamarack as a tie-producer. The advance of hemlock from the fourth position, which it previously held, is due not to an increase in the use of hemlock, but to a decrease in the use of tamarack. Douglas fir formed 9.6 per cent. of the ties purchased in 1910 as against 4.6 per cent. in 1909. About 232,000 more Douglas fir ties were purchased in 1910 than in 1909. This species was used to a greater extent by both steam and electric railways. Tamarack ties have dropped from third place in 1909, when they formed 19.8 per cent. of the total, to fifth place in 1910, when they formed only 7.1 per cent. In 1910 only 663,922 tamarack ties were purchased, compared with 2,811,820 purchased in 1909. This great decrease of 2,147,898 ties is found entirely in the number used by steam roads, and is due to the fact that the purchase of ties for the eastern half of one of the new transcontinental roads was completed previous to 1910. The above five species, namely, cedar, jack pine, hemlock, Douglas fir, and tamarack, represent 94 per cent. of the total number of ties used. Nearly all the remainder is made up of oak and spruce.

The number of oak ties purchased in 1910 was 264,647, or an increase of 230,258 over the number purchased in 1909. This is due to one United States Railway, operating in Canada, which is using a great proportion of durable woods. Aside from this road the railways of Canada use oak ties chiefly for switch ties. The use of spruce, one of the cheapest ties, has fallen off greatly, 657,871 ties less being purchased in 1910 than in 1909. The decrease in the purchase of spruce is due to the same reason as that ascribed to tamarack.

The remaining species, cypress, chestnut, and white pine, are used to a small extent for ties. All the cypress and chestnut ties and practically all the oak were imported from the United States. Red pine and yellow pine, which were used in 1909, were not reported in 1910. The average price of ties in 1910 was 38 cents as compared with 37 cents in 1909. Of the important woods oak cost the most, 74 cents per tie, and spruce the least, 28 cents per tie. Cedar cost 41 cents per tie, as compared with 45 cents per tie in 1909. Douglas fir cost 30 cents per tie in 1910, or 4 cents less per tie than in 1909. The remaining woods, or all excepting these two, have advanced in price from 3 to 12 cents per tie.

The electric railways used four per cent. of all the ties purchased [illegible] ties were used by electric roads [illegible] an increase of 182,[illegible] cedar and Douglas fir. This [illegible] construction. Nearly 50 per cent. of the total number used were cedar ties at a cost below the average, namely, [illegible] cents.

Douglas fir constituted [illegible] per cent. of the total. Jack pine, [illegible] from the electric railways, was used only to the extent of 0.6 per cent., the ties costing 51 cents each. In steam roads [illegible] per cent. of the ties used were jack pine, and they cost only 33 cents each. Very little spruce and no chestnut or white pine were used in the construction of electric roads. Over [illegible] cypress ties were imported at an average cost of 40 cents each. This is the first report of cypress ties being used for electric roads.

The average cost of ties used in 1910 by electric roads was 41 cents, as compared with 47 cents in 1909. This is due largely to the decrease of 2 cents per tie in the cost of cedar ties and 12 cents in the cost of Douglas fir ties. It is an interesting fact that, although the average tie used by electric roads is smaller than that used by steam roads, the price paid for it is generally greater, viz., 3 cents per tie more in 1910. This is due not only to the disadvantages incident to contracts for smaller quantities of material, but also to the fact that the electric roads are more likely to purchase ties at points where the price includes railway transportation charges. This is shown by the electric roads paying not less than 37 cents for their ties, while many used by the steam roads were bought for 27 cents per tie.

◆

POWER FACTOR, ITS INFLUENCE AND VALUE.*

By D. H. Ross.†

Considerable time has been devoted to the study of load factor and its importance and the improvements this study has brought about have been very beneficial to central stations. But, little attention has been paid to the importance of high power factor and the necessity of including it as a basis of rates which will be fair not only to the operating company, but to the many classes of consumers as well.

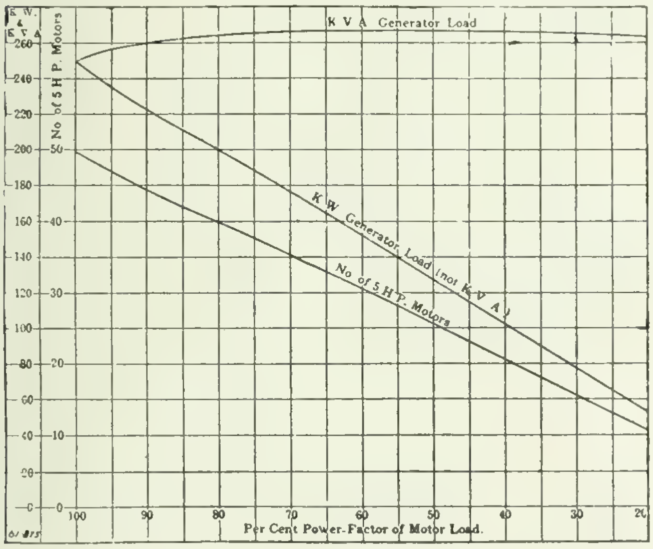

Fig. 1.—Effect of Power Factor on Generator Capacity.

The recent invention, however, of unity power factor motors has turned the attention of the operating companies to the possibilities of saving in cost of service, reduction in over-head charges, etc., to be derived by improving the power factor of their systems. A careful analysis of this subject by the engineering or cost departments of a company will convince the management of the necessity of constant improvement in this respect.

Consider that to supply a given kilowatt load at a low power factor involves:

(1) Unnecessarily large, then hence, expensive generating machines, which are rated according to their current capacity.

(2) Similar expense in generating station, transforming and switching equipment.

(3) Large increase of transmission line, copper cost and distributing transformers.

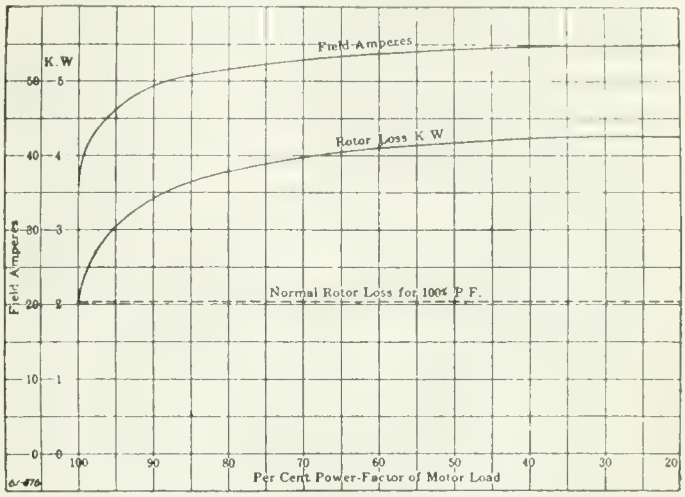

Fig. 2.—Effect of Power Factor on Field Current and Rotor Loss.

(4) Increased core loss in transformers.

(5) Poor regulation of generators on low power factor.

(6) Underloaded prime movers, hence unnecessary capacity and decreased efficiency in their operation at low loads.

(7) Increased maintenance charges due to size and, in many cases, number of units of transformers, switch gear and transmission.

The actual reduction in generator capacity as the power factor is reduced is shown in Figure 1. The lower curve shows the number of 5 h.p. motors which may be operated from a generator of 250 k.v.a. capacity at the different power factors. You will note that at 100 per cent. power factor the generator will drive 50 five h.p. motors, but at 50 per cent. power factor 25 motors only may be carried on the generator and transmission system. Note also that the generator load has increased from 250 to 270 k.v.a., due to the effect of poorer regulation at low power factor.

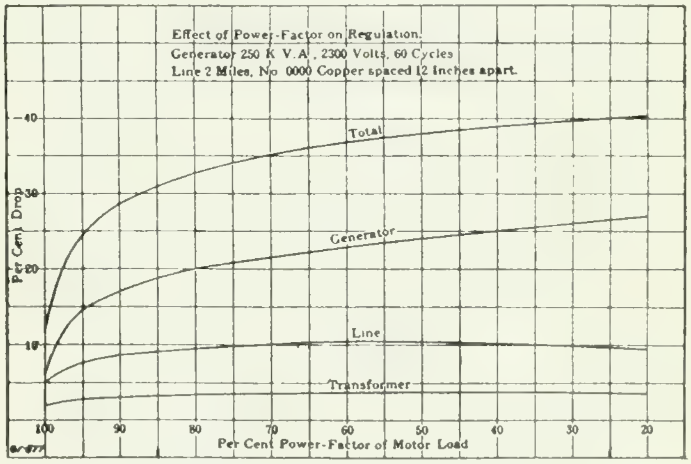

Fig. 3.—Effect of Power Factor on Regulation.

Referring to Figure 2 you will find that not only does the actual productive load to be carried decrease with low power factor, but in itself causes a decrease in efficiency of the generating station, as the field loss is greater owing to the increased excitation, and the exciter sets are either overloaded or larger than is necessary, besides adding to the total loss.

---

* Paper presented at the twenty-second annual convention of the Canadian Electrical Association, Ottawa, June 19-21, 1912.

† Of Wagner Electric Mfg. Co., of Canada.

Figure 3 clearly shows the serious effect of power factor on the regulation, and it is interesting to note that while the slightest increase in power factor is highly desirable, it becomes increasingly important as unity is approached.

From these considerations it is evident that power factor and costs of service are very intimately related, the cost depending almost proportionately one on the other in a water power development and also in a steam plant, except for the extra cost of coal. Should not, therefore, all rate schedules contain a power factor clause which would require the customer with the low power factor to pay for the increased losses and investments as previously listed? The customer when he finds it to his advantage will install high power factor apparatus, and will pay an equitable amount for the power he receives. This state of affairs has been made possible by the production of a unity power factor motor.

This motor, which has been recently placed on the market by a well known manufacturing firm, is unique, and marks a radical step forward in the design of single phase motors.

Note Figure 4, showing the normal running curves of the motor. The power factor is most interesting. You will note that running idle, the motor draws a leading current of 30 per cent., which falls off rapidly as the load comes on, and is practically unity from half load to load and a half. In cases where it is desired, this motor can be connected over compensated, i.e., it will give a leading current of 5 per cent. to 10 per cent. at full load, and 40 per cent. to 50 per cent. running idle. Note also that the slip is practically negligible, being about 1½ per cent. at full load.

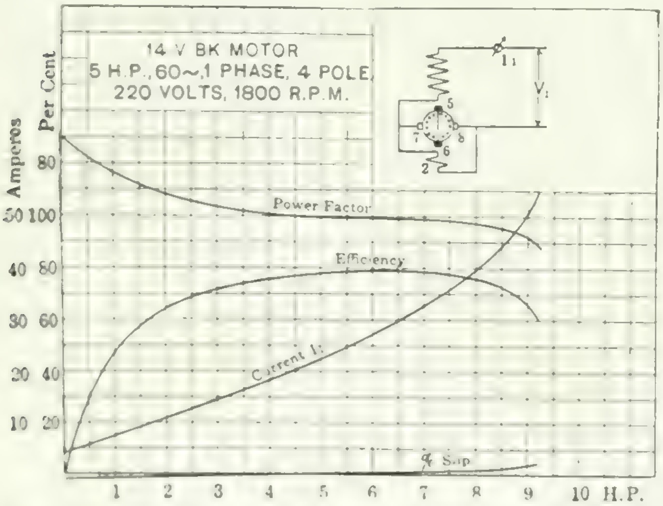

Fig. 4.—Type B K Wagner Motor Normal Running Curves.

Figure 5 shows the comparison of speed torque curves of the Arnold and unity power factor motors. It is interesting to note that while the torque at the instant of starting [illegible] start, which the Arnold type motor will not do, owing to the torque falling off rapidly as the speed increases. [illegible] This motor is not radically different in operation from the [illegible]

[illegible]

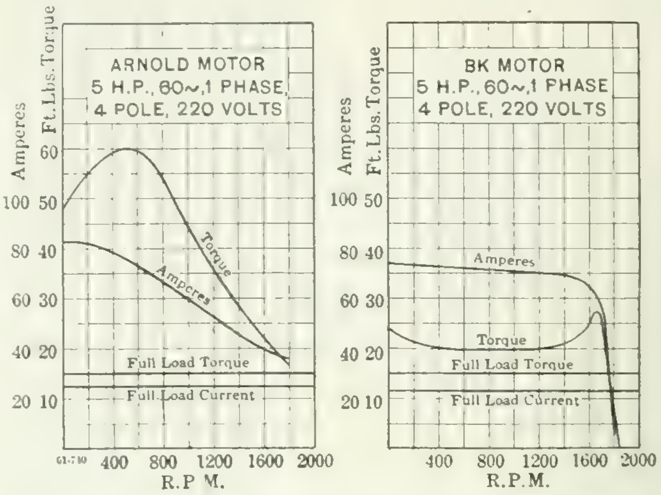

Fig. 5.—Comparison of Torque Characteristic Curves of Arnold and Unity Power Factor Motors.

portance of these unity power factor motors will be inestimable as a means not only of saving to the central station in installation, maintenance, metering, etc., over a polyphase installation, but maintaining a system of practically unity power factor.

This paper is not attempted as a treatise on this subject, rather as a rough outline which may serve to promote valuable discussion among the members interested in central station economies.

CALGARY'S NEW UNIVERSITY.

Mr. Dunnington Grubb, the Toronto landscape artist who is associated with Mr. Mawson, the English landscape artist in several projects, was recently in Calgary with landscape sketches of the grounds and buildings of Calgary University which provide for the building which, when completed, will provide accommodation for students for many years to come when the population of the province has more than doubled, and which when completed will cost $15,000,000.

Two magnificent sketches prepared by Mr. Grubb show the main building of the university to be in a line with Eighth Avenue. The arts block, library museum, dormitories and the residence of the professors is also provided for in the plans and are laid out with the greatest of care and skill both from utilization and artistic viewpoints. Work on the coonstruction of the building will be commenced as soon as the plans are approved by the building committee. This building alone will cost $5,000,000.

The university will have a campus of 30 or 40 acres and an athletic field of seven or eight acres on which a stadium in amphitheatre shape will be placed with capacity for several thousand spectators.

Several attractive drives and walks have been arranged for in the plans and they also call for handsome flower beds and other plots for outdoor ornamentation.

CANADIAN INDUSTRIAL EXHIBITION, WINNIPEG.

A visit should be paid to the Canadian Industrial Exhibition at Winnipeg, one of the finest exhibitions on the continent. The prospects are for a better show than even that of last year, which is strong testimony to its merits and attractions. The exhibition will be in full swing until next Saturday.

THE FACULTY OF APPLIED SCIENCE AND ENGINEERING OF THE UNIVERSITY OF TORONTO.

The growth of engineering education has been tremendous during the last twenty years, and particularly in the last ten years. From departments of comparative insignificance in University curricula the faculties of engineering have become so important that they are now taking first place in the minds of university authorities. The Faculty of Applied Science and Engineering of the University of Toronto very well exemplifies this growth and change of sentiment. In a recent article by Prof. H. E. T. Haultain, of that Faculty, on "Mining and the University," a résumé of the history of the Faculty was given. It affords most interesting reading. Perhaps the most striking feature of the article is the emphasis laid on the work done by the present Dean of the Faculty in developing the different courses which are now the several departments of the Faculty's work.

Dean Galbraith was appointed Professor of Engineering in 1878, and for the first few years of the School's existence he did all the engineering teaching. It is a noteworthy fact that the main features of the course, as then laid down, still control the policy of the Faculty. As Professor of Engineering, Dean Galbraith held that the practice of engineering should be learned in the field, and that the course in the School should consist of a groundwork of pure mathematics, and a broad training in principles, followed by illustrations of the applications of the principles. He believed, and has consistently followed his belief in directing the trend of development, that everything should be made subservient to the idea of the application of principles. His oft-reiterated statement: "We do not make engineers; we prepare them to become engineers," is worthy of record.

The consistent growth and the wonderful success of this department of the work of the University of Toronto is largely due to the man, John Galbraith. Too much credit cannot be given him when one knows of the early struggles of the School before it became an integral part of the University. On the placing of the School of Practical Science under the University of Toronto, Professor Galbraith was appointed Dean. Of the men who have been associated with engineering education in Canada, he is, without doubt, the outstanding figure. He ranks as an engineer, as he does as an academician and educator. The report of the Royal Commission on the Quebec Bridge stands to the credit of Mr. Holgate, Mr. Kerry and Dean Galbraith. With such a record of achievement, it is hard to understand the attitude of the Board of Governors of the University of Toronto as shown in their last report. There we see that several others of the University staff are getting salaries far larger than that allotted to the Dean. Aside altogether from his personal record, the position of head of one of the most important faculties of the University demands recognition at least equivalent to the other members of the University staff. When this question was brought to the attention of the Board of Governors recently, they stated that the present financial condition of the University would not allow the matter to be adjusted. It is hard to understand their position in this matter when it is remembered that on the first of June last the Professor of Biology was allowed to retire, in full health, five years before his regular time, and was allotted an annual allowance of nearly three-quarters of the Dean's present salary. Certainly in giving this $14,000 the University did not feel in very straitened financial circumstances.

UNITED STATES RAILROADS IN CANADA

A despatch from New York states that Newman Erb, president of the Minneapolis and St. Louis Railroad, has left for a trip, during which he expects to complete the incorporation of a new company to build branches to the Canadian border. The southern terminal of the new line is to be Watertown, S.D. Plans for these extensions, which, it is said, will eventually mean a new Canada-to-the-Gulf line, by a connection with the Missouri, Kansas and Texas, were interrupted some time ago by the sudden death of Edwin Hawley. This is another reminder of the growing and natural tendency of United States railroads to extend to Canada, and vice versa. The United States railways have 1,485 miles of track in Canada, while the Canadian railways have no less than 7,197 miles of track in the United States, divided as follows:—

	Miles.	
Grand Trunk Railway—		
Grand Trunk Western Railway	336	
Detroit, Grand Haven and Milwaukee Railway	191	
Toledo, Saginaw and Muskegon Railway	116	
Cincinnati, Saginaw and Mackinaw Railway	53	
Pontiac, Oxford and Northern Railway	100	
Central Vermont Railway	612	
Island Pond to Portland	150	
Detroit and Toledo Shore Line Railway	78	
		1,636
Canadian Northern Railway—		
D.R.L. and W. (Fort Frances to Duluth)	170	
		170
Canadian Pacific Railway—		
D.S.S. and A. System	614	
Soo System	4,295	
Spokane International	140	
Sumas to Seattle	125	
Megantic to Vanceboro (Maine)	217	
		5,391
Total		7,197

The Grand Trunk had a big fight to obtain admission into New England, but its efforts were successful. The main purpose of extending that road into the rich traffic territory of New England is, according to the Grand Trunk's own contentions, to balance their business between the Eastern and Western States. The Grand Trunk's double track main line lies across Canada like an arm, the elbow at Montreal, the forearm across Ontario, the hand upon five fertile and productive States, with Chicago, the great traffic centre, in its palm. The fingers of this hand are the feeders, which will bring through this American gateway the traffic of the West, the North-West, and the South-West. The trend of this traffic, eliminating the Grand Trunk, is to the Atlantic seaboard. With the system, the traffic organization, and friendly connections at Chicago, the Grand Trunk gathers a vast volume of the freight and carries it eastward across Canada. When they do this they contribute not only to the earnings of the Grand Trunk, but to the prosperity of the Dominion.

The interchange of traffic in the two countries recalls the suggestion of the late Judge Mabee, when chairman of the Dominion Railway Board that an International Railway Board should be formed. The Canadian Minister of Railways has correspondence with the United States government on this matter. It is [illegible] that importers on both sides of the line are often compelled to pay two local rates, one to the border from the place of shipment and the other from that point to destination. Under existing conditions neither the Canadian Board nor the Interstate Commerce Commission has power to make a through rate, and it was suggested that an International Board be formed, made up of members from the two boards mentioned, and that this international body be given power to make through rates. A draft arrangement was discussed on both sides of the border. To this proposed agreement the railway companies took exception. There are prospects, however, that the consideration of the matter will be continued by the two governments concerned.

◆

STEEL INDUSTRY FOR BRITISH COLUMBIA

The opening of the Panama Canal will develop the coal industry in British Columbia. That in turn may draw greater attention to the iron deposits in the province, and later mean the establishment of iron and steel works on our Pacific coast. Important bodies of high-class magnetite are known to exist, the most familiar being Texada Island, Bugaboo Creek, on the west coast of Vancouver Island; at Qwinsam, near Campbell River, and on Louise Island, of the Queen Charlotte group. Of these, Texada Island is considered the most important, as the quality is high grade and as the quantity is large. Its situation is such that with moderate equipment it could deliver ore on ship at tide water at a very low figure, possibly not to exceed 70 cents per ton. At Quinsam a crew has been kept on development all winter. Little has been done on the other properties, but mining engineers had spoken highly of them, both with respect to quality and quantity.

In the opinion of Mr. R. R. Hedley, one of the foremost mining experts in Canada, and a particular authority on British Columbia, the building of a plant on our Pacific Coast to manufacture iron and steel is not only justified, but required. There is a large increase in the use of structural steel and reinforced concrete. Railway construction and maintenance and the general rapid progress of the country are also good reasons for the construction of such a plant. During the last quarter of a century the Union Iron Works of San Francisco have made the best of pig iron at Irondale, Wash., from Texada ores. More recently the Western Steel Corporation, with modern plant at the same place, made pig iron, using Fernie coke costing $10 per ton. This was intended as the nucleus of structural iron and steel works, but it was found that Chinese pig iron could be laid down at a cost of $10 per ton, and smelting of local ore was abandoned. With equipment none too good from the economy point of view, the costs were reasonable, but the enterprise was not properly financed, and operations ceased. Given a good quality of metallurgical coke costing not more than $5 per ton, which it is reasonable to expect in the near future, there is no reason why British Columbia pig iron should not take the place of Chinese, and a profitable industry be established on our own side of the line. Cheap power is also available.

◆

EDITORIAL COMMENT.

This week there will be found the first instalment of a series of four articles on the high-tension transmission system of the Hydro-Electric Power Commission of Ontario. In the light of the recent very successful operation of the system as compared with private companies, this series will be of particular interest to our readers.

In a recent issue of the Yorkton "Enterprise," of Yorkton, Sask., a firm of real estate brokers state in an advertisement that they handle real estate collections and civil engineering, and are financial agents. They add that they have numerous pieces of valuable "inside" and "outside" property, suitable for business houses, etc. It is hard to see in what particular way this firm are interested in carrying on the profession of civil engineering. Some users of the term, like the above, do much towards detracting from the dignity and standing of the profession. There is at present, however, no means of taking the matter up in the courts, and this is one argument at least for making the profession a closed one. At present the term is a most convenient one for those who wish to use it.

◆

LETTERS TO THE EDITOR.

A WARNING TO ALL CIVIL ENGINEERS.

Sir,—The following is a word of warning to all civil engineers when being engaged by a certain class of corporations that they should be most careful to have a note in writing of the amount of their salaries, because some engineers have appointed assistants and then gone back on their word and thought to settle the matter of a salary by a reduction of 20% of the amount previously arranged. When engineers cannot trust each other there is little confidence of the public in such representatives of the engineering profession. The writer has seen three-quarters of this world, and except in the Dominion of Canada, he has never encountered such underhand practice as outlined above, and has found that the members of the profession have always upheld the standard of straight and clean dealing amongst themselves and in their dealing with public affairs.

DISGUSTED A.M.I.C.E.

* * * *

ENGLISH ENGINEERS FOR CANADA.

Sir,—I should like, as an engineer living in England, to put before your readers the case of the hundreds, probably thousands, of English engineers of all kinds who are anxious to settle in Canada, but are unable to do so because they can hear of no jobs there. We are told in England that if a man wants work in Canada he must go there to look for it and take the first job that comes along.

I, myself, have written from time to time to several large firms, railway companies and consulting engineers in Canada, stating my qualifications and asking for the promise of a few months' trial in any fairly paid engineering capacity; a not unreasonable request, as the risk is practically all on my side. I received courteous replies in, I believe, every case. One railway company offered me a job, as they kindly said, to go on with until I could find something better, but at half the salary I was getting. Another firm said they could make use of me, but did not commit themselves to anything more definite. The other people all regretted that they had no vacancies, but at the same time several of them advised me to come to Canada, as they had no doubt I should get a good post there.

Now, this is well enough, as far as it goes, but it does not go far enough. It would go far enough for a man who could absolutely find no work in England, or for a single young fellow who had enough money to keep himself for some months in Canada while he was looking for a job, but the men I have in mind are those who are already in berths, steady, hard-working fellows, ambitious to get on, but seeing very little prospect before them in England and, therefore, turning their thoughts to other parts of the Empire.

Many of these men have a wife and young family to keep on a small salary and have no private means of their own and no rich relations to help them. However much such a man might wish to try his fortune elsewhere he feels that he is not justified in doing so merely on speculation. He has no money to leave with his family in England while he goes to Canada, and he dare not take them with him unless he has other work to go to at once.

This question does not affect the single man, but as they feel their feet on the first rungs of the ladder they are not willing to give up what they have unless to take something better. They are quite ready to go abroad. and they do go abroad, even to the most dangerous and unhealthy parts of the world, but they want something to go to.

The case of the engineer already in a good position in England, but who wishes to settle in Canada for various reasons, is rather different, although it still turns on the same point.

Take the case of a works manager getting £500 or £600 a year, a good salary from an English engineer's point of view. Such a man may be from 35 to 45 years of age and he probably has a family to whom he is giving the best education he can afford, so that he is not able to save much out of his salary. He may be ambitious and feel that Canada will give him more scope than England; he may think that his children will have better chances there; he may be an imperialist, as very many of us are, and wish to do his little share in building up the newer parts of the Empire, or he may have various other reasons for wishing to earn his living in the overseas Dominions.

He may be able to find enough money to take his family with him to Canada and to keep them there for six months or a year, but unless he has a definite position to go to he has much to make him hesitate. In the first place, his wife will probably object strongly, as the ladies in these cases generally have a firm belief in the old adage that "a bird in the hand is worth two in the bush."

He knows that he has worked hard to attain and to keep his present position, and he also knows that there are hundreds of men ready to take that position, many of them fully as well qualified in every way as he is, and if he gives his job up he may find it impossible to obtain another similar one in England, should he be unsuccessful in finding a suitable post abroad. Such a man would be naturally unwilling to take a less important job in Canada than he had filled in England.

The above are the reasons, I believe, which prevent the best engineers from going to Canada, except to take up positions which have already been offered them. There are really only two main reasons: want of money to go out on spec., and unwillingness to throw up a job until another one is secured.

It is possibly owing to the fact that not enough of the best classes of English engineers have been attracted there that American engineering practice is general in Canada. This seems a pity, as I am Britisher enough to believe that our engineers are at least as good as the Americans. I have no quarrel with American engineers; they talk too much perhaps, and they do not show up to advantage in England, but it cannot be denied that as a body they are quicker and more alert than English engineers, which, however, I believe is due more to the climate of America and to the fact of its being a new country than to anything else.

When we consider that the British Empire embraces a fifth of the entire surface of the globe and more than a fifth of its inhabitants, and that this result has been brought about largely by the help of British engineers, we must admit that they are not quite played out yet.

But, while engineering in Canada is advancing and will advance by leaps and bounds, the engineering trade in England is practically stationary, and will probably decrease in volume in the future owing to the much more severe European competition, so that many of our engineers will be obliged to transfer their services to other parts of the Empire.

I believe that it would be a benefit all round if some kind of exchange or employment bureau could be arranged for English engineers wishing to settle in Canada, and there are various ways by which this might be done.

One way would be through the engineering societies of the two countries. There are, roughly, 15,000 members of all grades in the three English institutions of civil, mechanical and electrical engineers, and as these societies already do something in the way of bringing their members into touch with employers or employees they would no doubt be very willing to work in conjunction with the Canadian Society of Civil Engineers to provide Canadian firms with suitable engineers from England. The English institutions, for instance, might collect the names of all of their members who wished for work in Canada, together with full particulars of each man's career and experience and the salary he desired, and these lists would be forwarded, say, twice a month to the headquarters of the Canadian society, where they would be on view and copies posted to any employer who desired one. The employer could then communicate direct with the man he thought most likely to suit him, making a definite offer for a three months' trial, and by cabling his offer he might have his man in two weeks' time.

This plan would, I believe, work well and the Canadian employer would have some guarantee as to the character and professional abilities of the men whose names were put before him, but there are great numbers of good engineers who do not belong to any of the institutions mentioned above, and who would be left out of such a plan.

Perhaps a better arrangement would be to deal with the question through the Canadian Government Emigration Department. This department, through its chief London office, might invite particulars as to experience, etc., from any English engineers desiring to settle in Canada, by advertising from time to time in some of the English technical and daily papers, and by sending circulars to all the engineering societies. The names and particulars sent in would be tabulated, numbered, and sent to Canada, where the lists would be distributed in various centres, where employers could see them or write for copies.

The essence of the scheme would be that each party took a certain amount of risk. The man from England would pay his own passage to whatever part of Canada he was going to take the risk of suiting his employer and being able to hold his position, while the employer guaranteed to give him a three months trial at a stated salary and to take the risk of him being suitable or otherwise. The risk to the Canadian employer would not be great, as the English engineer already in a berth would not be likely to pay his passage to Canada and probably take his family out on the [illegible] could be specified that the employer had power to break the contract by reason of [illegible]

[illegible] to Canada would [illegible] but most employers would [illegible] the [illegible] the Canadian employer could cable to London [illegible] address, the number of the man he wanted and the salary he offered, and the London office could communicate with the engineer, who would make his arrangements to sail as soon as possible, or reply at once if he was unable, through any reason, to take the post offered.

I believe that some such scheme as outlined above would be practicable. It would be a boon to a great many engineers in England who are struggling along with very slight prospects of bettering their positions in this country, and it would provide Canada with some very useful citizens.

R. D. SUMMERFIELD,
11 School Road, Moseley, Birmingham.

A MOVING-PLATFORM SUBWAY LINE.

A moving-platform subway line has been laid out in New York City by the Public Service Commission. It is to be a crosstown line on 34th St., from Second Ave. to Ninth Ave., a distance about one mile east and west. The end portions are to form loops, the easterly loop extending through 34th St., Second Ave., 35th St. and Third Ave. to the corner of 34th St. and Third Ave., while the westerly loop, beginning at a point in 34th St. between Eighth and Ninth Aves. passes under 34th St., Ninth Ave. and private property to the point of beginning. The route has been laid out as a result of the proposals of the Continuous Transit Securities Co. (M. E. Schmidt, pres.), which company has been promoting moving-platform proposals in New York City for a number of years past, hitherto without success. In order to provide against the risk of failure of the moving-platform method of operation, the Public Service Commission's resolution laying out the route provides that it may be operated "either by moving-platforms or by separate cars or trains, or by any other device or means in the construction of which stationary means for guiding a conveyance in a definite path and means for propelling such conveyance are necessary elements." In this way the resolution will also cover operation by ordinary rapid-transit trains if this is considered necessary after trial of the moving-platform method.

The proposed moving-platform line will pass through one of the busiest parts of the city, crossing seven north-and-south rapid transit lines (four elevated lines, three subway lines) and ten north-south street-car lines. At Broadway it will be within one-half block of the present northern terminus of the Hudson tunnel system, which communicates with Hoboken and Jersey City and indirectly with the lower part of New York City. At Seventh Ave. it will be within one block of the Pennsylvania R.R. station. The 34th St. district at present contains half a dozen large department stores, and shopping business has in recent years concentrated in this region very strongly. The present theatre district extends north from 34th St., and the principal hotels of the city are grouped along Broadway in this neighborhood.

A NEW ENGINEERING FIRM.

Mr. P. W. Sothmann, recently chief engineer of the Ontario Hydro-Electric Power Commission, has opened a consulting office in the Kent Building, Toronto. The firm name is P. W. Sothmann and Co., and the organization includes Mr. P. W. Sothmann, Mr. J. A. Brundige and Mr. F. P. [illegible]. The field covered by the new firm will be hydro-electric development, high tension power transmission and other work connected with the generation and distribution of electrical energy.

IRRIGATION PROJECTS OF THE CANADIAN PACIFIC RAILWAY COMPANY IN ALBERTA.

By A. S. Dawson.*

(Continued from last week.)

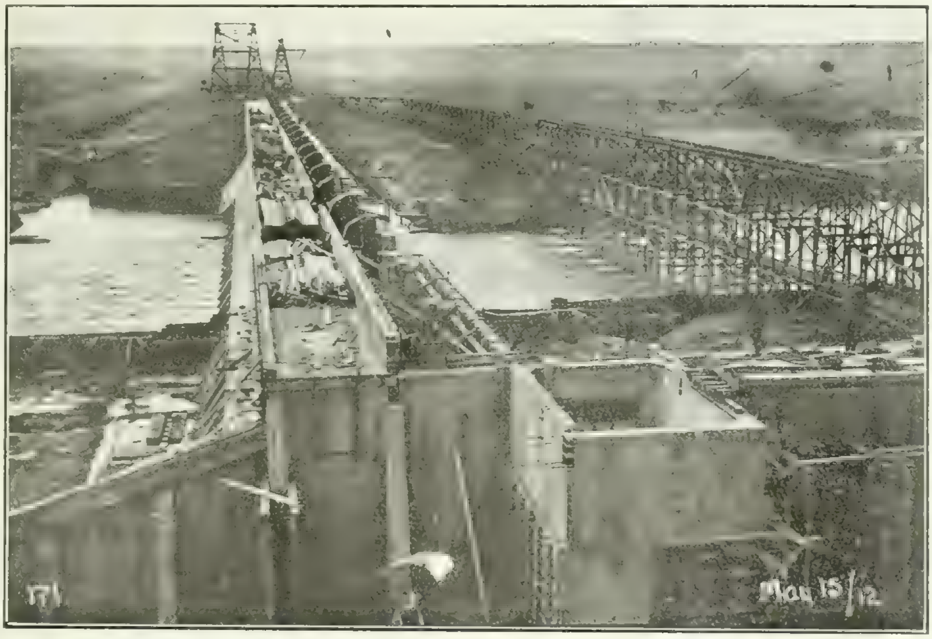
The abutments connecting the spillway with the earth dam are in the form of reinforced concrete retaining walls of the "counterfort" type, with a view of cutting off all possibility of leakage at this point. Provision has also been made for a road bridge on top of the structure.

The gates will be operated by a small power plant consisting of vertical turbines with direct connected generators installed inside the dam for this purpose, as well as for lighting and the operation of other headgates at the end of the main canal about five miles distant.

The canal headgates will form an integral part of the structure at its easterly end, and will consist of five openings each of 20 feet, controlled by "Stoney" sluices. These gates will control the discharge through a main canal of 90 feet bed width, carrying 11 feet of water, with 1 to 1 slopes, on a grade of .016 per cent. This canal is designed to discharge 3,800 cubic feet per second, and has a summit cut of 55 feet at about Station 10.

The contract for the spillway structure was let on October 1st, 1910, and work immediately started, it being anticipated that it will be completed within 18 months from that date.

The earthen embankment referred to is part of a very large contract awarded in June, 1910, which includes the handling of about 20 million cubic yards of excavation in this sec- of the Block.



Ambursen Type Dam on Bow River, near Bassano, Alta. Headworks of Eastern Section, C. P. Railway Irrigation Block, Alta.

At a point about five miles from the intake, an earth dam 1,280 feet in length, 35 feet maximum height, containing 80,000 cubic yards, was built across the valley, thus forming a tail pool into which the main canal will discharge. This dam has a top width of 12 feet, six feet above high water; has 2 to 1 slopes on the rear face and 3 to 1 on the wetted slope. Its face is paved with heavy rip-rap well bedded in gravel.

From this point two canals ahead a north and east branch. The north branch with its distributaries will water about 90,000 acres, its dimensions being 29 feet bed width, carrying 6½ feet of water, with 2 to 1 slopes, on a grade of .03 per cent. After crossing the railway line about one mile east of Bassano, its location follows the west flank of a deep valley known as Crawling Valley At a point about eight miles from its intake it drops 18 feet and crosses the valley by about 1,700 feet of flume, and runs northerly, gradually reducing in size until it reaches the Red Deer slope.

The east branch, like the north branch, heads out in the tail pool of the main canal, its size at the outlet being 68 feet bed width, carrying 9.3 feet of water, with 2 to 1 slopes, on a grade of .015 per cent. Near Lathem the first branch takes off, dropping 25 feet to cross the railway and water an area of about 107,000 acres between the Mat-zl-win and the One Tree Creeks. This branch is known as the Spring Hill Canal and is about 35 feet bed width, carrying 7 feet of water, with 2 to 1 slopes, on a grade of .025 per cent.

The east branch continues south-easterly along the northerly flank of the watershed as a 45.3′ by 7.8′ canal with a grade of .02 per cent., reaching the height of land at the head of Antelope Creek, which is crossed by a flume 2,200 feet long with a maximum height of 22 feet. At this point it again forks, the south-easterly branch being known as the Bow Slope Canal, which is about 17 feet bed width, carrying 5 feet of water; and will serve all the land on the Bow River slope of the divide and lying west of the Rolling hills, amounting to about 42,000 acres.

At Cassils a smaller canal to cross the railway is taken off, to serve about 12,500 acres; and just south of Brooks the east branch discharges its waters with a drop of about 17 feet into Lake Newell reservoir, which will be formed in a depression in the Little Rolling Hills, by the construction of a number of earth dams, the largest of which will be about 2,000 feet long and 30 feet in height. This reservoir will be about 9 miles long and 4½ miles wide, and its storage capacity will be about 180,000 acre feet. It will be filled each season after the close of the irrigation period, and was the means of materially reducing the cost per acre of the project as a whole.

A tract of about 50,000 acres south of the reservoir will be served by a canal heading out at the south end. This will be known as the Rolling Hills Canal, of about 19 feet bed width, carrying 5½ feet of water, on a grade of .02 per cent.

The outlet from the north end of the reservoir will serve about 118,000 acres known as the Bantry system, and its dimensions are 44 feet bed width, carrying 7.7 feet of water, on a grade of .01 per cent, and about five miles in length. At its easterly end it will discharge into a reinforced concrete flume 10,500 feet in length with a maximum height of 54 feet and a sectional area of 129 square feet.

---

*Chief Engineer, Department of Natural Resources, Canadian Pacific Railway Co.

Considerations of storage values fixed the elevation of both ends of this structure, and under these conditions the type of crossing which gave the highest velocity for a given fixed friction head was imperative.

Numerous preliminary studies were made for the purpose of comparative estimates of cost, with the result that a somewhat unique design is likely to be adopted. The actual channel is of the suspended type commonly used in steel flumes. The exact section proposed is the elastic curve or hydrostatic catenary. For the purpose of a flume this curve has the advantage that it is the equilibrium polygon for a liquid filling it to the chord of the arc; the tension is everywhere the same; and there is neither moment nor shear at any point. When the structure runs partially full, there are both moment and shear, and these are the factors which fixed the thickness of the shell. The substructure of the flume will vary with the head, and it is probable that multi-arched design will be adopted, with spans varying from 30 to 100 feet. For the depressed portion under the railway line it is intended, as previously intimated, to use a reinforced concrete siphon; and in order to save excavation and provide means of measuring the discharge it is proposed to form a Venturi meter with a throat section of about 6 feet. The structure as a whole will probably contain about 25,000 cubic yards of concrete and upwards of two million pounds of reinforcing steel.

This flume will carry the water over a broad divide in the water-shed with [illegible] point about three miles south-east of Brooks, and will serve all the country east of that point.

At the easterly end of the flume the canal section [illegible] width, carrying 7.7 feet of water, [illegible] .01 per cent., and in the north-east quarter of section 23, township 18, range 14 it splits, one branch of 37½ feet bed width, carrying 7.2 feet of water, on a grade of .01 per cent., running north; and another branch of about 16 feet bed width, carrying 5 feet of water, [illegible] the railway line.

In [illegible] the northerly branch [illegible] feet bed width, carrying 5½ feet of water, on grades of .01 per cent., one [illegible]

The [illegible] mileage of canals and ditches [illegible] this portion of the Block is as follows:—

	Miles.
Main canal	5
[illegible]	[illegible]
[illegible]	[illegible]
Total	[illegible]

[illegible]

[illegible]

The different cross sections of canals and ditches are modified to suit conditions, such as discharge, available grade, nature of soil, and transverse slope of the country. On ditches 2½′ by 1′ to 3½′ by 2′, 1 to 1 slopes are used, and on ditches 4′ by 2′ to 4½′ by 3′, 1½ to 1 slopes are standard, with banks 3 feet wide on top and one foot above water level. On small ditches no dependence is placed on banks as part of the canal prism unless the grade is one foot below the under side of the sod, or about 1½′ cut on an average. On larger ditches on level ground the area of the water prism is generally about the cube of the depth; the banks being half the depth of water level, with a maximum of 3 feet; and a width equal to the depth of water on the upper side, and 12 feet on the lower side, where a roadway is required. Where the depth of water is over about 5 feet, 2 to 1 slopes are standard, although this is changed to 1½ to 1 where extreme cross slope exists. Where the depth of water is less than 5 feet, 1½ to 1 slopes are standard under ordinary conditions. Endeavors are made to balance cut and fill, with an allowance of about 15 per cent. for shrinkage, unless it happens that shorter locations with heavy cutting through a ridge would result in a reduction in quantities.

The grades are so selected as to give a uniform velocity of about 2½ feet per second, and not to exceed 3 feet per second; consideration being given to the character of the soil, and the depth of water in the ditch.

Where the slope of the country is so great that the velocity would be too high if the canal were given a bed slope to correspond therewith, the excess fall is concentrated by vertical drops; and where such drops occur too close to one another for safety or economy, a short section of flume or lined channel is employed for the purpose of overcoming the excessive grade. Losses by seepage and evaporation are allowed for as follows:—

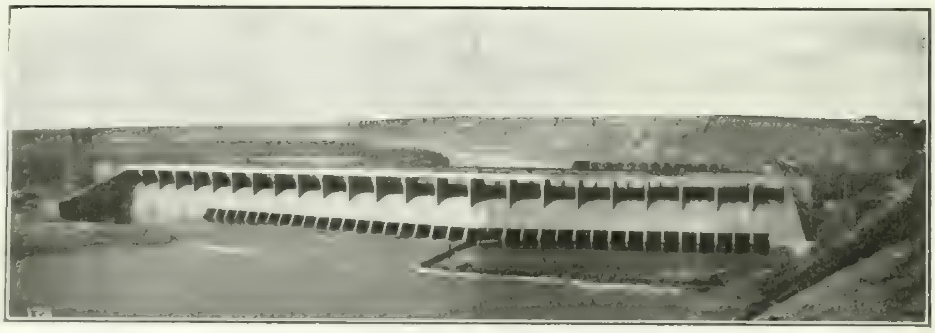


Fig. 9.—Ambursen Type Dam on Bow River, near Bassano, Alta., Eastern Section C.P. Railway, Irrigation Block, Alta.

In preliminary projection:

		Per Mile.
Canals	2 to 100 sec. feet	1
"	100 to 500 "	.5
"	500 to 1000	.25%
"	1000 and over	.10%

For final projection and design the following formula is used:

$$P = C\ W\ d$$

where P = loss in second feet per mile of canal.
W = the width at full supply level.
d = the depth of water.
C = a constant [illegible] for sand
[illegible] for gravel and sandy soil.
[illegible] for average earth.
.0150 for clay
[illegible] for dense hard clay

Curvature is carefully considered and on the larger canals curves are regularly run in with transit and chain, the radius allowed on the larger secondary and branch canals being between [illegible] and [illegible] times the depth of water. On smaller distributing ditches a radius of [illegible] to 8 times the depth of water, with a minimum of about 10 feet, is aimed at. As far as possible the land lines are adhered to in laying out the distribution system.

At each point where water is divided by a branch gate, an alternative path is provided to carry off tail water to some drainage channel, the capacity of these tail channels bearing a constant proportionate relation to that of the various irrigation ditches above them. In no case is this less than 2 second feet, and otherwise is 25 per cent. of the capacity of the canal or ditch just above. These tails are located on the land lines as far as possible; otherwise they are made to reach the drainage channels by the shortest possible route.

Cross drainage is provided for in three ways: (1) it is taken under the canal; (2) if small in extent of catchment area, it is taken into the canal system by an inlet; (3) it is carried over the canal. The type of crossing adopted depends to a large extent on the importance of the drainage line; on the character of its channel; and to some extent on the size of the canal. No definite rules can be laid down to meet all cases, but as a rule the cross drainage is handled in the order above referred to, with due consideration of cost. The material chiefly used in connection with the smaller under crossings has been corrugated metal culverts, up to 36 inches in diameter, manufactured from both Ingot and Toncan metal. For larger structures reinforced concrete pipe and arch culverts will be used.

Flooded areas are avoided by the use of double fills or levees, combined with means of taking care of the cross drainage as above referred to.

Spillway or escape channels, with the necessary structures on the canal system, are provided at frequent intervals, averaging about 6 miles where possible, on all secondary and branch canals, their capacity being at least 10 per cent. and not exceeding 25 per cent. of the canal in which they head.

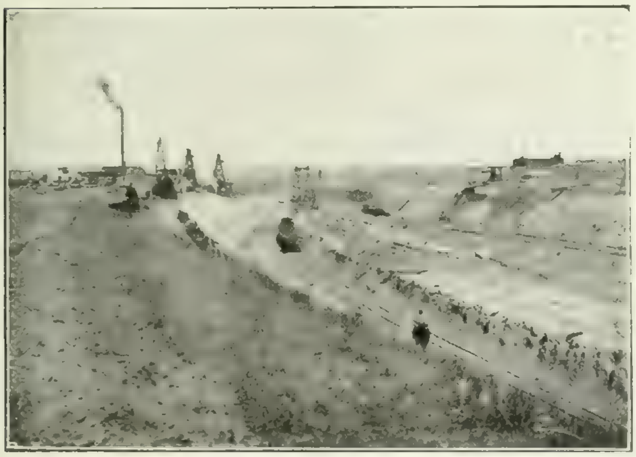

Fig. 10.—Excavation, Main Canal, Eastern Section of Irrigation Block.

Overhaul is calculated by the well-known methods of Mass Curve, the limit of free haul being 100 feet parallel to the canal axis. In case of borrow pits not on the ordinary cross section, the length of haul is measured in a straight line between the centres of gravity of cut and fill.

Necessary waste is used to widen the banks uniformly, and to strengthen the higher fills. Borrowing where necessary is done by (1) deepening the canal; (2) widening it; and (3) both if required. If neither is practicable, borrow pits are made well away from the canal on the high side and so arranged as to drain into the canal. Where side borrow is absolutely necessary, a berm equal to at least the height of the bank is left between the toe of the bank and the edge of the borrow pit.

Embankments are in all cases put up with material from adjacent cuttings or from borrow pits if the former is unsuitable or deficient in quantity. In determining the outer slope, the plane of saturation is considered as sloping from high water level at the rate of 3½ to 1, and this plane is not allowed to intersect the outer slope or to approach the toe nearer than 10 per cent. of the base width. In very high fills where the above requirements lead to excessive material, the slope of saturation is increased by draining the rear or outer half of the embankment, or by constructing the first three feet of the outer third of the bank with sand, gravel or other porous material.

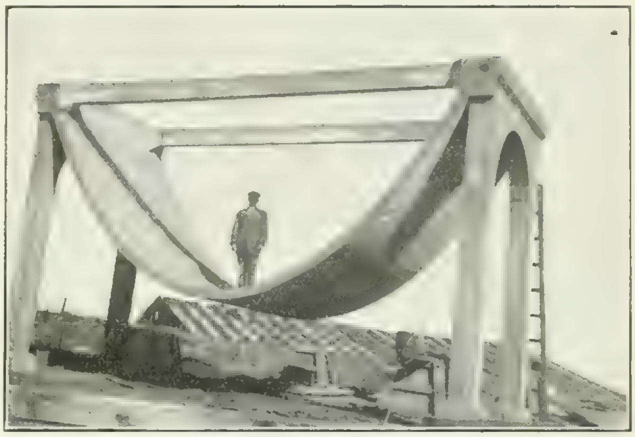

Fig. 11. Test Section, Proposed Aqueduct, 18 Ft. Wide, 9 Ft. Deep, 1,000 Ft. Long. Eastern Section of Irrigation Block.

The under surface of the embankments is bonded when the head against the banks is 2 feet or more, and less than half the top width, providing two furrows and one additional furrow for each extra two feet, with one furrow just inside the upper or wet toe, one under the centre, and the balance, if any, between them. The surface is stripped when the depth against the bank exceeds half its top width; when the cross slope exceeds 1 in 6; in boggy ground; or when the soil exceeds plow depth. The surface is bonded and stripped when the head against the bank exceeds 10 feet; when the surface is hard and dry after stripping; or when the cross slope exceeds 1 in 4. The width of stripping is determined by the plane of saturation above referred to.

This portion of the system is being designed with a view of rotation in supply being adopted, which will result in each individual farmer obtaining a satisfactory head; a fair division of water; and simplification of operating problems. This is a matter which cannot be worked out in detail until the lands are settled, but the system is being designed on the basis of giving parcels of between 80 and 160 acres a supply of two second feet for a period of 96 hours, and parcels smaller than 80 acres a similar flow for 48 hours.

It is the intention that daily records of the receipt and delivery of water and of the outflow through all branches of the system shall be maintained from the beginning; such data being as necessary in irrigation management as is bookkeeping in any commercial institution. The information thus obtained is essential in enforcing proper water economy; in preventing land from being injured; and in keeping farmers from getting into bad habits in using water, which if once acquired, result in reduced crop production, increased cost of operation, and needless annoyance to the management.

World-wide experience in the use of water on cultivated lands under any kind of crops during long periods of years, shows that the duty varies with, (1) the nature of the soil; (2) the age of the soil; (3) the kind of crop; (4) the weather conditions; (5) the slope and condition of the conveying channels of supply; (6) the distance the water is carried in the ditches and channels to the fields; and (7) the experience and skill employed in irrigation. As you are aware, the legal duty in the province of Alberta is fixed by the Irrigation Act as a continuous flow of one cubic foot per second per 150 acres for 153 days between May 1st and September 30th. Measurement of this supply is arranged for by weirs approved of by the Commissioner of Irrigation.

The company has adopted the plan of constructing the complete distribution system so as to deliver water at the boundary of each farm unit of 160 acres or less; as it was considered impracticable to leave to the settlers the building of the smaller ditches, which would have resulted in delays to the work, excessive cost and a retarding of the development of the area, followed by increased difficulties in operation. In constructing the distribution system, 160 acres has been considered the farm unit, although in the western section several colonies have been established on the so-called "ready-made" farms of 80 acres. In the eastern section of the Block about five per cent. of the farm units will be sold as 80-acre farms, in addition to the establishment of a number of colonies on farms averaging from 80 to 120 acres.

The successful outcome of any large irrigation project is only partially solved by good construction; and in some cases the administrative heads of large schemes have failed to realize that the ultimate success of such enterprises cannot be fully brought about without farmers; and that it is their labors which determine the real value of such properties. With this realization, the sale of the lands in this Block warranted the establishment of a very large organization which has extended over all important points in Canada, the United States, Great Britain and parts of Continental Europe; and which has resulted during the past five years in the disposal of over 1,300,000 acres.

Everything that follows in the wake of increased population is an argument in favor of irrigation and the cultivation of small areas; which can only be carried out by this means of farming. Moreover, this results in a better type of farmer, greatly improved living conditions, and correspondingly elevated social conditions.

No practical agriculturist can fail to realize the fact that the [illegible] for irrigation in semi-arid conditions in northern latitudes is very great; and that this system of farming will ultimately become a leading factor, and occupy a vitally important place in the agricultural development of Southern Alberta.

[illegible]

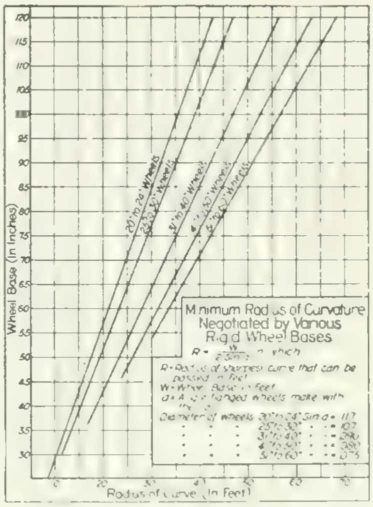
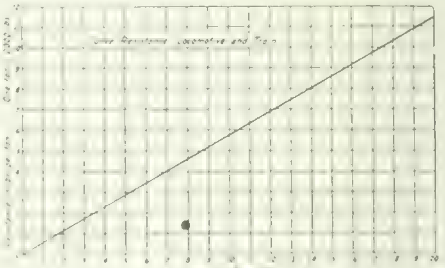
CURVES IN TRACK AND GRADE RESISTANCE.

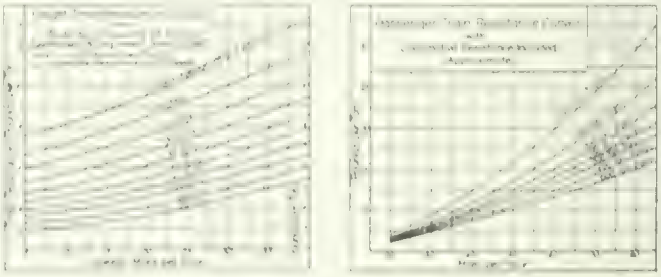
In the United States it is customary to express curvature in degrees, noted by the deflection from the tangent measured at stations 100 feet apart. The following information is abstracted from a bulletin published by the Railway Department of the Westinghouse Electric and Manufacturing Company. The number of degrees of the central angle subtended by a chord of 100 feet represents the "degree curve." One degree of curvature corresponds to a radius of 5730 feet. Therefore, the number of degrees divided into 5730 gives the radius of the curve in feet. Or, the number of feet radius divided into 5730 gives the number of degrees. This assumes that the 100 feet are measured on the arc instead of on the chord, but the error thereby introduced is so slight with curves commonly used that it may be ignored in ordinary calculations.



In English practice it is common to define a curve as one of so many chains (66 feet) radius. Thus the radius of a one-degree curve expressed in chains would be 5730 ÷ 66 equals 86.81, therefore, 86.81 divided by the degrees equals the radius in chains, or 86.81 divided by the radius in chains equals the degrees. The curve shows the value of train resistance on curves.



In the metric system instead of the stations being 100 feet apart they are taken at 20 meters (65.61 feet). The central angle remaining the same, the radius must necessarily be less. This is represented by 65.61 ÷ 100 of 5730 feet for a radius for a one-degree curve or approximately [illegible] United States measurement, which can be used as a factor for converting the United States to the French system.



Curves Showing Train Resistance.

Grade Resistance.—When a train is hauled up a grade, the resistance due to friction is increased by that due to lifting the train against gravity. The amount of this increased resistance is determined as follows:—One mile equals 5,280 feet, and if the grade be one foot per mile, the pull necessary to lift a ton of 2,000 pounds will be $\frac{2000}{5280} = .3788$ pounds.

If the grade is expressed in feet per hundred or per cent., the resistance will be $\frac{2000}{100} = 20$ pounds for each per cent. of grade. Therefore, the grade resistance in pounds per ton = 20 x % grade.

To the grade resistance must be added the train resistance due to speed and friction for level running; i.e., total train resistance on grade equals grade resistance plus train resistance for level running.

The following table is based on the following assumed data:—

Train friction .... 10 pounds per ton
Acceleration .... 20 pounds per ton
Coefficient of adhesion .... 25 %

Weight of Train That Can be Started on a Given Grade.

Weight of Locomotive	TONS WEIGHT OF TRAILING TRAIN				
	GRADE				
	1%	2%	3%	4%	5%
25 tons	225	155	115	90	70
30 "	270	185	135	105	85
40 "	360	245	180	140	115
50 "	450	310	230	180	140
60 "	540	370	270	210	170
70 "	630	430	320	250	200
80 "	720	490	365	280	230
90 "	810	550	410	320	255
100 "	900	615	455	355	285

CONTRACT OBLIGATIONS IN THE STEEL TRADE.*

By E. A. S. Clarke.†

The average buyer of steel has for some years looked upon his contract as an option, the material to be taken if the prices remain satisfactory, but the entire contract to be repudiated if conditions are not favorable. This custom does not apply to all forms of steel, and not at all to raw materials entering into the manufacture of steel. Contracts covering the sale and purchase of ore, coal, coke, pig-iron, and in most cases billets and sheet bars, are practically always strictly carried out. Cancellations of rail contracts are practically unknown. Evidently in the case where the buyer regards his contract as a mere option, a situation arises under which the seller has a heavy tonnage of obligations which he may have to meet, but which the buyer will not take unless conditions are favorable to him. The seller, realizing this, and particularly if the market is advancing, deliberately contracts for the sale of more tonnage than it is possible for him to deliver. The result is dissatisfaction on the part of the buyer at not getting proper deliveries, so that he, in turn, contracts with several sellers for a total of far more than he can use, with the idea that out of the combined contracts he will be able to get the deliveries and amounts that he needs.

As to the causes of this unfortunate situation, the one which in my judgment is chiefly responsible is stated by Mr. J. A. Farrell as follows:—"For the purpose of making a good showing in the volume of sales and contracts, buyers, and particularly the large wholesale merchants, have not infrequently been induced, not to say inveigled, into placing contracts covering as extended a period as possible, for tonnages which they may hope to sell, and in some instances which they can have no reasonable expectation of being able to sell."

Suggested Remedies.—For the correction of these conditions, Mr. Farrell's suggestion that the salesman's remuneration and chance of advancement be made to depend, not upon the volume of his sales and contracts, but upon the profits derived from the goods actually delivered to the buyers, is most excellent. Mr. Bope's suggestion of short-time contracts, no guarantee against decline, preventing the buyer from buying more than he requires for use in any given period, and an equal obligation put upon the seller not to sell more than he can deliver within that period, if properly carried out, would accomplish most of what is necessary, provided that the sales contract contains the elements of mutuality and fairness; and particularly if the seller gives proper heed to his obligations in respect of making deliveries in accordance with his contract.

Investigation shows that the laxity as regards contract obligations which prevails in this country is practically unknown in Europe, and that many of the remedies suggested for the correction of the evil here are in current use abroad. There are in practically every country in Europe certain general sales conditions which vary but slightly between countries and which govern all sales of steel. These fundamental conditions are always stated at the time of making quotations, so that the buyer understands clearly the conditions which will govern the execution of the contract, and there can be no question of some new condition arising after the contract has been signed. These general sales conditions which obtain in Europe seem to the writer eminently fair and reasonable, particularly when stated in advance of signing the sales contract.

A form of sales contract, uniform as to certain fundamental conditions, seems to the writer essential to the proper enforcement of contract obligations. Some of the fundamental conditions which he suggests should be embodied in such a contract are as follows:

(1) The material should be sold for the buyer's use only, and not be re-sold unless first further manufactured. This would have to be modified in the case of sales to merchants or jobbers.

(2) Stipulations as to quality and variations should be clearly stated. In the writer's judgment the best way is to sell the material subject to the seller's standard variations for rolling and shearing, but these should be stated in a list to be published by the seller.

(3) Differentials and extras in the way of price should be clearly understoood, and the seller should publish a similar list covering these items.

(4) Even if prices are quoted at final destination contract delivery should be f.o.b. cars at the seller's works, with freight allowed to destination, the delays and risks of transportation being borne by the buyer.

(5) If the prices quoted include a freight charge, the same should be subject to adjustment in case of increase or decrease in the published freight rate.

(6) Terms of payment and character of funds in which payment is to be made should be clearly stated, and the amount and terms of discount, if any, clearly set forth. It should be made clear that freight charges are to be paid in cash by the buyer, and that they are not subject to discount.

(7) It should be clearly stated that shipments and deliveries under the contract are at all times subject to the ap-

†President of the Lackawanna Steel Company.

proval of the seller's credit department, and that in case of doubt arising as to the buyer's responsibility, further shipments may be suspended until satisfactory assurance as to responsibility is given.

(8) Specifications in detail should be furnished in substantially equal monthly quantities not later than the 15th of the month preceding the month in which delivery is desired; all material to which the buyer is entitled under the contract to be specified at least thirty days prior to the expiration of the contract. Buyer's failure to furnish specifications as aforesaid to be treated at seller's option, and without notice to buyer, as a refusal to accept and receive the unspecified portion of the goods.

(9) The seller should promptly acknowledge receipt of specifications and at the same time advise buyer of the date on which it is expected to begin deliveries against such specifications, and the approximate date at which it is expected to complete the same; such deliveries to begin as soon after receipt of specifications as condition of seller's mill and of its previous sales obligations will permit.

(10) There should be a clause defining the seller's liability for non-performance, and the following is suggested as fair:—"The seller shall not be liable for non-performance of this contract in whole or in part, if such non-performance is the result of fires, strikes, differences with employés, casualties, delays in transportation, shortage of cars or other causes beyond the seller's reasonable control; nor shall these exemptions be limited or waived by any other terms of this contract, whether printed or written; but in the event of unavoidable delay due to fires, strikes or other causes beyond the control of the seller, the buyer may, subject to previously obtaining consent of the seller, cancel the portion of the goods not manufactured or in process of manufacture at the time his request to cancel reaches seller's works. The seller is hereby given the right to have any company in the United States furnish material of the same kind and quality at the same cost to the buyer, in whole or part performance of this contract; and it is agreed that shipments and billing of material by or in the name of such company, as well as any payments made to such company therefor, shall be as effective and binding as if made by or to the seller direct."

(11) The seller's guarantee in regard to defective steel should be clearly stated, and the time and manner in which claims for shortages or other errors, deficiencies or imperfections must be made.

(12) All tests by buyer for physical or chemical requirements and all surface inspection, should be made at seller's mills before shipment, and should be final.

(13) There should be a statement that the contract is made and executed in the State in which the seller's works are located, so that in case of dispute the laws of that State shall govern.

(14) There should be a statement that there are no understandings or agreements relative to the contract that are not fully expressed therein, and that no changes shall be made unless reduced to writing and signed by both parties.

[illegible] the above conditions [illegible] [illegible] should leave little room for [illegible] would be perfectly fair and equitable [illegible] [illegible] [illegible] set of conditions will make a [illegible] [illegible] the conditions which must be lived up to [illegible] and the seller must stand willing to be penalized if he does not make the deliveries agreed to, just as he expects to penalize the buyer for breach of any of his covenants.

Differentials and Extras.—One custom among European steel manufacturers which has struck the writer as being of great value, is that of publishing very complete lists of differentials and extras, covering not only sizes and quality, but also the quantity of one size or section in an individual specification. From these the buyer can tell just what his material will cost him, and is thus enabled to so design his work as to utilize the lowest priced material. The writer believes that a proper differential in price, for quantity of one size specified at one time, would prove a satisfactory solution to all concerned on the question whether large consumers are entitled to a better price than small consumers. Such a basis of differentials is logical because the extra price is charged on account of extra cost. In other words, the buyer, if he requires more expensive service, has to pay correspondingly for it. The writer believes that if a properly prepared schedule of differentials and extras for size, quality and quantity of individual specification were in force, the base price of steel could be considerably lower than under present conditions, without reducing the profits of the seller.

Mr. J. A. Farrell (President of the United States Steel Corporation) in the discussion remarked that contracts for future delivery of material were in a certain sense a means of insurance accorded by custom from sellers to regular consumers to enable buyers to make provision against the future and resell or consume the material at a profit. It was essential that merchants and consumers should be able to calculate precisely the cost of material, to enable them to manufacture and sell over a fixed period. But this period should be a reasonable one and should be limited, so far as possible, in the case of the merchant trade for re-sale to three months from date of contract, and in the case of manufacturing consumers to six months. It was self-evident that in insisting upon buyers carrying out their contract obligations with the same due regard as they expect from sellers, there should be no guarantees against declines. But if any modification of this rule should at any time be permitted, particularly if any deviation was made in contracting for longer than the recognized period, it should be solely against seller's own decline. And there should be a reasonably compensating provision to the effect that if prices should subsequently advance, contract prices should be correspondingly adjusted. It was a distinctly unbusinesslike proceeding to permit buyers to reap any advantage that might accrue from a reduction in the contract price without allowing sellers a similar advantage when there was an advance in price. If contracts were to be made on a fluctuating basis, they should provide for advances during the life of the contract as well as for declines. In other words, the contract should be in all respects mutual. At the time of the formation of the United States Steel Products Company it was found necessary to formulate general conditions of sale. These conditions were made necessary by reason of many practices in vogue in export markets. It might be said that they were acceptable to buyers throughout the world, as an ordinary matter of course, because they clearly defined the obligations of both seller and buyer. Mr. Clarke's suggestion of a uniform sales contract was excellent. The stipulations in such contracts as had been devised by foreign manufacturers and by a number of American manufacturers need only be those which conformed to authenticated legal decisions and which were fair alike to buyers and sellers. If material was sold on contract form which clearly indicated the obligations of both buyer and seller even though the provisions must necessarily be of considerable length, they would form a recognized standard, favorable alike to both buyers and sellers. And they could in turn be made effective between the buyers and their clients, obviating the possibility of misunderstandings and the necessity for legal actions.

THE COATING OF STEEL PIPES.

The commission appointed to report on the water mains of West Australia, known as the Coolgardie main, make certain pertinent comments on the corrosion, which are of considerable interest to engineers.

The commissioners state that the two facts which have brought about external corrosion appear to be:—

(1) Deterioration of the protective coating, regarding which they state:

"It has been found that a coating which appears perfectly satisfactory to the naked eye, contains when examined with a magnifying glass, small holes due to minute bubbles which penetrate right through to the metal beneath. On removing one of the nodular incrustations which form as a result of corrosion, the coating at first sight appears to be sound. A more minute examination, however, reveals the fact that the metal has decayed below the coating, having been attacked by the penetration of the water through one of these minute holes to the metal surface. Were the pipe to be dipped a second time as recommended by the commission, care having been taken that the first coating remained uninjured, the odds against two air bubbles one above the other, giving direct access of the water to the metal, would be enormous.

"It is unfortunate that this recommendation, though no doubt a somewhat difficult one to comply with, does not appear to have been carried out."

(2) The fact that the pipe was buried in trenches when it should have been carried on trestles, so as not to be in contact with the surrounding soil, the soluble salts contained in which give rise to corrosion when moisture is present, regarding which they state:—

"Had the pipes been laid above ground, as recommended by the commission, the external corrosion, as influenced by the soluble salts contained in the soil, would have been entirely done away with."

It is understood that the sandy soil along this pipe line is so impregnated with salt that in many places it absolutely glistens, in which case it is hardly surprising that external corrosion set in.

The coating of steel pipes is a subject to which a great deal of attention has been devoted. If circumstances point to corrosive influences being present from within or without, it is best to order the pipes dipped in special solution, wrapped in hessian and recoated. On reference to the notes quoted from the Coolgardie commissioners' report it is observed that, in their view, had the pipes been dipped twice as this treatment provides, no corrosion would have taken place internally, while, externally, the thick and tough protection provided by the addition of hessian would also have prevented the abrasion of the coating in transit. As evidence of the efficiency of such coating reference may be given to the case of some thirty miles of 30-in. lock-bar pipes for high-pressure gas (similar to the water mains of Coolgardie) which were laid in Staffordshire ten years ago. These mains were laid through heaps of slag and ashes, well known to exercise a highly corrosive action on steel. Inspection of these a year ago shows them to be in as good a state of preservation as when laid, the pipes and coating being intact and bearing every indication that they will remain so for an indefinite period. This main is of particular interest, in that it has remained tight and efficient in spite of the subsidence amounting to feet, due to underground workings.

HYDRO-ELECTRIC STATION AT GATUN SPILLWAY.

Specifications and requisition for auxiliary electrical equipment for the Gatun hydroelectric station have recently been forwarded to the Washington Office for purchase in the United States. This equipment is in addition to the plant purchased some time ago, the first contracts embracing the hydraulic equipment, with the electric generators and exciters. The principal items of the present requisition are the switchboards, oil-switch group, station battery, light and power transformers, and an air compressor, all necessary for the equipping of three complete generating units. A brief description of the waterpower project of the Panama Canal follows:

From the storage in Gatun Lake, there will be available sufficient water to warrant the installation of 6,000 kilowatts in generating capacity, including reserve. The average head throughout the year will be approximately 75 feet, the elevation of the tail race being about eight feet above sea-level. During the rainy season, water will be plentiful and must be wasted over the adjacent Spillway. During the dry season, however, it will be necessary to draw upon the storage in Gatun Lake above elevation plus 79. The maximum quantity of water diverted for hydroelectric development is approximately seven per cent. of the minimum water supply and is the excess which is not required for lockages, evaporation, and leakages. Water will be extremely abundant for several years, until such a time as the traffic through the canal approaches full capacity.

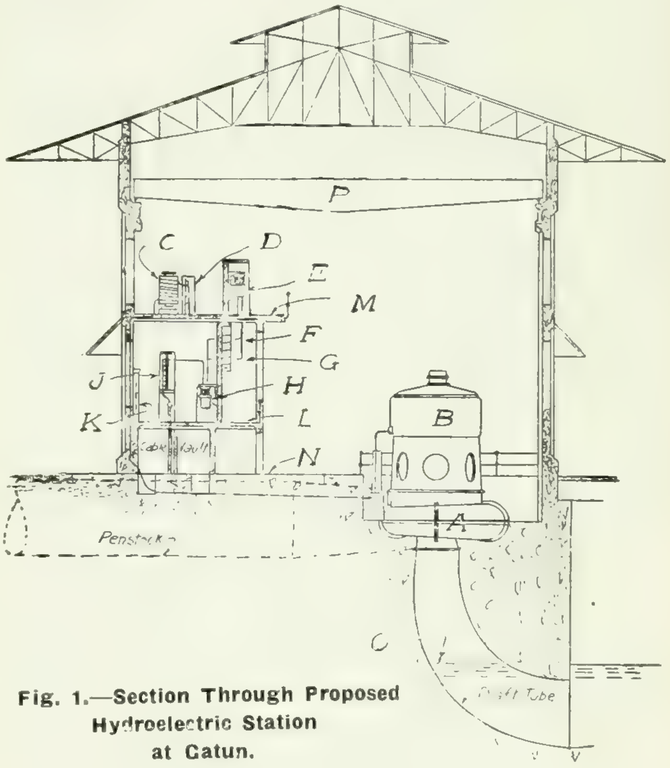

Fig. 1.—Section Through Proposed Hydroelectric Station at Gatun.

The electrical load, which will be connected to the hydroelectric station, consists for the most part of power feeders, which will distribute energy to the machinery of the three locks, to the permanent machine shops, to the dry dock, to the coal handling plant, to the batteries, and to other smaller electric drive which is now giving service. In addition, there will be the lighting load of the locks and of the Zone towns. In all probability, considerable load will be obtained through a service for domestic purposes, electric cooking utensils replacing the stove, in order to create a saving in the cost of fuel, which is an expensive item upon the Isthmus.

There is a slight possibility of an electrification of the Panama railroad over the relocated lines, the electrification depending entirely upon the nature of the traffic conditions that result after completion of the canal. The circuits from the station to the load centres, in general, will be in duplicate, insuring as far as possible an absolutely continuous service. The station will be connected by means of a high voltage transmission line to the present steam generating station at Miraflores, which station will be held in reserve to tide over either shut-down or low-water periods of the Gatun station.

The hydroelectric station is to be situated adjacent to the north wall of Gatun Spillway. The building will be constructed of concrete and steel, and will be of a design suitable for a permanent power house in a tropical country. The dimensions of the building are such as to permit the present installation of the three 2,000-kilowatt units, and provision is made for a future extension of three additional similar units. The building will be rectangular in shape, and will contain one main operating floor, with a turbine pit and two galleries for electrical equipment. The station equipment will include a 30-ton crane to be used during erection and whenever repairs are to be made. The building, with the machinery and electrical equipment, is laid out upon the unit principle. Each unit consists of an individual headgate, penstock, governor, generator, exciter, oil-switch, and control panel. The position of the main features of the development relative to the Spillway channel are shown in Figure 1.

Water is to be taken from Gatun Lake, the elevation of which will vary with the seasons from 79 to 87 feet above sea-level through a forebay which is constructed as an integral part of the curved portion of the north Spillway approach wall. The curved portion of the Spillway wall contains five large apertures into the forebay and will serve as a fender wall to prevent floating debris from accumulating at the headgates.

From the forebay, the water will be carried to the turbines through three steel plate penstocks, each having an average length of 350 feet. The penstocks are to be constructed of [illegible]-inch plates riveted together, and are to be 10 feet 6 inches in diameter inside. The exterior of the penstock is to be surrounded by a thick concrete coating to serve both as a protection against corrosion, and as a means of strengthening the penstock against superimposed earth pressures. The concrete will have a minimum thickness of 12 inches and will be anchored to the steel by means of Z-bars, which are riveted to the plates. The position of the station building relative to the headgates requires that each [illegible] [illegible] and masonry will be entirely covered by the fill of Gatun Dam. Near the lower end of the penstocks, at the building wall, there will be installed a testing link, the purpose of which is to measure, by the velocity method, the quantity of water flowing [illegible]

[illegible] iron headgates, and bar iron trash racks, the latter being [illegible] switch, all operating automatically. The driving machinery [illegible]

present requirements of three headgates, and provision is made for a future addition of three more units.

The turbogenerator units are to be of the vertical type, the entire weight of the rotating element being suspended from an overhung thrust bearing, which is supported from the top shield of the generator. The water turbine proper will be of the spiral casting, one runner, Francis type, and is to be set in heavy masonry foundation. The water will enter the turbine through a tapering joint from the penstock and discharge into an increasing, elbow draft tube, made of ¼-inch steel plates and will be imbedded in the concrete foundation. A section of the station, showing the arrangement of penstock, turbine, and draft tube, is illustrated in Figure 2. The turbine is rated at 2,250 kilowatts at a speed of 250 r.p.m. and will consume approximately 500 second feet of water at full load.

Superimposed upon the turbine casting is to be the generator, a distance ring, six feet in height, separating the two. The generator is to be rated at 2,000 kilowatts, and will deliver 3-phase 25 cycle current at 2,200 volts potential. The turbine, generator, and auxiliary equipment are to be of the best mechanical and electrical construction obtainable. The governor is to be mounted upon one side of the distance ring and is to be geared solidly to the main shaft.

The path of the electrical energy from the generator to the outgoing feeders is shown diagramatically by the heavy line in Figure 2. The leads emerge from the lower part of the generator and pass through a manhole at the base of the turbine into a duct line, which carries the cables to manholes in the cable vault; thence the leads are taken up the building wall in tile ducts to the generator reactances. The reactances are to give protection to the generators in event of severe and protracted short-circuit outside the machines and consist of air insulated coils mounted upon concrete cores; a reactance coil is inserted in each of the three phases of each generator.

Adjacent to the reactances is a concrete cabinet which contains small series and shunt transformers for energizing the instruments and protective devices on the main control switchboard. The generator leads next enter a concrete compartment which houses a pair of oil switches. The two switches permit a selection of connections to either of the duplicate buses, which are situated on the first gallery floor, directly underneath the generator oil switches. The buses are to distribute the energy among the several circuits, each of which is equipped with oil switches. The distributing circuit passes from the circuit switch to an instrument transformer compartment, which is quite similar to the generator instrument transformer compartment. From the instrument transformers, the circuit cables drop into the vertical duct shelves in the cable vault below, thence make an exit from the station through manholes at either end of the building into duct lines at the crest and toe of Gatun Dam. As far as practicable, the entire electrical equipment is in duplicate, and is designed with continuity of service, operating accessibility, and protection of human life as the prime considerations.

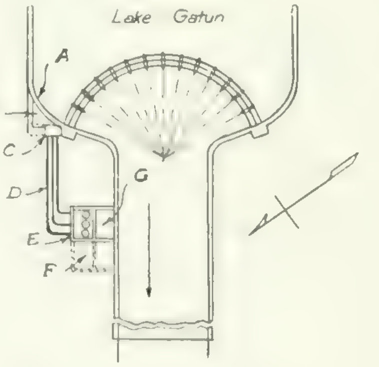

Fig. 2.—Location Plan.

A. Fender Wall.
B. Forebay.
C. Gate house.
D. Penstocks.
E. Power House.
F. Possible extension.
G. Tail race.

One feature of a well designed, modern power house is the remote control of all auxiliary machinery and equipment, particularly of the dangerous switching operations on high voltages. The control and the protecting devices of the Gatun station have been worked out carefully and will permit of an extremely flexible and reliable operation of the generators upon any probable condition of loading. A main control switchboard of the unit panel type is to be erected upon the second gallery floor, where the operator possesses a good view of the entire station. Command of all operations is obtained through master control switches, and indication thereof is procured by means of small pilot (signal) lamps. The operator at the switchboard remotely controls all switching operations, both on the high tension and the exciter buses, and, in addition, controls the headgates, the governors, the rheostats, and the field circuit breakers.

Besides the control switches, the main switchboard contains all indicating, integrating, and recording instruments, which are essential for an intelligent and economical operation of the station. Time limit relays are mounted upon the rear panels to serve as a protection to circuits and generators in case of overload. Continuity of the operating circuit for the control of switches will be obtained by the installation of a storage battery upon the first gallery floor, the switches being mounted upon one panel of the main control switchboard. A voltage regulator, which will automatically maintain a uniform bus pressure, will be assembled upon a smaller station panel at one end of the main board.

The canal commission will try one slight variation from standard practice in an attempt to secure the greatest reliability in the excitation system without the necessity of installing additional water turbine exciter sets. In any alternating current station, it is absolutely necessary that the fields of the alternators be supplied continuously with direct current, usually at 100 to 125 volts potential. When the station is running smoothly, this direct current supply is obtained most economically through motor-driven exciter sets, which are operated directly from the 2,200 volt buses. Two such units, each of 100 kilowatts capacity, will be erected in the Gatun station. Difficulty is encountered, however, when the station is inoperative, as no source of 2,200-volt energy is available to drive the exciter sets. It is customary practice in hydroelectric stations to install independent exciters, which are driven by small water turbines. The small water turbines are more complicated than motor-driven sets, requiring adjustment of governor and of valves, and also additional penstocks and gates, with the resulting complication of operation. At Gatun, each main will be equipped with a 50-kilowatt exciter mounted upon the vertical shaft in the 6-foot space which separates the turbine and the generator. When starting, after complete shut-down, the direct-connected, 50-kilowatt exciters will furnish the necessary excitation until such a time as the motor-driven exciter may be connected to the system. This selection of exciter equipment results in a very simple and easily operated system which possesses ample capacity under all conditions of operation and exceptional reserve in event one exciter is accidentally damaged.

RAIL BREAKAGES.

The weather generally gets the blame for the great railway accidents which are so characteristic of this continent. It is a happy explanation because it is a verdict which doesn't hurt anybody. Extremes of cold and heat are held responsible for the breaking and warping of rails and it has been rather hastily assumed that such "accidents" were unavoidable. The Union Pacific has, however, according to the Wall Street Journal, discovered the secret of avoiding the "unavoidable." Our esteemed contemporary says: "While a joint committee of the railroads and rail manufacturers is wrestling with the problem of eliminating the dangerous breakage of rails, Julius Kruttschnitt and his consulting engineer, John D. Isaacs, have solved the rail problem to so complete a degree that the Harriman lines are far in advance of any other roads in the country in the matter of reduction of rail breakage.

In crucial form the rail problem has been a winter problem. During the winter of 1911-12 there was an epidemic of broken rails on a score of roads, attributed without exception to the severity of the cold weather. The Harriman lines have discovered a remedy for the cold weather rail breakage so effective that the number of the new rails broken during the winter months of 1909, 1910 and 1911 was no greater than the number broken in July or August. Moreover, the cold weather breakage of the new style of rails is far below the breakage of the old style rails in summer months, when they are under least stress.

The secret of the elimination of the broken rail from the Union and Southern Pacific is fundamentally a matter of "section," that is, the shape of rail. The Harriman officials solved the problem by giving the rail a heavier base During the cold weather the base of the rail has a tendency to become bowl shape. In forcing the rail back into shape there is great likelihood of starting a surface fracture. Rails, highly tempered as they are, act like glass. A good scratch on the surface is all that is necessary to cut glass. It is the same with rails. In laying rails the rail is never cut. A slight incision is made on the surface and the rail is broken. With a rail whose base is heavy enough to prevent change of shape in cold weather, obviating the necessity of forcing the rail back into shape, causing surface breaks, the percentage of breakage was reduced to practically nil.

"With 20,000 miles of road offering different styles of rail, all different sorts of climate and traffic conditions, it is obvious that the possible combinations of conditions surrounding rail breakage were infinite," said Mr. Kruttschnitt, "and it is probably for that reason that the task of solution has struck the average railroad official as hopeless. When a series of rail breaks occur, the division officials get panicky and attribute the event to some mysterious factor instead of sitting down to work out the cause.

"We simply went at the situation systematically. Mr. Isaacs suggested that we chart our rail breakages and see if it were possible to discover some law of breakage. We went over our record of breakages to discover whether any blame could be attached to the various kinds of rail, localities or traffic. The result was as simple as astounding.

"We found that the 90-pound rail of the shape in general use gave an average of 6 breakages to the 100 miles during the summer months when the mean temperature was about 75 degrees, and 23 breakages per 100 miles in winter with the temperature around 40 degrees. We found that the rail with heavier base gave only two breakages to the 100 miles in the winter months, the same average as during the summer months, so that so far as the Harriman lines are concerned the rail problem is solved. We are proud of our rail record. We feel that we have solved the problem for all the roads. Of course, we have been careful in giving our orders to the mills we had found most reliable and have insisted on a high grade rail, but it is the shape of rail that has solved the problem fundamentally."

The experience of the Union Pacific is important, because if there is any way of preventing at any cost the deplorable accidents that occur every year through broken rails, there will be a public demand for its adoption, which neither the railway companies nor the legislatures can afford to ignore.

THE CANADIAN NIAGARA POWER COMPANY.

The annual report of the Queen Victoria Niagara Falls Park Commission states that in the month of August, 1911, the Canadian Niagara Power Company, Niagara Falls, Ont., asked permission of the commissioners to proceed with certain alterations and improvements at the entrance to their forebay. The officers and engineers of the company represented to the commission that they had encountered serious difficulties in operating their plant when the ice conditions in the river rendered it practically impossible to keep their intake clear. These conditions were acknowledged to exist by the superintendent of the park, but before taking action the commissioners thought it desirable to submit the matter to an hydraulic expert of large experience, Mr. Henry Holgate, C.E., of Montreal. The nature of the relief asked for by the Canadian Niagara Power Company was:

First.—The building of an ice shield some sixty feet in front of the present ice racks or about one hundred and fifty feet distant from the centre line of the bridge spanning the intake, and parallel with it.

Second.—The construction of an open canal to extend from the water's edge of the Niagara River to the southerly extremity of the forebay for the purpose of increasing the current of water across the intake arches northward to the ice sluiceway, in order to force the ice entering the forebay to pass out into the river.

Third.—The alteration to the entrance of the ice sluiceway so as to provide for more easy access for the water currents carrying ice.

Fourth.—Placing a submerged weir from the northerly side of the intake into the rapids at an angle with the lines of current, so as to provide for the mean water being raised about three feet.

Mr. Holgate reported upon the plans submitted and practically agreed with the company that the works of improvement were necessary for the efficient operation of the plant. He also expressed the belief that they might be carried out under proper restrictions without doing violence to scenic effects.

The commissioners, however, while fully realizing the importance of the company of ameliorating the ice difficulties, could not see their way to adopting the entire scheme of improvements without certain modifications. It was represented by the commissioners that an open canal, however important from an hydraulic point of view, was not a desirable feature for the park at this point, particularly when so much bridge work already existed, and they suggested that the company should construct underground conduits in place of an open canal. Apprehension was also felt that the construction of a submerged weir would tend to destroy the naturally turbulent condition of the surface of the rapids for some distance upstream, and create an artificial millpond appearance. Approval, therefore, of the construction of a submerged weir was withheld until a reliable expert in [illegible] could be consulted on this phase of the matter. To this end the company obtained expert opinion on that special feature of the proposed works from Mr. William Kennedy, Jr., hydraulic engineer, Montreal, acting on behalf of the [illegible]; Mr. [illegible], engineer, [illegible] of the International Waterways Commission, and [illegible] hydraulic engineer, Mr. C. C. Egbert, [illegible] [illegible] [illegible] [illegible] of the water [illegible] the [illegible] of the water surface [illegible]. This plan received the approval of the advisory hydraulic engineer for the board, and the whole matter is now being reduced to an agreement accompanied by plans and specifications. The commissioners, however, are safeguarded by a clause in the agreement distinctly stipulating that, in the event of the irregular blocks not accomplishing the object sought, after a reasonable test, the work shall not be proceeded with.

Simultaneously with the intake improvements the Canadian Niagara Power Company conveyed to the commissioners its intention of proceeding with the power house building to its entire completion, instead of finishing the work by sections as the development and sale of power necessitated. The company also presented a plan for altering the architectural outline of the riverward elevation of the power house, showing a new structure in the centre of the building to be used for office purposes. This slight addition, which was at once approved, completely changes the forebay facade of the building and breaks the lines of a building six hundred feet long without any relieving features. While the company is not adding to the capacity of the station beyond the sixth unit, the additional equipment from time to time required will be placed without serious disturbance to the park, so that the complete restoration of the park surface surrounding the power house may be now finished.

The company now has the following installation completed:—

Generators.	Normal Capacity.	Total.
5	10,000 h.p.	50,000
1	12,500 h.p.	12,500

FORTIER & KILPATRICK, LIMITED.

The prospectus has been issued of Fortier and Kilpatrick, Limited, incorporated under the Dominion Companies Act and licensed to do business in Ontario. The company's authorized capital is $250,000. This company has been formed for the purpose of taking over, for the province of Ontario—excepting Port Arthur and the territory lying north of the Canadian Pacific Railway between Port Arthur and Mattawa—the patent rights and also the sole right to manufacture sewer pipe with the Thomas glazed cement sewer pipe machine, also, the sole rights to manufacture and deal in Trojan partitions and ceilings, stonewood plastic flooring, sarco asphalt and waterproofing. The company have several side lines, such as washable water paint, asphalt, etc., and the right to engage in any other manufacturing and mercantile business which may be conveniently carried on therewith.

Patent rights for the Thomas glazed cement sewer pipe machine and the right to manufacture Trojan partitions and ceilings and stonewood and Trojan flooring and Sarco asphalt and waterproofing and Trojan washable water paint are being purchased and acquired by Thomas Mills for $90,000, payable as follows:—$20,000 in the capital stock of Fortier and Kilpatrick, Limited, consisting of 200 fully paid and non-assessable shares, and $[illegible] in cash.

Fortier and Kilpatrick, Limited, in addition to the purchase of the Thomas glazed cement sewer pipe machine, and all rights connected therewith for the territory named, have also purchased the rights, patents, formulas, secret processes, etc., of the Interior Construction Company of Winnipeg for the following utilities: "Trojan" partitions, ceilings, etc., "Trojan" plastic sanitary floors, and Thomas glazed cement sewer pipe.

An offering of $[illegible] [illegible] of the company is being made at par. The proceeds from the sale of this stock will be devoted to acquiring the above named rights and patents and for putting money into the company's treasury to manufacture the same. The following are the directors of the company:—Messrs. John H. Hudson, manufacturer, 93 Bernard Avenue, Toronto; George R. C. Merriam, president Traders Limited, 31 Adelaide Street West, Toronto; W. E. Whitehead, manufacturers' agent, 355 Palmerston Boulevard, Toronto; James Aitchison, barrister, Canada Life Building, Toronto; Thomas Mills, banker, 79 Clarence Street, Kingston.

◆

PERSONAL.

MR. S. HETT. B.A.Sc., has been appointed engineer in charge of revision for the Hudson Bay Railway.

MR. McARTHUR is being mentioned for the position of engineer for the municipality of Regina.

MR. E. M. KINDLE, A.B.M.S., Ph.D., a member of the United States Geological Survey, has been appointed invertebrate palaeontologist on the Geological Survey of Canada.

MR. DUNCAN McDONALD has retired from the position of manager of the Montreal Tramways Company. His position is being taken by Mr. James E. Hutcheson, of Ottawa.

MR. W. H. FISK, who has been connected with the Mackenzie-Mann interests in Mexico for the past five years, will probably be appointed to succeed Mr. W. B. Boyd as Chief Engineer of the Toronto Power Company, the Electric Development Company and the Toronto Railway Company.

MR. JAMES MILNE has been appointed electrical and mechanical engineer for the city of Toronto. Mr. Milne is at present manager of the Ontario Salt Works, Windsor. He is of Scottish birth, is 45 years of age, and has resided in Canada for twenty years. Eighteen years ago he was a teacher of mechanical and electrical engineering in the Toronto Technical School, and he has had a wide experience since that time. Mr. Milne is a street railway expert in addition to his other qualifications.

MR. ALFRED STILL, who left England in the early part of last year to take up the position of electrical engineer to the Lake Superior Power Co., of Sault Ste. Marie, Ontario, Canada, has lately been appointed chief electrical engineer the the mining department of the Algoma Steel Corporation. His headquarters will be at Magpie Mine, Ontario, where he will have charge of the electric power equipments at the various mines controlled by the company, and will also be responsible for the completion and operation of the 4,000 h.p. hydro-electric generating station connected to the mines through an 18 mile three phase overhead transmission. Mr. Still is an Assoc. M. Inst. C. E. and a member of both the American and British Institutions of Electrical Engineers.

◆

TOWN PLANNING CONGRESS.

Uuder the auspices of the Winnipeg Town Planning Commission and the Winnipeg Industrial Bureau, the first Canadian Housing and Town Planning Congress was opened in the auditorium of the bureau on July 15th last.

The president of the Winnipeg association occupied the chair, and introduced Mayor Waugh, of Winnipeg, who spoke of the object of the gathering, why it was convened, what had been done, and what it was hoped to do. The congress was called together to devise plans and means to make every city and town more beautiful, and a more attractive place in which to live—to get residents to take more pride in their houses and the surroundings.

At the afternoon session of the congress W. Sanford Evans presided, and the meeting was addressed by Dr. Charles A. Hodgetts, medical adviser to the commission of conservation, Ottawa, on "The Housing Problem"; Dr. M. M. Seymour, Regina, commissioner of public health for Saskatchewan, on "The Tenement House Question"; and a paper by Frederic Law Olmstead, chairman of the International Housing and Town Planning Congress Committee, Brookline, U.S.A., on "The Four Cardinal Points of Town Planning," was read by Dr. Perry. The general trend of the papers was in strong condemnation of the tenement residence and apartment house, which subsequently degenerated into a tenement against the evils of overcrowding; and an earnest appeal for legislation empowering the municipality to have stringent control over such houses and conditions within them, for the good of public health and the vitality of the people.

In connection with the congress an exhibition of town planning, garden cities and schemes for improvement was illustrated by plans, photographs, charts and other data. The exhibit was displayed on the four walls of the room in which the meetings were held.

The Social Museum of Harvard University contributed a series of pictures and plans. The series included views of housing conditions in several cities; of garden suburbs; of city planning; of model cottages and modern dwellings. A feature of this exhibit was the illustrations of slums and slum life in larger cities of the old and new worlds. Attention was drawn to the dark bedrooms of the slum-areas where crowded humanity lives and suffers, from which sunlight and fresh air are excluded by gigantic skyscrapers. The methods adopted to remove the eyesore by the erection of attractive dwellings and by the creation of open spaces is indicated. There was a large assortment of exhibits from cities in the United States, New York, Kansas, Minneapolis, Tampa, Florida, New Orleans, Louisville, Harrisburg, all contributing; but the feature was supplied by a few of the plans of the proposed improvements in Chicago; and which represent a scheme which had foresight been employed a few years ago would have saved the city no less a sum than $300,000,000. Kansas City views showed park situations before and after improvement. Pittsburg was represented by an eyesore, as the exhibit is a view of an open sewer in the middle of a street which exists to-day.

The model towns of England, Bournville and Port Sunlight were beautifully illustrative of the ideal the city-planner aims at. Liverpool had an exhibit showing the improvements effected in the slum district of the Bevington area, necessitated by the "Housing of the Working Classes" Act. The garden suburbs of Hampstead, with the grouping of co-operative housing which eliminates the servant problem, were effectively shown. Edinburgh, old and new, its magnificent streets and fine buildings were illustrated in a series of photographic views. Manchester and Birmingham each had their representative exhibits. Germany and conditions in Germany were adequately shown, but of especial mention were certain Mannheim views, where the usually hideous gas tank is made an architectural centre from which the streets of the town radiate, and the interior park arrangement for sunlight and fresh air, adapted in the "Alfredshop" colony, Essen.

France was illustrated in a garden suburb and model village views. Perhaps the most interesting exhibit of all was the newspaper cuttings of the plans for the new federal capital of Australia, Vass-Canberra, New South Wales, which took first and second places respectively in the competition; while also shown was a copy of one of the competitive designs for the city improvement of Montevideo, conducted by the Republic of Uruguay.

The following is a partial list of delegates:—

Mayor Waugh, C. D. Sheppard, J. W. Harris, Dr. Mattice, J. D. Atchison, C. F. Bennett, H. Falk, H. Edwards, W. W. Willis, Winnipeg; J. T. May, C. Chambers, Toronto; J. P. Gilroy, Isaac Cowie, N. T. McMillan, W. Fingland, R. S. Ward, R. Martinson, W. Pearson, C. F. Roland, W. Sanford Evans, Paul Clemens, G. F. Chapman, W. Furnival, Winnipeg; M. H. Ross, Regina; M. Wilson, F. Saunders, J. Antonison, T. J. Townshend, Moose Jaw; Dr. T. H. Hodgetts, Ottawa; A. W. Boilfus, Chicago; M. L. Kenzie, Brandon; J. East, Dr. Whitlaw, Edmonton; Victor Mager, St. Vital; J. P. Marshall, Battleford; W. Smith, Kirkella; H. Goodie, Port Arthur; Mayor Armstrong, Edmonton; J. Caldwell, Virden; A. M. Jeffries, Edmonton; H. D. Pickhard, Brandon; G. W. Hayler, London.

COMING MEETINGS.

THE WESTERN CANADA IRRIGATION ASSOCIATION.—Sixth Annual Convention at Kelowna, Okanagan Valley, B.C., August 13, 14, 15 and 16, 1912. Secretary, Normon S. Rankin, P.O. Box 1317, Calgary, Alta.

THE UNION OF CANADIAN MUNICIPALITIES.—August 27, 28 and 29. Meeting at City Hall, Windsor, Ont. Hon. Secretary-Treasurer, W. D. Lighthall, K.C.

CANADIAN FORESTRY ASSOCIATION.—Convention will be held in Victoria, B.C., Sept. 4th-6th. Secy., James Lawler, Canadian Building, Ottawa.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Second Annual Meeting to be held in Toronto, Sept. 16, 17 and 18.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Annual Assembly will be held at Ottawa, in the Public Library, on 7th October, 1912. Hon. Sec'y, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

EIGHTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.—Opening Meeting, Washington, D.C., September 4th, 1912. Other meetings, Business and Scientific, in New York, beginning Friday, September 6th, 1912 and ending September 13th, 1912. Secretary, Bernhard G. Hesse, Ph. D., 25 Broad Street, New York City.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, Mr. Hugh B. Fergusson, 409 Carter Cotton Bldg., Vancouver, B.C. Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-jack. Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION.—President, Mayor Lees, Hamilton; [illegible] Treasurer, Mr. K. W. [illegible], County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George [illegible]; Sec.-Treasurer, E. Hingley, Regina, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta.; Sec.-Treasurer, [illegible], Alta.

THE UNION OF CANADIAN MUNICIPALITIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, [illegible]; Hon. Secretary-Treasurer, J. W. McCready, City Hall, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor [illegible]; Sec.-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor [illegible], B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey [illegible].

UNION OF ALBERTA MUNICIPALITIES.—President, Mayor Mitchell, Calgary; Secretary-Treasurer, [illegible], Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewit, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President, J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Jas. Anderson, Gen. Mgr., Sandwich, Windsor and Amherst Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, A. F. Wickson; Toronto. Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5 Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman; Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Hon. W. R. Ross, Minister of Lands, B.C. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phoenix Block, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only, unless otherwise noted, at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close		Noted in issue of
8-5—	Electric Generating Machinery, Canora, Sask (S.)	7-18

(Canora specifications are also on file at the office of The Canadian Engineer, Rooms 617-628, Transportation Building, Montreal.)

◆

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

Place of Work.	Tenders Close.	Issue of.	Page.
Boisedale, N.S., wharf	July 24.	July 11.	68
Calgary, Alta., three bridges	July 31.	July 11.	67

TENDERS.

Banff, Alta.—Tenders for the erection and completion of a public school building at Banff, will be received up to July 27th, 1912, plans and specifications at the office of the architects, Messrs. Lang and Major, Suite 11, Board of Trade Bldg., Calgary, or William Mather, Banff, Alta.

County of York, Ont.—Mr. Frank Barber, engineer of this county, will receive tenders up to noon Monday, July 29th, 1912, for the construction of a concrete retaining wall at Eagle Bridge on the Humber River. (See advt. in this issue of Canadian Engineer.)

Edmonton, Alta.—Tenders for the supply of hardwood doors for the south wing and rotunda of the Parliament Buildings, Edmonton, will be received up to July 26th, by John Stocks, Deputy Minister of Public Works, Edmonton. Specifications etc., at the structural engineer's office, New Parliament Buildings, Edmonton, and at the branch office of Dept. of Public Works, Calgary.

Fort William, Ont.—Tenders for a new public school, Wayland addition, will be received until July 25th. Plans and specifications at the office of R. E. Mason, architect, Victoria Block, Fort William.

Fort William, Ont. — Tenders for alterations and additions to public school, Schreiber, Ont., to be received until July 24th. Plans and specifications at the office of R. E. Mason, architect, Fort William.

Fork River, Man.—Tenders for the erection of a steel bridge across Fishing River, 30-ft. span, will be received by D. F. Wilson, sec-treas. Massey River Municipality, Fork River, Man., until July 27, 1912.

Hamilton, Ont.—Tenders for the construction of sewers on a number of streets and avenues will be received until July 24th, 1912. Plans and specifications at the office of the City Engineer. S. H. Kent, city clerk.

Moose Jaw, Sask.—The City Commissioners will receive tenders until August 1st, 1912, for the supply and delivery of the following f.o.b. cars Moose Jaw:

160 6.6 ampere series metallic flame lamps.
150 automatic cut out hangers.
Mercury rectifier and other station equipment for 200 6.6 ampere lamps.

Specifications, etc., may be obtained on application to J. D. Peters, electrical superintendent, Moose Jaw.

New Liskeard, Ont.—Tenders for the construction of about 26,000 square feet of cement sidewalks in the town of New Liskeard will be received until August 1st, 1912. Plans, etc., at the office of C. H. Fullerton, town engineer. J. I. Dixon, clerk. (See advt. in Canadian Engineer.)

Ottawa, Ont.—The Dominion Government is calling for tenders for the construction of the Government elevator at Port Arthur, bids to be in by August 1st.

Ottawa, Ont.—Tenders for the construction of a new drill hall at Minnedosa, Man., will be received until noon of July 24th, 1912. Specifications at the office of the Officer Commanding Military District No. 10, Winnipeg; Officer Commanding "D" Squadron, 12th Manitoba Dragoons, Minnedosa, Man.; the Director of Engineer Services, headquarters, Ottawa, and at the office of the District Engineer, Fort Osborne Barracks, Winnipeg. E. Fiset, Deputy Minister, Department of Militia and Defence, Ottawa.

Ottawa, Ont.—Tenders for the supply of coal for the public buildings throughout the Dominion will be received by the Secretary Dept. of Public Works, Ottawa, up to August 28th, 1912. Specifications, etc., at the secretary's office. (See advt. in Canadian Engineer.)

Ottawa, Ont.—Tenders for the construction of a Model and Gun Shed at Royal Military College, Kingston, Ont., will be received by the Director of Contracts, Dept. of Militia and Defence, Ottawa, up to noon of July 2[illegible], 1912. Specifications, etc., at the offices of the Officer Commanding the No. 3 Divisional Area and the Commandant Royal Military College, Kingston, Ont.; and the Director of Engineer Services, headquarters, Ottawa. E. F. Jarvis, Acting Deputy Minister, Dept. of Militia and Defence, Ottawa. (See advt. in Canadian Engineer.)

Ottawa, Ont.—Tenders for dredging required at Weymouth, N.S., will be received at the office of R. C. Desrochers, Sec. Dept. of Public Works, Ottawa, until July 24th, 1912. Full particulars at the office of the secretary.

Ottawa, Ont.—The Dept. of Militia and Defence will receive tenders up to noon of August 6th, 1912, for the construction of a new drill hall at Omemee, Ont. Specifications, etc., at the offices of the Officer Commanding the 3rd Division, Kingston, Ont.; Officer Commanding "D" Company, 45th Regiment, Omemee, Ont.; and of the Director of Engineer Services, headquarters, Ottawa.

Ottawa, Ont. — Tenders will be received by the Secretary Department of Public Works, Ottawa, up to July 31st, for interior fittings, post office, Strathcona, Alta. Plans, etc., to be seen on application to Mr. D. F. McHardy, clerk of works, Strathcona, Alta., and at the Department of Public Works, Ottawa.

Ottawa, Ont.—The Dept. of Militia and Defence will receive tenders up to noon of August 6th, for the construction of a new drill hall at Norwood, Ont. Specifications at the offices of the Officer Commanding 3rd Division, Kingston, Ont.; Officer Commanding "E" Company, 40th Regiment, Norwood, Ont.; and the Director of Engineer Services, headquarters, Ottawa.

Ottawa, Ont.—Tenders for the construction of an extension to West Breakwater at the entrance of Cobourg Harbor, Ont., will be received until August 14th, 1912. Plans, etc., at the offices of J. G. Sing, Esq., district engineer, Confederation Life Building, Toronto; J. L. Michaud, Esq., district engineer, Merchant Bank Building, Montreal, Que.; on application to the Postmaster at Cobourg, Ont., and at the office of R. C. Desrochers, Secretary Department of Public Works, Ottawa. (See advt. in Canadian Engineer.)

Regina, Sask.—Sealed tenders for "electrical plant" will be received by the City Commissioners up to noon of September 14th. (See advt. in Canadian Engineer.)

Toronto, Ont.—Tenders will be received up to and including the first day of October, 1912, for the right to cut white and red pine and spruce in the district of Nipissing, Ont. For full particulars apply to W. H. Hearst, Minister of Lands, Forests and Mines, Toronto. (See advt. in Canadian [illegible]

Toronto, Ont.—The Chairman of the Board of Control will receive tenders up to noon on Tuesday, August 13th, 1912, for the construction and erection of the drip guards on the Lansdowne Avenue subway. (See advt. in this issue of Canadian Engineer.)

Vancouver, B.C.—The Dept. of Public Works will receive tenders until August 1st, for alterations to Lobnitz Rock Cutter No. 1. Plans, etc., at the office of William Henderson, Esq., res. architect, Victoria, B.C.; C. C. Worsfold, [illegible] Westminster [illegible] British Columbia, Post Office Bldg., Vancouver, B.C.

Victoria, B.C.—Tenders are being invited by the De- [illegible] Public Works [illegible] at Crescent Valley and Nicola, and for the construction of a [illegible]

Watford, Ont.—Tenders will be received up to August [illegible]

Winnipeg, Man. [illegible] advt. in Canadian Engineer.)

York Township, Ont.—Tenders for concrete sidewalks [illegible]

CONTRACTS AWARDED.

Arden, Man.—The contract for the erection of the steel bridge, with concrete abutments, over Grassy River, has been awarded to the Algoma Steel Bridge Company, at $4,586.

Edmonton, Alta.—Wharf: Contractors, Smith Bros., Ltd., of Edmonton.

Embro, Ont.—Messrs. Bain and Ross have the contract for building a large cement breakwater at London.

Fort William, Ont.—The contract of Messrs. Stewart and Hewitson for the grading and graveling of Southern Avenue has been accepted.

Gananoque, Ont.—The contract for the new armouries building in Gananoque has been let to John Dillon, of Seeley's Bay. His tender was $1,500 less than the next lowest. Work is to be commenced at once.

The tender of E. A. Blakeley, Ottawa, has been accepted by the department of public works, for the erection of the new post office building in Gananoque, at the corner of King and Stone Streets. It is understood that work will be started at once.

Guelph, Ont.—Messrs. Taylor Bros., of this city, have secured a contract from the authorities of the Agricultural College to erect a large barn. The moving of a residence for the same authorities has been awarded to Mr. Rogers.

Kemptville, Ont.—Public building: The Dominion Concrete Co., Ltd., of Kemptville, Ont.

Kerrisdale, Point Grey, B.C.—At the meeting of the council contracts were awarded as follows: Grading Salisbury Street, J. Cameron; clearing Eighteenth Avenue, Linberg and Lund.

Medicine Hat, Alta.—The contract for the building of the new Union Bank has been awarded to Mr. N. Healy, of Calgary, whose tender was $27,000.

The Lussier Construction Co. have the contract for the erection of the public school at South Yuill. The contract price is $40,000.

Miramichi Bay, N.B. — Dredging: Contractors, The Northern Dredging and Construction Co., Ltd., of Chatham, N.B.

Moose Jaw, Sask.—Messrs. A. P. Smith Manufacturing Company, East Orange, N.J., have been awarded the contract to furnish a number of water gates as required by the municipal council.

New Westminster, B.C.—The Powers Construction Company, of Vancouver, have been awarded the contract to erect the horse show building and arena. The price for this work is $17,5[illegible]5.

New Westminster, B.C.—The contract for the supply and erection of the steel roof trusses for the horse show building and arena has been awarded to Messrs. John Coughlan and Sons of this city, at a price of $5,500.

New Westminster, B.C.—The municipal council accepted the tender of the Schaake Machine Works to supply a number of manhole covers at $12.80 each.

New Westminster, B.C.—Messrs. Gilly Bros. have been awarded a contract to supply about 2,000 feet of sewer pipe to the municipal council.

Province of British Columbia.—The Dominion Bridge Co., of Lachine, Que., and the Canadian Bridge Co., of Walkerville, Ont., have been awarded the contract to supply and erect the super-structures of ten railway bridges for the Canadian Northern Railway in this province.

The Armstrong Morrison Co., Vancouver, and the John Galt Engineering Co., of Winnipeg, have received the contract to supply and erect the substructures of eight bridges for the C.N. Railway in this province.

Sault Ste. Marie, Ont.—Dredging: Contractors, The Soo Dredging and Construction Co., Ltd., of Sault Ste. Marie.

Toronto, Ont.—Tenders for the new wing of Pape Avenue School and also for the enlargement of Perth Avenue School were opened and the following tenders accepted:

For Pape Avenue School:—G. T. Gayton, mason and steel work, $[illegible]; [illegible] and [illegible], carpenter work, $7,400; F. Armstrong and Co., heating and ventilating, $[illegible] and plumbing, $[illegible]; [illegible] Flowers, roofing and tinsmithing, $[illegible]; fireproof floors, R. Bennett, $1,0[illegible]; and plastering, [illegible] Jackson, $[illegible]

Main Street, Picton, Ont., showing the Tarvia Modern Pavement.

Picton's Experience with Tarvia Modern Pavement

Mr. C. B. ALLISON, Mayor of Picton, Ont., has written the following letter, which constitutes so complete an account of Tarvia that we will let it serve for our whole advertisement:

Corporation of Picton
Office of the Mayor Picton, Ont., November 25, 1911.

"Last year the Council of the Corporation of Picton decided to build as good a road as possible on part of the main street where the traffic is very heavy.

After careful investigation they came to the conclusion that the Tarvia road was the best suited for the existing conditions and the amount of money to be spent. The road was built *in the summer of 1910* and has given excellent satisfaction in every way. The surface is very hard and has withstood the heavy traffic without showing any signs of wear. Some doubt was expressed as to the possibility of the road standing the heavy frost, but on examination *in the spring* the road did not show any sign of having been damaged during the winter.

Judging from the satisfaction that this section of the road has given, I feel sure that during the year 1912 the Council will build more of the Tarvia road on our main street, and continue doing so from year to year, until the whole of our main thoroughfare is constructed of this most excellent road.

I might state that personally I do not believe a better road can be built, considering the amount of money expended and material used, than that which is built with Tarvia.

Yours very truly, (Signed) C. B. ALLISON, Mayor."

THERE are three kinds of Tarvia—"Tarvia X" for road and pavement construction, "Tarvia A" for surface work, and "Tarvia B" for dust suppression and road preservation. The first two are very dense and viscid and require heat for application. "Tarvia B" is applied cold.

Booklets free on request.

THE PATERSON MANUFACTURING COMPANY, LIMITED
MONTREAL TORONTO WINNIPEG VANCOUVER

THE CARRITTE-PATERSON MANUFACTURING CO., LIMITED
ST. JOHN, N.B. HALIFAX, N.S.

At Perth Avenue the contract for mason and steel work was awarded to W. T. Joy, $18,550; carpenter work, Crocker and Ledrew, $9,800; plastering, G. White, $2,595; painting, R. G. Johnston, $1,115; iron stair, Canadian Ornamental Iron Co., Ltd., $3,300; roofing and tinsmithing, A. Matthews, Ltd., $1,698.

Welland, Ont.—Mr. W. E. Hardison, of Welland, under the firm name of The Welland Dredging Company, has been awarded the contract to remove the sandbars which block the entrance to the canal at Kingsville.

Winnipeg, Man.—Mr. C. W. Hall, of this city, is the successful tenderer for the building contract for the new arena of the Winnipeg Fair and Live Stock Association. The contract for the steel work of the structure was some time ago awarded to the Wisconsin Steel and Iron Company of Chicago.

◆

RAILWAYS—STEAM AND ELECTRIC.

British Columbia.—The experiment of burning oil in the locomotives of the Canadian Pacific Railway through the Rocky Mountains has so far proved a decided success.

British Columbia. — Messrs. Waddell and Harrington, consulting engineers, have prepared designs for ten railway bridges, the contracts for which have recently been awarded. They are for the Canadian Northern Railway.

Halifax, N.S.—The operation of the Halifax Electric Tramway Company still continues to make increased profits as shown by the following: Receipts for the week ending July 14th, 1912:

1911.	1912.	Increase.
[illegible]	[illegible]	$416.45

Montreal, P.Q.—A company known as the National Steel Car Company has been organized with offices at the Transportation Building with a capital of $6,000,000.

Revelstoke, B.C.—Canadian Pacific officials here are considering the report of the engineers in the field trying to get a better grade for the proposed double-track of the line through the mountains. It is stated that surveys show that by driving of a tunnel for a distance of five miles through the Selkirks, starting at Bear Creek and emerging below Glacier, a new grade that will be less than one per cent. against western traffic will be available. By a diversion at Notch Hill, just east of the Kamloops, the grade there could be cut down to the same, which would make one per cent. the maximum from Calgary to the coast. It is stated that the company will proceed with this work of double-tracking in order to have the easy grades available for the handling of wheat crops by the time of the opening of the Panama Canal.

◆

LIGHT, HEAT AND POWER.

Harrison, Ont.—There is a possibility of new electric lighting methods being adopted in the town owing to the [illegible] of the plant now furnishing the supply that the service will be discontinued after [illegible]. The plant is badly in need of repair.

Ottawa, Ont.—The Dominion Government Commission [illegible] countries, [illegible] of others. [illegible] commercial exploitation [illegible] demonstrated.

COPIES OF THE ENGINEER WANTED.

[illegible]

GARBAGE, SEWAGE AND WATER.

Calgary, Alta.—The city council has passed a by-law providing for the construction of a filtration plant at a cost of $400,000.

Fort William, Ont.—Owing to a mistake in the estimation of a tender for the construction of a sewer the contractors have asked to be released from the agreement. The council will do the work by day labor and apply the contractors' deposit cheque toward the expense of the same.

Montreal, P.Q.—The medical health officer has petitioned the council in order that the practice of cutting off the water supply of persons in arrears of payment be stopped claiming that in many instances these persons are the ones most in need of the substance.

Moose Jaw, Sask.—The following tenders for the supply of high pressure hydrants have been received by the council:

Florence Iron Works, per R. D. Wood and Co., 8 inch connection with main three nozzle openings, $175 each; same with flange connection, $175; same with universal connection, $177.

Wilson, Townsend and Saunders, same hydrant as per specifications furnished by city, $180; with flange connection, $180; with universal connection, $190. Second proposition delivery of 40 hydrants in 90 days at $180 each and balance by May 15, 1913, at $170 each.

The A. P. Smith Manfg. Co., East Orange, N.J., U.S.A., hydrants as per specifications, $134.55; flange connection, $134.55; universal connection, $135.85. Second proposition to deliver in 45 days forty hydrants at $134.55, and balance by May 15th, 1913, at $134.55.

The Kerr Engine Co., of Walkerville, Ont., hydrants as per specifications, $242.30; with flange connection, $242.30.

Drummond McCall Co., of Montreal, hydrants as per specifications, $147.50; flange, $151.75; with universal connection, $150.40. Second proposition to deliver forty hydrants in ten weeks at same price and balance by May 15, 1913, at the same price.

Ste. Cecile, P.Q.—Owing to a severe pollution in a well which serves many families in this community with water, the city of Montreal will lay a temporary pipe line. The distance between the two municipalities is several miles.

Toronto, Ont. — The municipal council have ordered plans prepared for an extension of the filtration plant. Mr. Allen Hazen will execute this work.

Welland, Ont.—The new municipal water plant has been placed in operation with satisfactory results.

◆

BUILDINGS AND INDUSTRIAL WORKS.

Eburne, B.C.—A report states that the British Columbia Electric Railway are making preparations for a new station and freight shed for this point.

Fraser River, B.C.—The Department of Marine and Fisheries are making preliminary arrangements for the erection of a lighthouse on this river. Tenders will be called for its construction soon.

Fredericton, N.B.—The Fire Committee have received instructions from the council to proceed with the erection of a new fire station at a cost of $12,000.

Galt, Ont.—The management of the Galt Robe Works are making preparations for an expansion of their present plant.

Mitchell, Ont.—The White Packing Company, of Stratford, are making arrangements for the erection of a cold storage plant at this point.

Montreal, P.Q.—The Christian Brothers, of Longueuil, are making preparations for the erection of a technical school. Government aid will be sought for the new project, and, if secured, work on the building will be inaugurated without delay.

Port Arthur, Ont.—A British firm of iron workers trading under the name of [illegible] Company, will locate a branch factory in this city. The firm specialize in valves, hydrants and structural steel.

Port Arthur, Ont.—A report states that preliminary arrangements are under way for an enlargement of the Prince Arthur Hotel. Mr. McLean is manager of this business.

Quebec, P.Q.—Tenders for the construction of pier No. 2, which will extend from the Louise Embankment northeast into the river St. Charles, parallel with the breakwater extension, will be advertised in a few days. The construction of

this pier with the dredging necessary is estimated to cost about $1,000,000.

Saskatoon, Sask.—Mr. Frank Cahill is making preparations for the erection of a $75,000 business block in this city.

St. Catharines, Ont.—The Canadian Bank of Commerce has started work on a new office structure in this city. Mr. Connelly is the local manager.

St. John, N.B.—The management of the Union Foundry and Machine Works are making preparation for several changes which are to enlarge the plant to a considerable extent. Mr. George H. Waring is president and manager of this concern.

St. Thomas, Ont.—The local corps of the Salvation Army are making arrangements for the enlargement and remodelling of the barracks. This work will entail an expenditure of about $7,000.

Toronto, Ont.—The management of the Union Stock Yards in the western portion of this city have let a contract for the construction of a cattle pen with a capacity of five thousand head of sheep. Many additions to the cattle pens are planned for the early part of 1913.

Victoria, B.C.—The municipal council are about to alter the market building in order to improve the police station accommodation.

Welland, Ont.—The management of the Metal Chemicals, Limited, have purchased the property formerly occupied by the Electro Steel Company and ten acres of adjoining property. They will reconstruct the plant for the purposes of refining cobalt and other ores. Officials of the company are all New York men. They are: President, Joaquin W. de Aguero; vice-president, E. de Aguero; secretary-treasurer, J. H. Charles; director, G. W. Van Ness; chemical expert, Prof. Richardson. Mr. Charles is also secretary-treasurer of the Mussen Book Company.

Western Canada.—The management of the Hart Accumulator Company, of London, England, are considering the establishment of a branch factory in this country. Winnipeg and Fort William are being considered as probable locations.

Winnipeg, Man.—The Knights of Columbus and Catholic Club of Winnipeg have had plans prepared and will start work on a new building 120 x 70. The building will be of fireproof construction and will cost about $150,000. The contracts will be awarded this fall.

◆

BRIDGES, ROADS AND PAVEMENTS.

Moose Jaw, Sask.—Moose Jaw Construction Co., laying 373,380 square feet of walks at 15⅞ cents per square foot, or $59,274.07; laying 78,000 lineal feet of curb and gutter at 62½ cents per lineal foot, $48,750.

Rawlins, Lowndes, laying 373,380 square feet at a price of 18 cents per square foot, also laying 78,000 lineal feet of curb and gutter at 55 cents per lineal foot.

L. C. Gibson and Co. tender for work north of the C.P.R. tracks approximately 200,000 square feet at 18 cents per square foot; laying 50,000 lineal feet of curb and gutter at 55 cents per lineal foot. For work in South Hill curb and [illegible] cents per lineal foot, and sidewalks [illegible] cents per square foot.

Moose Jaw, Sask.—Plans have been submitted to the council showing the method of strengthening the Fairford Street and Athabasca Street culverts. This work is estimated [illegible]

CURRENT NEWS.

Montreal, P.Q.—The [illegible]

water and coming from the plant of a local manufacturer. It is the intention of the authorities to prosecute on account of a possibility of disease producing organisms being among the number.

Ottawa, Ont.—The Federal Government are considering the construction of two fishery protective cruisers for the Pacific Coast and are inviting proposals for their construction. They are to replace the cruisers now in place and are to be much faster.

Ottawa, Ont.—Government jobs aggregating four million dollars will be put at tender this week. There are two big harbor works, one at Quebec and the other at Victoria, each costing two million dollars. The Quebec improvement consists of the construction of another large pier for ocean liners, along with sheds, and considerable dredging and filling.

Ottawa, Ont.—A peculiar circumstance is again noted in connection with the recent outbreak of typhoid fever in this city and while there are quite a number of cases on the Ottawa side of the river, in Hull there is only one case of typhoid known to the authorities. It will be remembered that while Ottawa suffered from the severe epidemic of typhoid last year, the disease was practically unheard of in Hull. This is taken by some to indicate that the source of contamination of the Ottawa water is not the general condition of the river but is after the river water enters the intake pipe.

Ottawa, Ont.—A peculiar accident necessitated the temporary closing of the Booth Lumber Mills. The flume which carries the water for turbine driving became choked with sawdust and closed the supply.

Port Arthur, Ont.—The local newspapers publish a report of an interview with Sir Donald Mann, the Canadian Northern Railway regarding the steel works to be erected in this city. According to this report the investors joining the enterprise are sending out experts to gain first hand information on the project.

Toronto, Ont.—The municipal council will call tenders in a few days for the concrete and steel work in connection with Bloor Street Viaduct.

◆

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending July 8th, 1912:—

An English firm manufacturing liquid metal polish desire to introduce it to the Canadian market, and would like to hear from importers and agents.

From the branch for City Trade Inquiries, 73 Basinghall Street, E.C.

A Scottish company manufacturing soap and candles are looking for an energetic Canadian firm to handle their agency.

A London company manufacturing tar products, such as coal tar, pitch, creosote oil; and also disinfectants such as carbolic powder, pine fluid, disinfecting fluid, etc., wish to arrange for representation in Canada.

◆

PATENTS.

The following is a list of patents recently issued through the agency of Messrs. Ridout & Maybee, Manning Chambers, Toronto, from whom further particulars may be obtained:—

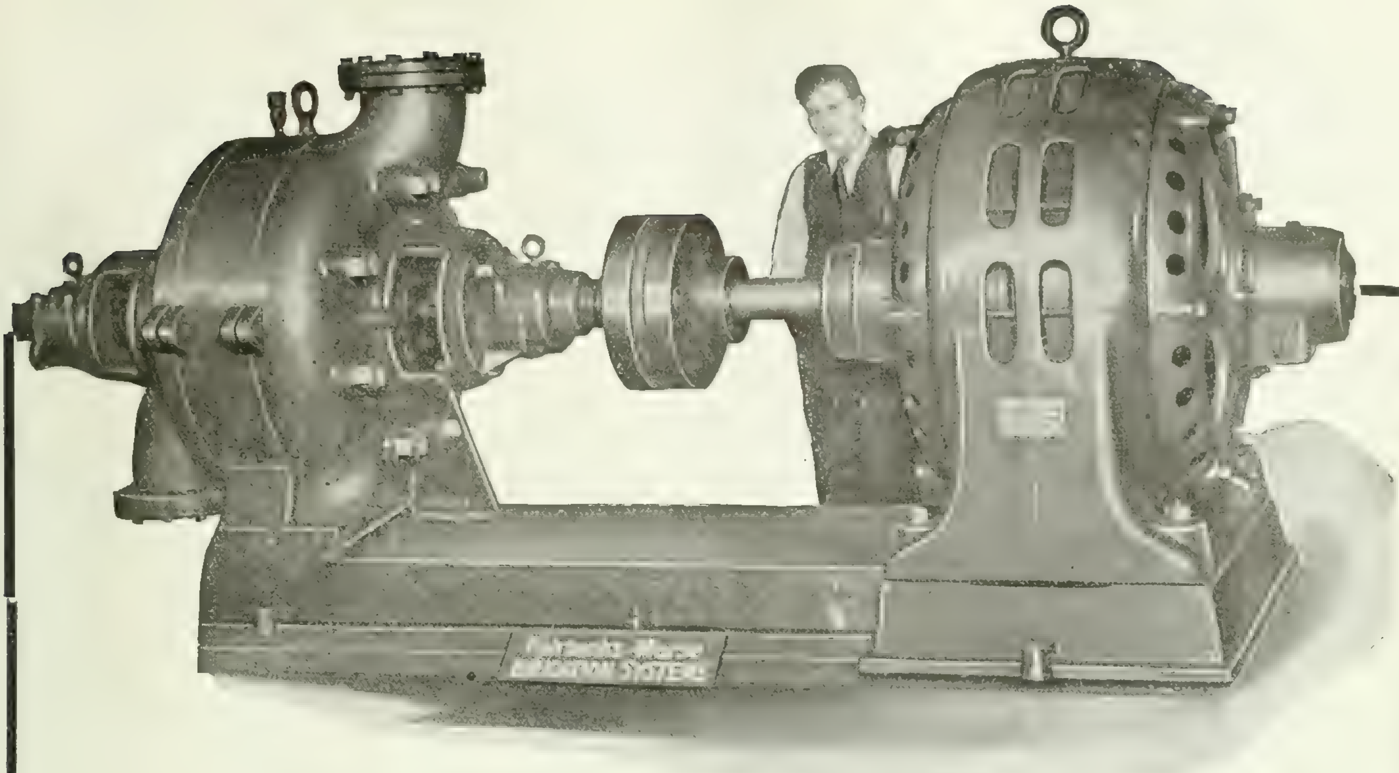
Canada:—G. G. Bell, electric cooking apparatus, (storage); Charles Caille, process and apparatus for heating steam or feed water (Case F); A. Brake and A. A. Dickson, molding machine; F. S. Henning and G. Murchison, chlorinating apparatus, (suction); Sydney Moody, saddle pillars and attachments for cycles; J. T. Drury, manually operated air pump.

United States:—A. D. [illegible], pencil sharpener; A. D. Welker, starting and stopping device for motor mechanism.

◆

PATENT FOR SALE.

Will sell Canadian rights and patents just issued on the [illegible] Rotary Pump. Most powerful pump manufactured for its weight and size. Extensively used in the United States, being adopted by the leading [illegible], breweries, creameries and for agricultural purposes. Low cost to manufacture. Simple in construction. Address inquiries to J. M. Crennan, Braddock, Pa.



The Largest Direct Connected Centrifugal Pumping Unit in British Columbia.

The Vancouver Power Company have recently installed at their works at Coquitlam Dam, B.C., the largest direct connected centrifugal pumping unit in British Columbia. This outfit is to operate in parallel with a number of other pumps that are to furnish water under pressure for sluicing into place the material for their new dam.

This pump is a 10-inch, class "F," two-stage centrifugal, with bronze inpellers and renewable bronze diffusion vanes. It has a normal capacity of 1833 imperial gallons per minute when operating at 1160 r.p.m. against a total head of 355 feet or an equivalent pressure of 154 lbs. per square inch. It is mounted on a common sub-base with a 300 h.p. type "B," Fairbanks-Morse squirrel cage, induction motor, 2200 volts, 60-cycle, 3-phase, 1160 r.p.m. at full load, being direct connected thereto by means of a flexible leather link coupling.

The motor possesses a feature in rotor construction that is unique. The end rings are welded on to the rotor bars by a new process, making a perfect joint, free from the troubles common to the purely mechanical or riveted joint, such as oxidation, working loose, and solder-throwing. This improvement marks a long step forward in the elimination of rotor trouble.

Our Vancouver Branch supplied and assembled this complete pumping unit. We are in a position to quote on the necessary equipment for any pumping requirements on receipt of specifications.

CALGARY, SASKATOON, VANCOUVER, VICTORIA.

A NEW WIRE CATALOGUE.

We have just received an advance copy of the new wire rope catalogue of the B. Greening Wire Company, Limited, and we feel that we must congratulate this firm upon the very handsome brochure they have issued. It is evident that no pains whatever have been spared in the production of the work. The very best paper procurable in Canada is used throughout. The cover which was evidently specially designed for this issue is in excellent taste and a very striking design. The color scheme throughout is gray and black. The illustrations are off the very highest grade of halftones, and the whole is bound with a fine silk cord which will no doubt make it very serviceable and avoid the annoyance so frequently experienced with trade catalogues in their falling to pieces after they have little use. The type used in the letterpress while necessarily small on account of the size of the book is fine and clear, and the whole production reflects the greatest credit not only up on The B. Greening Wire Company, Limited, but upon the designers and printers, The Reid Press of Hamilton.

The B. Greening Wire Company, Limited, issue different catalogues for their different lines of business. This new catalogue relates to their wire rope department. The first thing that strikes the ordinary man in looking at it is the great variety of wire rope that is used. Here we have wire ropes from the heavy 2¾-in. diameter (8⅝-in. circumference) composed of 114 wires with a breaking strain of 305 tons, weighing 12 lbs, per foot, down to the finest copper cord 1/16-in. diameter composed of 42 wires with a breaking strain of 100 lbs., weighing .007 lbs. per foot. We find in wire rope of ½-in. diameter there are no less than twenty-five different kinds listed. Wire ropes of varieus constructions from galvanized strand for guying purposes, composed of seven wires, to the extra pliable hoisting ropes composed of six strands of thirty-seven wires each with a hemp centre, or 222 wires, are shown, but in addition to the large variety of qualities and constructions of wire rope shown, The B. Greening Wire Company, Limited, frequently have to make up specially wire rope of an entirely different construction to suit special extraordinary conditions or circumstances, and their experts are at all times at the disposal of their friends for consultation or advice.

Our readers will understand by the above that this catalogue embraces practically every kind of wire rope that is at all likely to be called for and for almost any purpose—all kinds of hoisting, haulage, stay or guy ropes, drilling ropes, sand lines, ships' rigging, standing, running and hawsers, ferry ropes, sash cord of bright steel wire, galvanized steel wire, or solid copper, pliable tiller ropes with 252 wires such as used for clock weights, elevator hand ropes, vessel tiller ropes, and such purposes. Hay fork rope both for the track and running rope; railway ballast plow ropes, switch ropes, and separator ropes for threshermen and traction plowing, but in addition to the ropes there are a very large number of wire rope fittings and accessories such as blocks, pulleys, sheaves, wheels, turnbuckles, clevices, hooks, thimbles, rope grease and a very explicit description of splicing wire rope, but in many instances the greater value of this catalogue to our readers would be in the notes on how to care for and use wire [illegible] ving the best kind of rope to use for different purposes.

We strongly advise any of our readers interested in wire [illegible]

◆

MONTREAL WATER AND POWER COMPANY.

[illegible]

The usual table is given, showing the steady increase of the company since the gross revenue reached the sum of $100,000,000.

Years.	Gross Revenues.	Gross Increase.
1898-9	$160,922.01	
1899-0	177,922.01	$16,[illegible]69.86
1900-1	127,230.96	10,044.86
1901-2	140,816.66	13,579.70
1902-3	148,774.70	7,958.70
1903-4	165,826.96	17,052.26
1904-5	184,838.05	19,011.09
1905-6	213,668.07	28,830.02
1906-7	263,524.36	49,856.29
1907-8	300,836.83	37,312.47
1908-9	352,810.47	51,973.64
1909-10	388,112.10	35,311.63
1910-11	432,150.87	44,028.77
1911-12	506,504.13	74,353.26

A reference to the Profit and Loss Account will show that, after providing all operating expenses, including all cost of repairs, full maintenance charges and all general and legal expenses amounting to $228,900.30, the gross profit for the year amounted to $277,603.83. From the profits of $32,822.26, brought forward from last year, there was paid a dividend on the income securities of the company, leaving $5,957 35 to be added to the $277,603.83 gross profits of this year, or a total of $283,561.18. Out of this latter sum $132,575.02, being the net cost on operating account of interest charges, was paid, leaving a net profit of $150,986.16.

This balance was employed in further strengthening the various reserves of the company, as follows, namely; $32,912.20 was set aside to provide the year's proportion of the premium due at maturity on the outstanding bonds of the company and in meeting the year's proportion of the discount, etc., on the prior lien bond issue. The sum of $20,000 was provided for meeting possible bad debts, $65,000 was added to the general reserve account for depreciation, etc., and $1,897.22 for meeting special depreciation. This still leaves a balance of $31,176.64 to be carried forward.

The system of filtration has not progressed with the rapidity hoped for and construction work on the new reservoir has also been delayed.

About eleven miles of new mains were laid during the year, and this included the sinking of a 48-in. and a 36-in. main from the site of the new reservoir to the distribution system in the Laurier Ward. The total length of pipe in the entire system is now 157.61 miles, while the average size of pipe is 12.51 inches.

The intensely severe weather conditions of the past winter coupled with the lack of snow covering, resulted in the operating expenses of that period being largely increased. The frost was in the earth to a depth of about nine feet, and consequently there was an abnormal number of frozen services requiring repairs, and the pumping charges were increased owing to householders wasting large quantities of water to prevent further freezing within their houses. In this connection, it may be stated that the consumption of water per capita was the highest in the company's history, the increase over the preceding year being about 10 per cent.

TENDERS CALLED FOR

CITY OF WINNIPEG.

Tenders for Pipe Line to Poplar Springs.

Separate or bulk sealed tenders addressed to the Chairman, Board of Control, will be received at the office of the undersigned up to 11 a.m. on Wednesday, August [illegible]th, [illegible], for the supply of labor and materials required in the construction of a [illegible]-inch Pipe Line from Winnipeg to Poplar Springs (approximately [illegible] feet long). Alternative bids are invited for cast iron, sheet steel, and wood stave Pipe. Specification and form of tender together with conditions governing tenders as prescribed by By-law may be obtained at the office of the City Engineer, [illegible] James Avenue, Winnipeg. The lowest or any tender not necessarily accepted.

M. PETERSON,
Secretary.

Board of Control Office,
Winnipeg, July [illegible].

The Canadian Engineer

An Engineering Weekly

THE HIGH TENSION TRANSMISSION SYSTEM OF THE HYDRO-ELECTRIC POWER COMMISSION OF ONTARIO.

SECOND ARTICLE.

Insulators.—Suspension-type insulators are employed exclusively on the high-tension system. The specifications called for an insulator capable of withstanding an electric strain of 330,000 volts (three times normal) dry, 220,000 volts (twice normal) under a precipitation of ½ inch of water a minute at an angle of 45 degrees and a mechanical longitudinal stress of 8,000 pounds. The strain insulators employed to take up the horizontal strain on the cable were required to withstand a tensile load of 10,000 pounds without injury.

A number of insulator factories were visited before these specifications were prepared. Data was collected regarding methods of manufacture, and the facilities of the various manufacturers were investigated for producing insulators of the required quality in sufficient quantities. The data secured from the insulator tests carried out at the different factories was so varied that the commission decided to make independent comparative tests under similar conditions on the various types and three complete sample insulators called for with each tender.

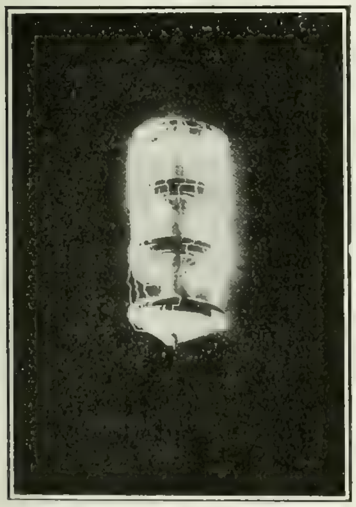

Fig. 12.—Insulators Under Test.

The insulator tests were made in the transformer station of the Ontario Power Company at Niagara Falls, Ontario. This company courteously offered the commission the use of all necessary apparatus, machinery and power, and during the tests assisted the engineers of the commission. The 330,000-volt dry test (Fig. 12) was performed in all cases. However, the 220,000-volt rain test constituted the real test of efficiency. The water was applied through a series of spray nozzles directed toward the insulators at an angle of 45 degrees. The flow was adjusted to give a precipitation of at least ½ inch a minute, which was called for in the specifications. The nozzles were arranged to subject all insulators to exactly the same conditions. These tests were performed in absolute darkness, and a large number of photographs were taken to compare the more or less vivid luminous display due to leakage and flashover. The mechanical strength of the sample insulators was also investigated and a large number of tests were performed to ascertain the ultimate breaking loads.

All tests were made entirely independent of the prices submitted in the various tenders, and the question of cost was not considered until after the final selection had been made, based on the above tests. As an evidence of the thoroughness of the tests and inspection of quality of manufacture, it may be mentioned that during the year and a half that the system has been in operation no interruptions have occurred through mechanical or electrical insulator trouble. An insulator of American manufacture was finally chosen after a few alterations in design had been made at the recommendation of the commission's engineers. The suspension type of insulator consisted of eight sections with a ball and socket connection, as shown in Fig. 13. The strain type consisted of ten reinforced sections with similar connections. These insulators were shipped assembled in crates to various railway sidings, and from there transported by team to the railway sites. The eight-section suspension-type insulators were used on standard towers. The ten-section strain type insulators were used on the line anchor, corner and long-span towers, and all special towers at railway, transmission line and navigable water-way crossings.

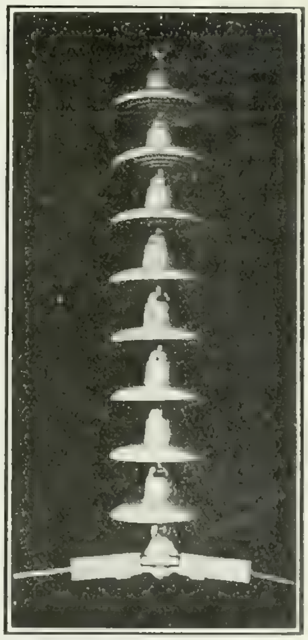

Fig. 13.—Standard High Tension Suspension Insulator.

The suspension type insulators weigh, assembled, about 100 pounds, and have an over-all length of 5 feet 2 inches, including the clamp. They are attached to the tower dross-arm by means of an eye-bolt, which is suspended from the tower arm by a galvanized U-bolt supplied by the tower contractor and placed in position by this assembling gang. The suspension insulators were hung by a gang of three men and a foreman, the insulator being raised to the arm by a line and pulley, the eye-bolt slipped into the socket in the cap of the top section and then keyed in place with a small cotter-pin. The greater portion of this work was performed in the winter and the rate of progress varied considerably, but under favorable working conditions, the gang could cover forty towers a day on single-circuit sections, three insulators to a tower. The strain insulators were not hung by this gang, but were delivered where required, and later erected by the cable gang.

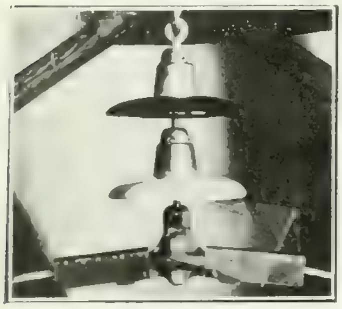

Fig. 14.—Standard High Tension Suspension Insulator Clamp.

The cable clamp employed with the standard suspension-type insulator is shown in Fig. 14. It was specially designed for this insulator and consists of a malleable-iron casting with supporting grooves and a bolted cast clip for clamping the cable. An aluminum sleeve of 1/16 inch plate surrounds the cable and serves to protect it from abrasion. The clamp for the suspension insulator is also provided with two galvanized sheet-iron shields, projecting over the cable at either end of the clamp and preventing burning of the cable by short-circuits occurring from the flash-over or failure of an insulator. All clamps and iron and steel parts are galvanized.

The strain insulator clamp, illustrated by Fig. 15, consists of two ¼ inch galvanized pressed-steel plates bolted together and provided with grooves to receive the cable. Aluminum sleeves and iron shields are also employed with these clamps to protect the cable from abrasion and burning. During the course of construction it was found advisable to place an order for a portion of the insulators with an European manufacturer, who furnished insulators of the same design and quality as those supplied by the American company. The total order [illegible] of the [illegible] the [illegible] of the [illegible] together with the necessary clamps, [illegible].

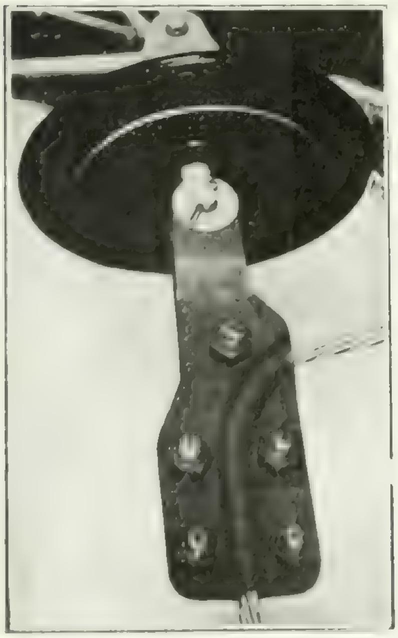

Fig. 15.—Standard High Tension Strain Insulator Clamp.

Cable.—[illegible] about three miles of copper [illegible] of Toronto, aluminum cable was used throughout the system. Two sizes were employed, No. 4/0 B &S gauge being used on the double-circuit line from Niagara Falls to Dundas, and No. 3/0 throughout the rest of the system. The cable was delivered on the field in reel lengths of 4,000 feet, and has the dimensions and characteristics specified in Table IV.

The cable gang consisted of twenty-five men, one foreman, one sub-foreman and two teams. The reels were mounted on portable frames and the cables run out three at a time by a team. As each tower was reached the cable was raised to the cross-arms and placed on wooden pulleys, suspended at the same height and adjacent to the cable clamps. When the cable on the three reels had been run out one span on each line was adjusted for sag by the commission's inspector, the sags on the other spans were allowed to adjust themselves over the pulleys.

The cables were then snubbed and men working on swings suspended from the arms removed them from the pulleys and clamped them to the insulators. While this was being done part of the gang with the sub-foreman and the other team worked in advance erecting ground cable. The ground cable is 5/16 inch, seven-strand galvanized steel, and was pulled up to the proper sag and clamped directly on the towers. On the double-circuit towers three ground cables are employed with two power circuits (Fig. 16) and two ground cables with one power circuit. The single-circuit towers are provided with a single ground cable.

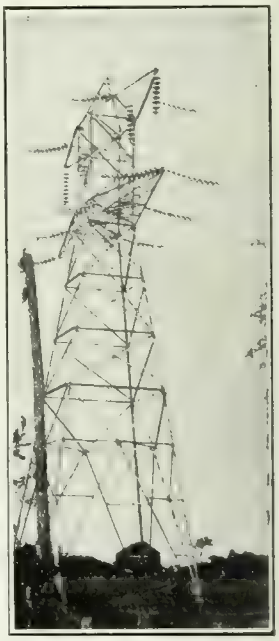

Fig. 16.—Standard Double-Circuit Anchor Tower.

Cable splicings (Fig. 17) were made by means of 18-inch and 22-inch aluminum McIntyre sleeves, the specifications called for sleeves providing for two and one-half complete turns. The ground cable splices were made by means of a specially designed connector. Cable sags were adjusted in the field according to sag tables which were compiled with reference to temperature and length of span. Calcula-

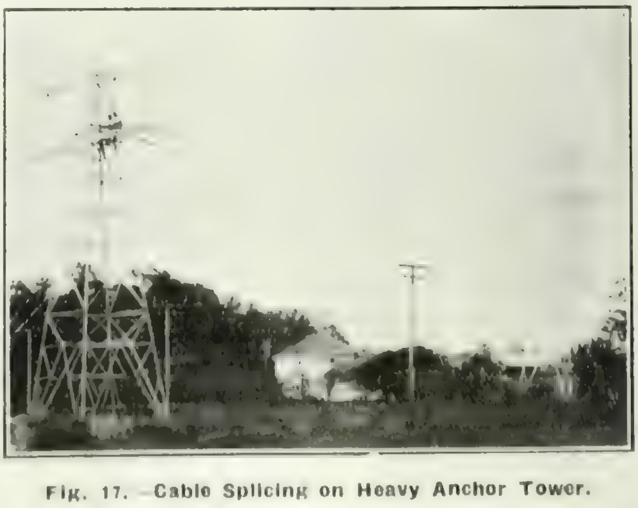

Fig. 17.—Cable Splicing on Heavy Anchor Tower.

tions were based on the assumption that the cables would be stressed to the elastic limit at 32 degrees Fahrenheit with a 3/8 inch coating of ice and a 65-mile gale. The minimum ground clearance allowed was 20 feet.

The rate of cable erection varied greatly, depending not only on weather conditions and topography, but upon the number of railways and transmission lines encountered. (Fig. 18). The erection of strain insulators and the forming and adjusting of loops on anchor and crossing towers seriously affected the progress of the work on some sections of the line. On double-circuit sections, where six power cables and three ground cables were erected, the average rate of erection was from ½ mile to 6/10 mile of the completed line a day. The labor cost varied from $110 to $215 a mile, the average being $130 for a mile of completed line. The rate of erection for three power cables and the ground cables was from ½ mile to ¾ mile of line a day, and the labor cost averaged about $80 for a mile.

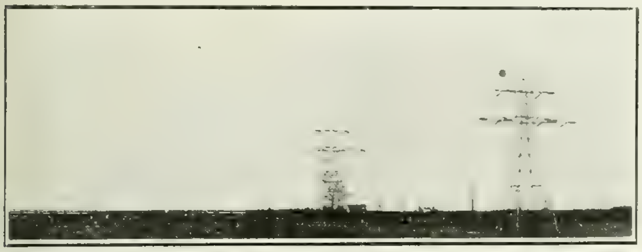

Fig. 18.—Typical Double-Circuit Transmission Line Railway Crossing.

Special Construction.—The most important special construction is located within the corporate limits of Toronto, where the high-tension line (Fig. 19) is carried to the Strachan Avenue station. This section of line is supported on towers giving 70-foot minimum ground clearance, and for a distance of about a mile the towers are located in Lake Ontario, 200 feet from the shore. Reinforced-concrete piers, cross-braced with steel girders 15-feet above water-level and protected at their bases by heavy hand-laid rip-rap support the tower bases.

HOW CITY PLANNING BILLS ARE TO BE PAID.*

By Nelson P. Lewis.†

In discussing city planning there is frequently a disposition to ignore such practical questions as that which is the subject of this paper. The writer recalls one occasion at a public dinner when a gentleman of distinguished reputation in the world of art expressed his sense of humiliation that one of the speakers, who was the chief financial officer of the city, should have introduced such sordid considerations as those of cost when the discussion up to that time had been confined to things of beauty. He assured his hearers that when, a few centuries ago, the men of Sienna or Florence wanted to do something to adorn their cities, they did not stop to consider the cost but went ahead and did it and thought about the expense afterward.

In contrast with this a prominent officer of a real estate holding company recently expressed his strong disapproval of any widening of streets or readjustment of street lines which was calculated to facilitate traffic, whether vehicular or pedestrian. He admitted that such changes might be advantageous to the city at large and would stimulate the development of outlying sections, but as his company owned a large amount of business property in the older part of the city, he believed that the rental value of that particular property for retail shops would be greater if the movement of the people were so obstructed that they would be compelled to loiter, to look into the shop windows and go in and buy.

We may have less patience with the latter than with the former point of view, yet both are inimical to real progress in city planning. He who scorns any consideration of cost may by his enthusiasm succeed in committing the city to projects which will seriously cripple its finances for years to come and render the public suspicious of any improvement, while he who openly avows his supreme selfishness may possibly arouse a feeling of indignation which will result in bringing about the very things he would like to prevent.

The question of how the bills are to be paid is not only a pertinent but a necessary one and cannot be avoided. To provide for a city of 100,000, with no apparent reason for exceptional growth, an ambitious scheme suited to a metropolis of several millions is to invite disaster; while to limit the plan of a large and rapidly growing city occupying a strategic position to one suited to its present size will seriously retard its future orderly development and may prevent it from realizing the growth and importance of which its natural advantages appear to give promise.

The feeling is common and not unnatural that if we are planning more for the future than the present, future generations which will reap the benefit should bear the greater part of the burden. It seems easy to pay with borrowed money, particularly when the money can be borrowed for fifty years or the span of two generations. The habit of paying in this way is easily acquired and is broken with difficulty. When anything is paid for with money borrowed for a period longer than the possible or even probable life of the article purchased, the city's credit is improperly used. A corporation which pays for its betterments from earnings is on a sound basis. When large earnings are used to pay excessive dividends and betterments and renewals are paid from borrowed money representing additional obligations, there is danger. When interest on existing debt is paid from funds raised by incurring more debt, disaster is imminent.

---

*Paper presented at the Fourth National Conference on City Planning, Boston, Mass., May 27-29, 1912.

†Chief Engineer, Board of Estimate and Apportionment, New York City.

The only source of revenue of the American city is its power to tax. Its credit is due to this same power plus the value of its own property. The larger the city's debt which has been incurred for projects which are not self-sustaining, the greater will be the demands upon its taxing power to meet interest and sinking fund charges due to such debt, and the less will be its ability to undertake new improvements and at the same time meet the enormous running expenses of the modern city. It might not be a forced comparison to say that the ordinary service which the city renders to the public through its administrative departments, the expenses of which are met by the regular tax levy, are the dividends which it pays to its stockholders, while for its betterments it must issue bonds or levy special assessments. Every bond issue requires an increase in the tax levy for a term of years in order to meet interest and amortization charges, curtailing by just so much the amount which can be expended upon municipal housekeeping expenses. In order to keep the tax rate within reasonable limits, expenses which should properly be met from the tax levy are often paid with borrowed money. Is not the city which adopts this policy actually doing the same thing as the business corporation which incurs additional debt in order to pay dividends?

The class of improvements which are commonly considered city planning projects are not self-sustaining. They consist for the most part in the correction of defects due to lack of proper planning. The property affected by them has presumably been already assessed for the acquisition and improvements of streets which were at the time considered adequate for its local needs. The widening and rearrangement of streets in built-up sections will, however, improve conditions and increase values, and a part of the expense should, therefore, be placed upon the property benefited.

In the more fundamental work of city planning, where unoccupied territory is being developed, the property will not have been assessed for improvements, and consequently the cost of the acquisition and construction of new streets can properly be assessed upon the adjoining property according to benefit, such benefit representing the entire cost in the case of local streets and a portion of the cost in the case of thoroughfares of metropolitan importance.

One principle should be invariably recognized, namely, where there is local benefit there should be local assessment. There can be no improvement which has been intelligently planned and executed without some local benefit, and it follows that there should always be some local assessment. No [illegible] to taxable val[illegible] the benefit. [illegible]

Perhaps this statement should be qualified [illegible] city planning. If so, the definition of city planning needs re-[illegible]

[illegible] The cost of that part of the subway passing through the districts where this rise in values took place was about $13,000,000, while the cost of the entire subway from the Battery north was $43,000,000. It is quite evident that if the $13,000,000 which was spent upon that part of the subway traversing the district so notably benefited had been assessed directly upon property, its owners would still have netted a neat profit of some $67,000,000, while had the cost of the entire subway been assessed upon the same limited district, the net profit to the land owners would have been $37,500,000. Was it quite fair that property in distant parts of the city, entirely unaffected by this great project, should bear the same proportion of the burden as that which was so conspicuously advantaged?

It is true that this improvement is entirely self-supporting, interest and amortization charges being provided from the rental paid by the operating company, but the local benefit was so clearly established that the rapid transit law was so amended as to permit the assessment of any part of the cost of future subways. Many new subways are now being planned, and some are being built, but it is doubtful if any of them will be self-supporting for years, the route furnishing the most intensive traffic having been followed by the line first built. The property owners along the present operating line having secured their benefit without direct tax, those along the proposed lines are not enthusiastic about being assessed for theirs, and there seems little prospect that the right to assess will be availed of.

To take another illustration from New York: Two new court houses are about to be built, one in New York County, the other in Kings County. In the former case a site has been selected to include a large area which will provide sites for still other public buildings and result in the creation of a real civic centre. What will be the effect upon the neighboring property of the expenditure of the millions required for this site and buildings? There is abundant evidence to justify the prediction that its value will be doubled, if not trebled, by the time the first building has been completed. Is is fair or just that the owners of this contiguous property should be enriched through no action of their own and that they should bear the same proportion of the expense, according to their taxable values, as will those owning property ten miles distant?

It needs no extended argument to prove the equity and wisdom of local assessment wherever there is local benefit. That it has been done to such a limited extent in the past is no reason why it should not be more generally done in the future. That certain property owners have heretofore been treated with such prodigal liberality is no good reason why others should fatten through a continuation of an irrational and essentially unfair policy. To the degree that the assessment plan is adopted, to that same degree will the city place itself upon a cash rather than upon a credit basis.

It may be urged that the adoption of such a policy would discourage the agitation for and execution of many desirable city planning projects, that American cities have been slow to appreciate the advantages of intelligent city planning, and now that there has been a marked awakening it would be unwise to suggest the adoption of a policy which might dampen this new born enthusiasm. A desire for something which involves no direct cost is not a sign of intelligent interest. We are learning that the improvement of our cities pays. That is a hopeful sign. If we have finally reached the stage where we want better conditions only if someone else is to pay the bills, the hope has not a very substantial basis. If we want them badly enough to pay for them ourselves in proportion to the benefit we feel sure will follow, we are making real progress.

Assuming that a case has been made in favor of assessing the cost of all improvements in accordance with prospective benefit, we are still confronted with a very difficult problem. The direct and indirect benefit must be estimated in advance. We cannot first carry out our city planning schemes and afterwards determine how the cost is to be met. Furthermore, we must determine to what extent the benefit will be strictly local, in what degree it will extend to a larger tributary area, and, again, how much it will mean to the entire city or metropolitan district.

In the case of residential streets, the purpose of which is to give light, air and access to the dwellings located upon them, the benefit will be entirely local, and the entire cost can properly be imposed upon the abutting property. When a highway is given a more generous width in the expectation that it will be called upon to accommodate a certain amount of through traffic, the benefit is more extended, and the assessment in such a case may be prolonged to a line midway between it and the next street of more than residential width. The major part of the cost should, however, be confined to the abutting property, so that the cost to it shall be somewhat more than that of the narrower street. In the case of arterial thoroughfares, or in that of the first street to be opened through an undeveloped territory the effect of which will be to give access to and stimulate the development of a large area, the district of benefit will be correspondingly enlarged. Again, in the case of thoroughfare of exceptional width, which it is proposed to treat as boulevards, the entire city or metropolitan district will be substantially benefited and should bear a portion of the expense. In fact, the state itself may derive an advantage which would justify its assumption of a portion of the cost, but the disposition to recognize such an obligation on the part of the commonwealth is exceedingly rare, even though a great city within its limits may, through its large taxable values, contribute the larger part of the state's revenues by which its rural highways are maintained.

In the case of parks this same principle might be applied. Some small parks are of strictly local benefit, and their cost could properly be placed upon the district in which they are located. Every park, whether small or large, is of some local benefit, even if such benefit were deemed to consist solely in unobstructed light and air to the property on the surrounding streets.

In the case of street widenings or the cutting through of new streets, the local advantage is less marked, though it will always follow. The mere fact that a widening or extension is required to accommodate traffic is conclusive evidence that the street has assumed more than local importance. The width of the roadway as widened is not an index of its local or general importance. There may be cases where the opening up of a new street of a width commonly given to local streets and extending for a very short distance would, on account of its strategic position, be of very great general and of little local benefit.

It is quite apparent that the relative local, district or general benefit of any street or other improvement can be determined neither by its dimensions nor its cost. An improvement involving an expenditure of $1,000,000 in one part of the city may be more distinctly local in its beneficial effect than one costing $5,000 in another section. No fixed rule can be established to govern the distribution of the expense. It must be determined in each case after a painstaking investigation. Such investigation should not be entrusted to a different individual, board or commission in each case. There should be a permanent body which should act in all cases. This body should not be large, and it should be so constituted that its entire personnel could not be changed at once, thus insuring continuity and consistency of policy. They should be broad men whose training should have fitted them for their difficult and delicate duties. The misleading evidence commonly called expert testimony as to existing and prospective values will be of little value to them. They should be capable by experience and intelligence of forming their own conclusions.

While no definite rule can be adopted to govern the distribution of assessments representing the district and general benefit, it should be possible to prescribe a method of determining the amount and extent of local benefit, particularly in the case of new streets, boulevards and parks. Let us assume that 60 ft. is the normal width required for a local street; then the entire cost of acquiring and improving all streets 60 ft. or less in width may properly be placed upon the property within half a block on either side of the street. In the case of wider streets that proportion of the cost represented by the ratio which 60 ft. plus 25 per cent. of the excess over 60 ft. bears to the width of the street would probably be an equitable proportion to assess upon the local district.

Inasmuch as property fronting a wide street is more valuable, it would be manifestly unfair to adopt a rule which would result in making the cost of a 70 or 80-ft. street less to the abutting owner than would have been the cost of a street 60 ft. wide. On the other hand, after a street reaches certain proportions, additional width will not involve additional benefit. It may be assumed that a share of the expense which would be equivalent to paving for a street 80 ft. wide should represent the limit of local assessment. This limit would be reached under the rule proposed when the street becomes 140 ft. wide. The percentage of cost which would be locally assessed would, therefore, be as follows for various street widths: 60 ft., 100 per cent.; 70 ft., 89.3 per cent.; 80 ft., 81.25 per cent., 90 ft., 75 per cent.; 100 ft., 70 per cent.; 120 ft., 62.5 per cent.; 140 ft., 57.1 per cent.; 150 ft., 53.3 per cent.; 200 ft., 40 per cent.

In the case of parks the problem is more difficult, the amount of local assessment and the extent of the area of local benefit being determined by the size and shape of the park and facility of access to it from other parts of the city. In any case, no rule should be adopted until it has been carefully tested and it has been demonstrated that the assessments levied in accordance with it will constantly decrease with the distance from the improvement. This decrease should not be directly in proportion to the distance, but in geometrical ratio.

A curve to determine the distribution of the assessments after the limits of the district have been decided has been proposed by Mr. Arthur S. Tuttle, Assistant Chief Engineer of the Board of Estimate and Apportionment of New York City, in accordance with which about 32.5 per cent. of the assessment would be placed upon the first 10 per cent. of the distance to the outer limit of the area of benefit, 55 per cent. upon the first 25 per cent. and 80 per cent. upon the district extending half way to the boundary of the assessment area.

In the case of street widening involving the destruction of buildings, it is suggested that the same general principles be adopted as in the case of new streets, but that they be applied to the land values only. If the street were less than 60 ft. wide, the proportion of the expense for additional land in order to make it 60 ft. would be assessed upon the half block on each side, while for all excess over 60 ft. the same rule already proposed could be adopted.

For instance, if a street 50 ft. wide were to be widened to 80 ft., involving the acquisition of 30 ft. of additional property, the first 10 ft. required to make it 60 ft. and 25 per cent. of the 20 ft. over 60 ft., a total of 15 ft. or one-half of the cost of the additional land to be taken, might be assessed locally, the expense involved in damage to buildings included in the district assessment, or in the general assessment if the improvement were of sufficient importance to involve general benefit. If the same street were to be widened to 100 ft., the local assessment under the same rule would be for 20 of the 50 ft. to be acquired, or 40 per cent. of the total land damage, the damage to buildings, as before, being included in the district or general assessment.

Special cases would undoubtedly arise which would require special treatment, but it is probable that in the great majority of improvements the method proposed would result in an equitable distribution of the burden. Those who are to pay the bills have a right to know in advance how the costs are to be apportioned, and the formulation of a policy which can be consistently followed is not only desirable but necessary.

The problem of determining whether or not there is general benefit and the proportion of the cost representing such benefit will be difficult. A typical case is that of a new boulevard recently laid out in the city of New York and now being acquired. It has been given a width of 200 ft. and extends from one of the great bridges over the East River directly across the Borough of Queens to Jamaica, and it is expected that it will ultimately be carried to the ocean front. It will afford ready access not only to the highway system of the Borough of Queens, but to all of Long Island. It includes within its lines an existing highway about 80 ft. in width.

Owing to its strategic position, this boulevard will be of more than local benefit. It was thought proper in this case to assess upon an area extending 800 ft. on each side that proportion of the cost of acquiring title represented by increasing the existing highway from 80 to 100 ft. Of the remaining 100 ft. it was decided to impose three-eighths upon the Borough of Queens and five-eighths upon the city at large. This division would have placed upon the local area, the borough and the city 16.7 per cent., 31.2 per cent and 52.1 per cent., respectively, but these were rounded off to 20 per cent., 30 per cent. and 50 per cent.

In the improvement of this highway it is proposed to construct one central driveway 41 ft. wide, with parking spaces [illegible] ft. wide on each side, and outside of these side roadways 28 ft. and sidewalks 20 ft. in width, the side roadways and walks to be treated strictly as local improvements and assessed directly upon the abutting property, and the central driveway and parking spaces to be treated as a part of the park system and to be built at the expense of the [illegible]. It is believed that such a distribution of the expense is just, but there has been a disposition to consider it a precedent for similar treatment in the case of other streets where the general public benefit would be far less, while in [illegible].

[illegible]

through recoupment by the exercise of the right of excess condemnation where this right exists, but this subject is to be treated in another paper, and is simply referred to in this connection.

Where the financial condition of the city will permit, the burdens of the property owner can be considerably lightened by the recognition of deferred benefit and a correspondingly deferred assessment. In this case the city would carry the amount until the benefit resulting from the improvement should have been fully realized, or, in other words, should have been reflected in actual increase in values. Similar relief could be given by permitting the payment of assessments in installments carrying a moderate rate of interest. Either plan would require larger capital to finance such improvements, and would to that extent impair the city's borrowing capacity for other purposes. These however, are matters of detail and have to do with the matter of collection of the assessments, rather than the distribution of the expense.

The general principles which should, in the writer's opinion, govern the distribution of the cost of city improvements, may be briefly summarized as follows:—

1. Where there is local benefit, there should always be local assessment.

2. The entire city or the metropolitan district should bear no part of the expense unless the improvement is in some degree of metropolitan importance and benefit.

3. Assessments should not be confined to the cost of acquiring and improving streets, but should extend to any improvement which will increase the value of the neighboring property, and should be apportioned as nearly as possible according to the probable benefit.

4. A workable policy once adopted should be consistently adhered to.

5. The determination of a policy and its application to each case should be entrusted to a board composed of men especially qualified, whose terms of office should so overlap as to insure continuity of policy and purpose.

◆

A LARGE REINFORCED CONCRETE BOAT.

A very large reinforced-concrete boat has recently been built for the use of the Manchester Ship Canal Company in England. This boat is described in the June 14, 1912, issue of London "Engineering." From that account we have made the following abstract:—

The boat in question is known as a sludge pumping pontoon. It has been built for the purpose of enabling dredged material to be deposited on low-lying land anywhere along either bank of the ship canal. The pontoon will be towed by steam tugs to selected points and there moored. The hopper barges will then be towed from the dredges as they are filled and moored alongside the pontoon. The suction pipe of the pontoon will be lowered into the barge to be discharged and the delivery pipe will deliver material upon the area selected for its reception. The pontoon is equipped with its own boilers and engine for the pumping operation described. It is 100 ft. long by 28 ft. wide, and [illegible] ft. 6 in. deep from the keels to the main deck, drawing about 6 ft. 6 in. of water when fully loaded. Its entire construction, including four water-tight bulk-heads and fittings for the boilers and engine, is of reinforced concrete. The pontoon was built according to the Hennebique system by the English agents of that system, Messrs. L. G. Mouchel & Partners.

A LARGE RETAINING WALL FOR THE CANADIAN PACIFIC RAILWAY IN TORONTO.

The Canadian Pacific Railway some time ago purchased from the Ontario Provincial Government the Government House property, located at the corner of King and Simcoe Streets, Toronto. This land is to be used for freight terminals and, therefore, had to be connected by track with the rest of the system lying south of Front Street. Two tracks of the Toronto Street Railway Company run along Front Street at an elevation of about twenty feet above the level of the tracks of the Grand Trunk Railway. It was, therefore, necessary, in order to connect the tracks at the lower level with the Government House property, to run along the south side of the street railway tracks on Front Street, and to protect these tracks by means of a retaining wall. Fig. 1 shows the location of the retaining wall along Front Street and an elevation of the wall itself. The wall at Bathurst Street is the highest section and at Spadina Avenue, about 2,100 feet east, the wall vanishes. Fig. 2 shows a typical section of the retaining wall at its greatest depth. Figs. 3 and 4 show the wall at different points. The wall is surmounted by an iron fence. Fig. 5 illustrates a typical detail of the fence posts used. The contractors were not allowed to interfere with the traffic on the Toronto Street Railway Company's line, nor to disarrange the north track of the Grand Trunk Railway. Excavation for the retaining wall was made with a Harris excavator. The excavator at work may be seen in Fig. 6. The

forms were located, steel and concrete put in, and the backfill placed before the excavation was made on the south side, next the Grand Trunk track. Fig. 7 gives a general view of the location, showing the street railway tracks on the left.

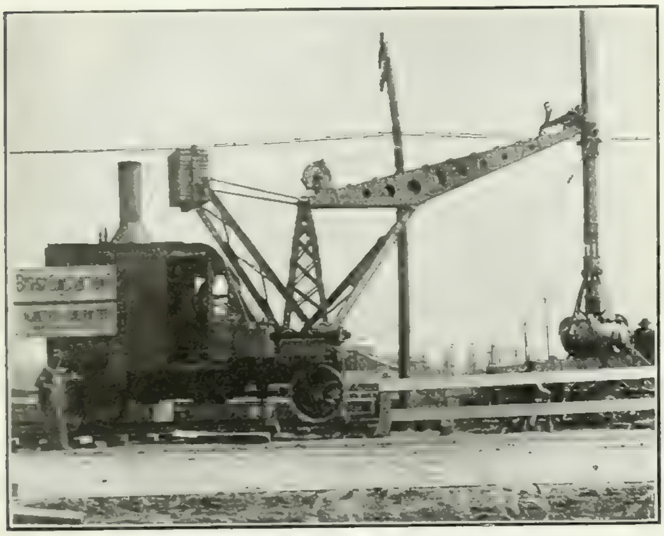

Fig. 6.

The foundations of the wall are carried to a depth sufficient to be absolutely free from frost, and stone backing was provided behind the wall. The contractors for the work are the Bishop Construction Company; the resident engineer in charge for the C.P.R. is Mr. C. S. Hertzberg. The wall was designed under the direction of Mr. P. B. Motler, engineer of bridges for the C.P.R.

FIXED AND TRAVELLING SEWAGE DISTRIBUTORS.

To determine the relative cost of sewage disposal with fixed sprays and with travelling sprinklers, Mr. Reginal Brown, engineer of the Southall-Norwood Works, England, prepared estimates for plants of both types. His findings, summarized below, were presented recently in a paper before the Association of Managers of Sewage Disposal Works.

The author decided to adopt a unit for comparison of eight 80-ft. diameter percolating filters, on which special revolving sprinklers were to be used, and an equal area of rectangular filters, on which fixed sprays were to be used, and to consider each installation to be working under the same conditions.

One of the great advantages attaching to the use of fixed sprays, and one which Mr. Brown has always advocated, is the complete breaking up and aëration of the liquid before it reaches the surface of the bed, which, without going into the chemical point of view, must be advantageous not only to the ultimate purification, but also to the life and work of the bed itself; hence, if revolving sprinklers are to be compared with fixed sprays they must be so arranged as to give the same effect, i.e., they must be subjected to a sufficient head and provided with a type of jet which will break up the liquid into a fine spray.

It is, of course, certain that the greater the head on the sprinklers the greater the distribution area per jet, and for comparative purposes a head of [illegible] ft. at the point of distribution was assumed. In most cases this would necessitate the lifting of the effluent water in the fixed spray type, but as this would also be the case in the revolving-sprinkler type, it is fair to assume that, in both cases, sufficient head is obtained without pumping. To get correct comparative results as to cost, each system of distribution should be provided with means of control into the same number of units; for the case under review this number would be eight.

Revolving Sprinklers.—The unit under discussion is eight 80-ft. circular beds. The ground is assumed to be level with the top of the carrier surrounding the beds. It has, therefore, been considered necessary that 6 in. of ground must be excavated over the whole area of the beds themselves, and 12 in. under the carrier. The base of the bed is constructed of concrete 6 in. thick at the periphery and 9 in. in the centre.

The beds are provided with 12 x 12-in. aërating and drainage tile. A ring of tiles is placed all round the outer edge of the circle, another and concentric ring is placed 20 ft. from the centre, while a third concentric ring is placed at 2 ft. 6 in. from the centre. The outer circle is divided into 3-ft. spaces, and at every fourth space lines of tiles are run to the inner circle, while at the intermediate spaces tiles are laid to the intermediate circle only.

The filtering medium is hard and well-burnt clinker, the outer walls being constructed of large lumps of clinker carefully bonded together and tied in to the filling. Over the drainage tiles a layer of large broken material is placed to a depth of 6 in., and the remainder for the whole height is filled with graded clinker and finished with a 3-in. layer of finer material over the whole surface.

The distributing system includes an 18-in. cast-iron pipe which commences at the boundary of the land occupied by the beds, and is carried to a brick control chamber constructed at the centre of the area. From this point 6-in. cast-iron pipes are carried under the beds and brought up through the concrete base by means of easy bends.

Each distributor is bolted to a concrete block 2 ft. square and 12 in. thick. The distributor consists of a central standard, a sealed top to utilize the full pressure due to the head, and to prevent overflow the mercury seal has been adopted. The distributing arms, four in number, are supported by means of strained guy ropes attached to a central tube carried up from and connected with the central standard, the top of the tube being pierced to allow for the escape of air. Each arm is pierced with thirty-five holes, spaced so as to give equal distribution and to permit of the breaking up of the liquid into a fine spray. Each hole is provided with a screw plug, pierced with two small holes inclined outwardly toward each other, so that two fine jets of water are discharged from each hole, and which meet at a short distance, thus creating a fine spray.

Fig. 7.

The cost of the sprinkler beds was $20,500. The area of land required is 6,525 sq. yds., which at $625 per acre is $815. The actual area covered by the eight beds is 5,044 sq. yds. The total external area of walls exposed to the air is 1,118 sq. yds.

Fixed Sprays.—To give a fair comparison, the area of the rectangular bed should be exactly similar to that of the eight circular beds; and, further, the means of distribution should be such as to control one-eighth of the whole area as a separate unit. The clinker area of the eight 80-ft. circular beds being 4,464 sq. yds., a square of 200-ft. sides has been selected, and a channel 3 ft. wide is constructed round the whole square. As in the case of the circular beds, the ground is assumed to be level with the top of the carrier. It has, therefore, been considered necessary that 6 in. of ground must be excavated over the whole area of the bed, and, to give about the same cross-fall to the concrete, the thickness of concrete at the centre will be 12 in. The carrier is, as before mentioned, 3 ft. wide inside, and its highest point is on the side opposite the outlet; this length is 400 ft., and to give the same fall as in the circular channels, commencing at a depth of 3 in. at the highest point, the depth of the carrier at the outlet will be, say, 12 in. Thus the depth of excavation for the carrier will be 1 ft. 6 in. The carrier has walls and bottom of concrete. The bed is covered with drainage tiles, arranged with a complete course round the exterior edge of the square, and straight lines of tiles are taken from this outer course towards the diagonals, drawn from each corner of the bed. The filtering media and external walls are similar to those described.

The following is a description of the distributing system. An 18-in. cast-iron pipe commences at the boundary area, and at the centre of one of the sides of the square a brick control chamber is constructed, as for the circular beds; 6-in. cast-iron pipes are taken from this control chamber to a point opposite to the centre of each unit, into which the whole bed is divided, and are continued upwards and over the drainage carriage, on to the edge of the bed. The bed is divided into eight units—seven being 24 ft. wide and one being 32 ft. wide.

The cost of the fixed spray system was $20,300 The area of land required is 4,922 sq. yds., which, at $605 per acre is $615. The total external area of walls exposed to the air is 445 sq. yds.

Annual Cost.—The total annual cost is made up of repayment of principal and interest on land and constructional work, and cost of labor and maintenance. For the land, in both cases it may be assumed that a loan would be granted for sixty years, and for the constructional works thirty years, but for the revolving sprinklers—as machinery—the loan would be for fifteen years only. For calculation these periods are taken, and the interest to be paid is 3½ per cent.

For the revolving sprinklers the capital cost is $21,330 and the annual cost $1,560. For the fixed sprays the capital cost is $20,900 and the cost per annum $1,440.

Effect of Spray.—In an 80-ft. revolving sprinkler Mr. Brown has found that with a head of 4 ft. there is a travel—at the periphery of the circle—of 8.4 ft. per second; there is, therefore, an intervening period of 7½ sec. before any part of the circumference of the circle receives a second dose of liquid. With the fixed sprays, however, the whole area of the bed is not, theoretically, covered by the spray, which takes a circular form. The area covered, however, depends upon whether the jets are spaced 8 ft. apart, vertically and horizontally (on plan), or whether they are spaced with the centres in the form of an equilateral triangle, each side of the triangle being 8 ft. In both cases, with a head of 4 ft. at the nozzle, the maximum diameter of the circle covered by the spray may be taken to be 8 ft., and the area of such a circle would be 5.58 sq. yds. If the sprays were spaced 8-ft. centres horizontally and vertically on plan, the total area per nozzle would be 7.11 sq. yds.; hence, an area of 1.53 sq. yd. is not covered. If spaced in the form of a triangle, the total area per nozzle would be 6.15 sq. yds.; hence, an area of .57 yd. would not be covered. Assuming the number of nozzles to be 625—arranged on the latter principle—the actual area covered by the nozzle would be 3,487½ yds., and, as the area of the bed is 4,464 yds., the area not actually covered is 976½ yds. super., or about 22 per cent. If spaced in triangular form, the actual number of sprays which could be fixed on the bed is 726, and the area not covered by the spray would be reduced to 10 per cent. of the whole area, but the cost of construction would be increased by $60 for nozzles only.

From Mr. Brown's figures it will be seen that a difference only of $120 per annum is in favor of the fixed-spray principle, but it must be borne in mind that this is obtained by the sacrifice of 22 per cent. area of bed not covered by sprays, no rest being given to the actual space covered by jet, if continually at work, and a very large reduction in area exposed to the air.

The chief reason for the excess of cost, although slight, of the revolving sprinklers over the cost of fixed sprays is due to the loan for the former being granted for fifteen years only. If the loan was for thirty years—as in the case of the fixed sprays—then the excess would be reduced to the infinitesimal sum of $25 per annum.

THE USE OF COPPER-SULPHATE IN PURIFYING WATER SUPPLIES.*

By Geo. Embrey, F.I.C., County Analyst, Gloucestershire.

In the year 1870 the author had frequent opportunities for observing the evil effects of plant growth in the artificial lakes of Sutton-Coldfield, Warwickshire. These were used as fishponds and for pleasure boats, but the growth of weeds was so extensive as to render them almost useless. Attempts were made to destroy the weeds by fixing scythes to the bottom of a punt and dragging this through the water, afterwards removing the weeds by means of rakes. This method was very costly, and not very effective, but in 1872, in the construction of a railway between Sutton-Coldfield and Walsall, an embankment which passed over the end of one of the lakes was constructed with ferruginous sand, and this, washing into the lake, effected in one season what the cutting method had failed to accomplish in seven; the vegetation was entirely destroyed, and this particular pool (Blackroot Pool) was effectually cleared of weeds.

On coming to reside in Gloucester in 1873, the author observed the bad odour and color of the drinking water, and on enquiry was informed that this was due to plants growing in the reservoir. He at once suggested the use of ferrous-sulphate to the city surveyor, Mr. R. Read, and an experiment was made on one of the reservoirs. About this time some trouble arose at a tannery due to oxide of iron from rusty pipes staining the skins red; this being wrongly attributed to the iron used in the reservoir, the experiment was discontinued, and for many years the weeds were removed by rakes at considerable expense without any satisfactory result.

The establishment of Bell's filters in 1901 to a considerable extent overcame the difficulty, but the author's attention was at that time directed to the reports of experiments made by the United States Department of Agriculture with copper-sulphate, which seemed to be an effective remedy. In the course of that year some watercress beds were treated with copper-sulphate, which was found to destroy the algæ, especially spirogyra, without injuring the watercress. In 1904 and 1905 numerous investigations were made to determine the amount which could be used for the destruction of the lower forms of plant life without destroying the fish or rendering the water toxic to human beings. It was found that quantities of 1 to 1,000,000 fulfilled these conditions, but quantities of 1 to 3,000,000 were sufficient to destroy the algæ, which were believed to cause the trouble.

---

* Paper read before Institution of Water Engineers of Great Britain.

In 1908 permission was given by the Sanitary Committee to carry out an experiment at Witcombe reservoirs, which were at the time choked with Chara Vulgaris. This plant is propagated by means of spores contained in an archegonium, and, fertilized by antheridia from an antheridium, the bursting of the archegonium sets free myriads of minute greenish cells, which, with the countless anthrozoids, give the water a distinct color and a fishy odour. In consequence of this odour it has been suggested that the particular chara was a new species named Chara Fœtida, but the author does not find that the plant differs in any material respect from the well-known Chara Vulgaris, except in regard to the odour. This, however, was removed by washing the plants, and an examination of the washing water revealed the presence of numerous Spongilla fluviatalis, which gave out a distinctly fishy odour. A portion of these was used to inoculate a nutrient agar medium, which, on incubation, yielded Proteus Vulgaris, a microbe well known to evolve a "fishy" odour, and the author, therefore, believes that this, and not the much-maligned chara, is the cause of the odour.

Method of Application.—The author's method of applying the copper-sulphate differs from that usually adopted, which is to place the crystals in a canvas bag and trail this at the stern of a moving boat. The defect of this method is that the copper-sulphate solution is very much diluted before reaching the bottom of the reservoir. This, however, is overcome by scattering the fine crystals over the surface of the water, as in sowing seed, the crystals falling rapidly to the bottom before dissolving. The sulphate is used in [illegible]

The three reservoirs have capacities, when filled, of 60,000,000 gallons (No. 1) and 30,000,000 gallons each (Nos. [illegible]

[illegible]

[illegible]

poisoned, but owing to the removal of the vegetable food on which they live, and this view is supported by the result of an experiment made at the end of last summer, when, No. 3 Reservoir being nearly empty, the rest of the water was, with the sanction of the city surveyor, drawn off, and, the trout having been removed to No. 2 Reservoir, only a few starved roach were found remaining.

As regards the question, What becomes of the copper-sulphate? it has been suggested that it unites with CO_2, and becomes carbonate, but the author has been unable to find this salt. He has, however, noticed that the stones with which the reservoirs are partly lined become coated with the two oxides of copper, bands of red cuprous oxide being traced, which, after exposure, becomes black by oxidation to cupric oxide. After four years' experience the author can confidently say that the odour and color so frequently met with in reservoirs containing water collected from the upper lias and inferior oolite can be perfectly removed by the use of sulphate of copper, and that no danger need be feared if the operation be performed with care and under proper supervision.

SOME NOTES ON BAND CONVEYORS.

By F. Tissington.

(THIRD ARTICLE.)

Belt Conveyors Capacities.—It is hardly possible to give any definite information as to the relative capacities of conveyors, as the figures are liable to change, even when considering the same class of material. This variation is due to a large extent to the feed, and also somewhat to the size of the material and the speed at which it is carried. Something has been said about these points before, and if the general practice laid down in Table I. is adopted so far as the two latter conditions are concerned good results should be obtained. Table II. has been compiled to give a general idea of the capacities of these belts for various classes of material and in a general way these figures should be obtained if a continuous feed can be arranged, as the estimate is by no means excessive. If, however, the material is being dumped in parcels with intervals between, an allowance must be made for this and a corresponding percentage of the values in the table taken.

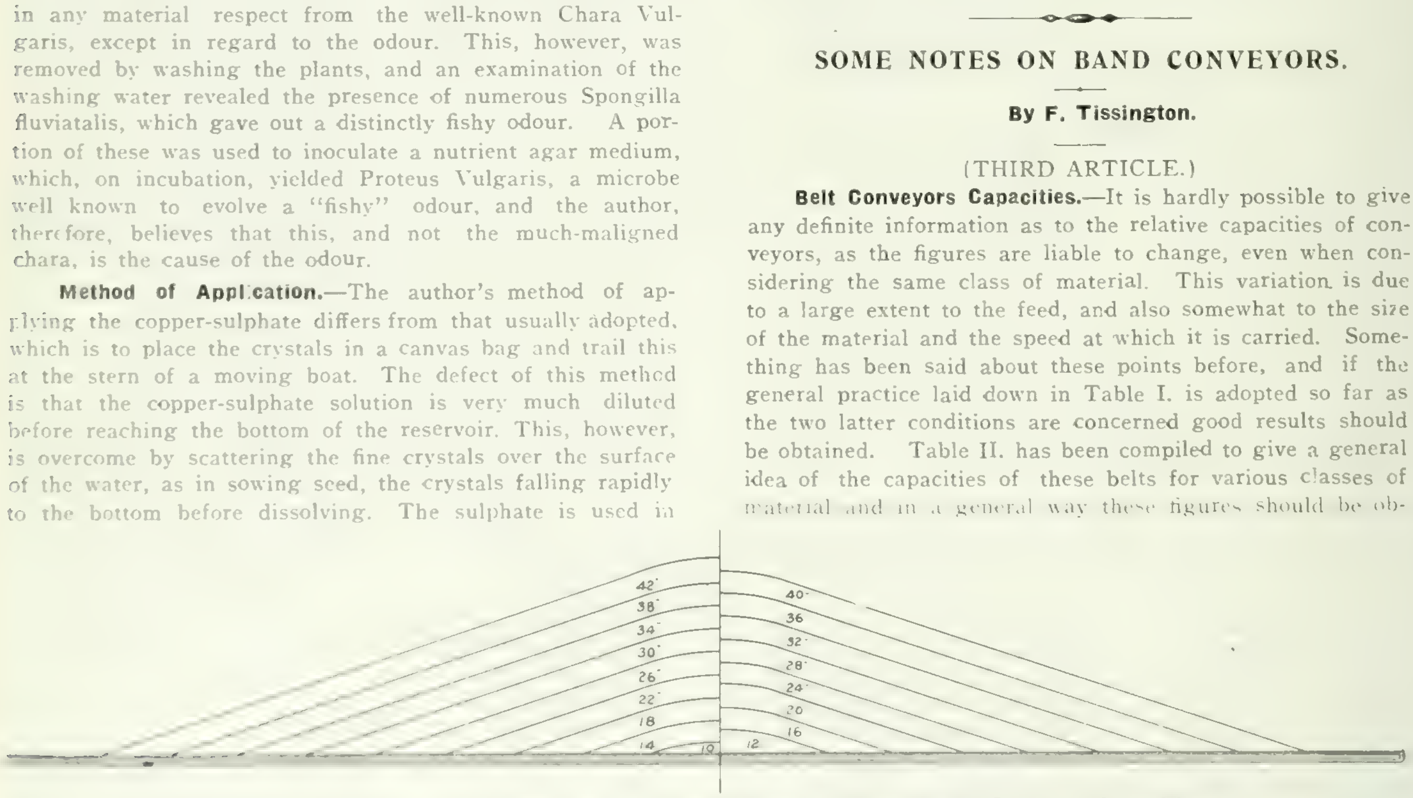

Fig. 16.—Cross Section of Belt Showing Approximate Carrying Capacities.

This table has been calculated on the assumption that the material loaded on the belt takes the form of a broad wedge in cross section with the two sloping sides at an angle of about twenty to twenty-five degrees with the horizontal. This will correspond roughly to the natural slope of the material, but naturally this varies with the different products carried. However, a clear edge distance of about three inches has been allowed for on each side of the belt which would prevent any spilling. The diagram given in Fig. 16 illustrates this, and in order to avoid confusion it has been laid out on a flat belt with a percentage added to allow for troughing.

Some further useful information is given in Table III., consisting of the weight in pounds per cubic foot and cubic inch, and also the amount of space occupied in cubic feet of one ton of material, and the number of cubic inches required to contain one pound weight of the same substance.

If any serious difficulty is experienced in obtaining the required capacity of a given belt it will be found that the addition of a special feeding apparatus suitable for the particular class will be necessary to increase same. In the case of large lumps, particularly if delivered onto a comparatively narrow band, some such arrangement will be necessary.

Horse-Power Required for Driving Band Conveyors.—It is a somewhat difficult matter to foretell exactly what will actually take place in any particular case, and why the only definite figures that can be obtained are those taken from an ammeter if the belt is driven by electric motor, and it therefore becomes a question for the designing engineer to estimate what power will be required from previous results.

A certain amount of power will be absorbed by the gearing and the belt itself when running light, and, as every engineer knows, the work on erection in setting all the parts up correctly and in alignment will have a great deal to do with the efficiency of the conveyor. In addition to this reverse bends in the band, such as are caused by the use of throw-off carriages, snub pulleys, etc., all require increased power over and above that necessary to drive a simple band of the same width and length, even if carrying the same material.

There are a number of different formulas, all claiming some particular advantage, some simple and some complex, and it appears to the writer that the only rational way of treating this problem is to select a set of rules that appear to be as near ordinary practice as possible and then make small allowances where necessary for special conditions.

The theoretical horse-power required to lift a given weight is $\text{H.P.} = \frac{W N}{33{,}000}$ where W = weight in pounds carried per minute and N = height in feet material is elevated.

Table IV. gives a series of values for this equation, the capacity ranging from 20 tons to 550 tons and the vertical life from 5 to 80 feet. These figures do not, of course, take into account any other factors, but simply represent the power necessary to elevate the load minus friction, efficiency of gearing, width of belt, etc.

For horizontal traction the force required must be some percentage of the figures given in Table IV. and the proportion will be regulated by the amount of friction to be overcome, both for the weight of the belt and for the full carrying capacity of same, the friction in the rollers and end gearing, etc.

Good average practice will be obtained if the percentage is taken at 20 per cent. on the maximum amount of the material which can be carried by the belt per minute. This allows for all losses for the moving parts of the conveyor itself except in the case of the smaller capacities, say from 150 tons per hour downwards, and for these an additional table giving values of the horse-power necessary for horizontal traction has been prepared. (See Table V.).

With the help of these two tables, it is now quite easy to estimate the power required to drive a belt conveyor of any ordinary type. If it is a horizontal one the figure can be taken at once from the table. Should there be any inclination in same all that is necessary is to add the figure for the latter to the former value and the sum is the total horsepower required. Note that the allowance for friction was made for horizontal traction and, therefore, in the case of an inclined conveyor no extra allowance for friction requires to be added to the figures in Table IV. for horse-power necessary to elevate the material.

NEW SPECIFICATIONS FOR CREOSOTE WOOD BLOCK PAVEMENT.

The Board of Local Improvements of Chicago, Ill., has lately gotten out new specifications for the construction of creosoted wood block pavements in that city. The new specifications differ from the old ones in a number of the requirements. The method of treating the timber is specified more fully and provision is made for the use of oil which shall be a distillate obtained wholly from coal tar. In addition the new specifications provide that an asphaltic filler may be used. The following is an extract of the specifications as far as they relate to the creosoted wood block wearing surface:

Blocks.—The blocks shall be cut from southern....... ......yellow pine, tamarack or southern black gum timber. Only one kind of wood, however, shall be used on the work. The blocks shall be not less than 5 ins. in length, nor more than 10 ins. in length, but shall average 6 ins. in length. The depth shall be............ins., and the width shall be .. ins.

All blocks shall be made of sound timber and shall be free from any defects which will be detrimental to the life of the block or interfere with the proper laying of the same. Each block shall have at least 66 per cent. of heart wood.

The blocks shall be carefully protected from the effect of the sun and weather before and after treatment and until laid.

Timber.—The timber shall be that known to the trade as "prime" timber and of a texture permitting satisfactory treatment as hereinafter specified, and shall be subject to inspection at the works in the stick or at any time during the process of preparation or thereafter. The timber shall be sound, square-edged, free from bark, shakes, large or loose or rotten knots, red heart, worm or knot holes, or any other defects which will be detrimental to its strength or durability. No second growth timber or loblolly pine will be accepted.

With southern...........yellow pine timber, the annual rings in the 3 ins. measured radially from the centre of the heart shall average not less than 8 to the inch.

When the timber for the blocks is only partially seasoned, the Board of Local Improvements may require the same to be piled in such a manner and for such a length of time as will prepare it for the treatment herein specified.

The Board of Local Improvements may at any time reject in bulk all timber that does not fulfill the above requirements, and order same removed and properly culled before being returned to the mill.

Treatment.—The blocks shall be placed in an air-tight cylinder, where, by means of steam and the vacuum pump, the sap in the blocks will be vaporized and the moisture in them removed. During the process of steaming a vent shall be kept open in the cylinder to permit the escape of water, [illegible] the cylinder. After the heating or steaming period, the drain or vent in the bottom of the cylinder shall be opened and all moisture removed from the cylinder. During the vacuum period the temperature in the cylinder must be above the boiling point of [illegible]

[illegible]

After the blocks are [illegible] the cylinder shall be filled with oil [illegible] and pressure shall then be applied and [illegible] pounds of oil have been forced [illegible] to the satisfaction of the Board of Local Improvements. The pressure period on the oil shall be continuous and of a duration of not less than three hours. After the surrounding oil has been removed, the blocks shall remain in the closed cylinder for a period of 30 minutes to allow the excess oil on the surface of the blocks to drain off. The oil thus drained off shall be forced back into the treating tank in order to determine the amount of impregnation. In the process of treating the blocks, a correction must be made for any water contained in the cylinder. Compensation shall also be made for leaks and other wastes of oil that may occur during treatment.

If, in the treatment of the blocks, more oil is injected per cubic foot of timber than is called for in the specifications, such excess oil must not be removed. The temperature of the oil after entering the cylinder shall not be lower than 165° F. The cylinder shall be provided with sufficient steam coils to fully maintain this temperature throughout injection.

The oil tanks and cylinder in which the blocks are treated shall be equipped with the necessary gauges, thermometers and draw-cocks in order to facilitate a thorough inspection of the materials and treatments. The cylinder shall be equipped with the proper connections and apparatus for artificially seasoning timber before the impregnation with the creosote oil.

The plant shall be provided with proper means for obtaining the absolute measurement and weight of all oils entering the cylinder and the amount of oil absorbed by the blocks.

Oil.—1 The oil shall be distillate obtained wholly from coal tar.

2. It is required by this specification that the oil used shall be wholly a distillate oil obtained only by distillation from coal tar. No other material, of any kind, shall be mixed with it.

3. The oil shall contain not more than 1 per cent. of matter insoluble in hot benzol and chloroform.

4. Its specific gravity at 25° C. shall be not less than 1.08 and not more than 1.12.

5. The oil shall be subject to a distilling test as follows:—

The apparatus for distilling the creosote must consist of a stoppered glass retort having a capacity, as nearly as can be obtained, of 8 ozs. up to the bend of the neck, when the bottom of the retort and the mouth of the off-take are in the same plane. The bulb of the thermometer shall be placed ½ in. above the liquid in the retort at the beginning of the distillation, and this position must be maintained throughout the operation. The condensing tube shall be attached to the retort by a tight cork joint. The distance between the thermometer and the end of the condensing tube shall be 22 ins., and during the process of the distillation the tube may be heated to prevent the congealing of the distillates. The bulb of the retort and at least 2 ins. of the neck must be covered with a shield of heavy asbestos paper during the entire process of distillation, so as to prevent heat radiation, and between the bottom of the retort and the flame of the lamp or burner two sheets of wire gauze, each 20 mesh fine and at least [illegible] square must be placed. The flame must be protected against air currents.

The distillation shall be continuous and uniform, the heat being applied gradually. It shall be at a rate approximately one drop per second, and shall take from [illegible] to [illegible] minutes after the first drop of distillate passes into the receiving vessel. The distillates shall be collected in weighed bottles and all percentages determined by weight in comparison with dry oil. When 100 grams of the oil are placed in the retort and subjected to the above test, the amount of distillate shall not exceed the following:—

Up to 150° S., 2 per cent.
Up to 210° C., 10 per cent.
Op to 235° C., 20 per cent.
Up to 315° C., 40 per cent.

The distillation of the oil shall be carried to 355° C. The residue thus obtained when cooled to 15° C. shall not be brittle but shall be of a soft, waxylike nature, so that it can be readily indented with the finger. When a small portion of this residue is placed on white filter paper and warmed, the oil spot produced, when viewed by transmitted light, shall appear of an amber color.

The contractor shall deliver to the Board of Local Improvements an affidavit from the individual manufacturing the blocks (if manufactured by an individual), from the managing officer of the corporation manufacturing the blocks (if manufactured by a corporation) and by an active member of the firm manufacturing the blocks (if manufactured by a firm), setting forth that all oil used for treating the blocks for this contract is a distillate oil obtained wholly and entirely by distillation from coal tar, and that it is free from any adulteration.

Oil.—The oil shall be a pure coal tar product, free from any adulteration. It must not contain any petroleum oil or any product obtained from petroleum, and shall contain not more than 5 per cent. of matter insoluble in hot benzol and chloroform. No oil obtained wholly or in part from water gas tar or oil tar will be accepted.

The specific gravity of the oil shall not be less than 1.10 nor more than 1.13 at 25° C.

[This oil is subjected to a distilling test similar to that for the first mentioned oil.—Editors.]

Laying.—The blocks shall be laid in parallel courses across the roadway at an angle of approximately.......... degrees from the centre line thereof, except at the intersections of all alleys, where they shall be laid at right angles with the centre lines thereof. On intersections and junctions of lateral streets, the blocks shall be laid at an angle of 45° with the line of the street, unless otherwise ordered by the engineer. The blocks shall be laid with the fibre of the wood running in the direction of the depth. Gutters shall be constructed as directed by the engineer. The courses shall break joints alternately by a lap of not less than 2 ins., and the blocks shall be driven together except where joints for expansion are constructed as follows: On each side of the roadway a longitudinal joint shall be formed by placing a 1½ in. board on edge against the curb. The blocks shall be firmly laid against said boards. The boards shall remain in place until the blocks are rolled, and immediately preceding the application of the filler as hereinafter specified, they shall be carefully removed without disturbing the adjacent blocks.

The blocks, when set, shall be rolled with a steam roller weighing not less than five tons, until firmly bedded and brought to a uniformly even surface. After rolling, all imperfect blocks shall be removed and replaced by perfect blocks. Broken blocks shall not be used except to break joints in starting courses and in making closures. If the blocks that have been laid should become wet before the filler is applied, they must be taken up and reset at the contractor's expense, if the engineer so directs. In no case will teams be allowed on the work before the wearing surface is completed.

Asphaltic Filler.—After rolling, the surface of the pavement shall be swept clean and the joints between the blocks and expansion joints shall be filled with an asphaltic filler which shall be free from water, coal tar pitch, or any product of coal or water gas tar. It shall adhere firmly to the blocks, be pliable at all climatic conditions to which it will be subjected, and conform to the following requirements:—

It shall have a specific gravity of not less than 0.965 at 77° F.

It shall have a melting point of not less than 110 and not more than 160° F.

It shall have a penetration of not less than 20 nor more than 50.

The bitumen of the asphaltic filler shall be soluble in carbon tetra chloride to the extent of at least 98½ per cent.

The asphaltic filler shall be heated to a temperature of not less than 280° nor more than 350° F., and shall be applied in such a manner that all spaces between the blocks will be completely filled, the temperature of heating to be varied within these limits according to the nature of the asphaltic filler used and at the discretion of the Board of Local Improvements. In applying the asphaltic filler care must be taken to use the least amount necessary to properly fill the joints and hold the top dressing. The blocks must be dry at the time of the application of the filler.

The contractor shall provide the Board of Local Improvements with a duplicate delivery ticket for each and every consignment of asphaltic filler delivered on the work. This ticket must be signed by the consignor, and be of a form approved by the Board of Local Improvements.

Pitch Filler.—After rolling, the surface of the pavement shall be cleaned and the joints between the blocks and expansion joints shall be filled with a "straight run" paving pitch obtained from gas house tar. No pitch from coke oven tar shall be used. It shall be of such quality and consistency as will be approved by the Board of Local Improvements. The pitch shall contain not less than 28 per cent. nor more than 35 per cent. of free carbon, and shall have a melting point at a temperature of not less than 145° and not more than 155° F. The pitch must be used at a temperature of not less than 300° and not more than 350° F. In applying the pitch, care must be taken to use the least amount necessary to properly fill the joints and hold the top dressing.

The contractor shall provide the Board of Local Improvements with a duplicate delivery ticket for each and every load or tank of paving pitch delivered on the work. This ticket must be signed by the consignor and be of a form approved by the Board of Local Improvements.

Cement Grout Filler.—After rolling, the surface of the pavement shall be swept clean, and the joints, except as hereinafter provided, between the blocks shall be filled with a cement grout filler composed of equal parts by volume of clean, sharp, dry sand and Portland cement, the same to be thoroughly mixed dry, after which water shall be added, forming a liquid of the consistency of thin cream. From the time the water is added until the grout is floated into the joints of the pavement, the mixture must be kept in constant motion, and immediately after applying to the pavement it shall be thoroughly swept into all the joints. The grout or filler shall be applied in two or more courses. The first course shall fill the interstices between the blocks to within 2½ ins. of the top, the same to be left undisturbed and sufficient time allowed to elapse for the first application to stiffen. The following courses or applications shall be mixed in like manner, except that the mixture shall be slightly thicker than that of the first course. To avoid a possibility of the grout thickening at any point, water shall be applied ahead of the sweeping by spraying.

The expansion joints and points between the blocks in a space of 2 ft in width adjacent to the gutters and around all covers to sub-surface improvements shall be filled with a "straight run" paving pitch obtained from gas house tar. No pitch from coke oven tar shall be used. It shall be of such quality and consistency as will be approved by the Board of Local Improvements. The pitch must be used at a temperature of not less than 300° and not more than 350° F. The pitch shall contain not less than 28 per cent.

nor more than 35 per cent. of free carbon, and shall have a melting point at a temperature of not less than 145° and not more than 155° F.

Sand Filler.—After rolling, the surface of the pavement shall be swept clean and the joints, except as hereinafter provided, between the blocks shall be filled with clean, warm fine sand, which shall be swept into the joints until the same are completely filled.

The expansion joints and the joints between the blocks in a space 4 ft. wide in the middle of the roadway shall be filled with a "straight run" paving pitch obtained from gas house tar. No pitch from coke oven tar shall be used. It shall be of such quality and consistency as will be approved by the Board of Local Improvements. The pitch must be used at a temperature of not less than 300° and not more than 350° F. The pitch shall contain not less than 28 per cent. nor more than 35 per cent. of free carbon, and shall have a melting point at a temperature of not less than 145° and not more than 155° F.

Top Dressing.—Immediately after the filling of the joints, the surface of the pavement shall be covered to a depth of ¼ in. with screened, hot, torpedo sand.

◆

THE DESIGN OF REINFORCED CONCRETE GRAIN ELEVATORS.

Certain of the problems that enter into the design of reinforced concrete grain elevators were discussed by Mr. E. Lee Heidenreich, in a paper read before the eighth annual convention of the National Association of Cement Users, from which the following notes are taken:—

Mr. Heidenreich states that the design of such structures is dependent entirely upon the nature and value of the pressure exerted by grain while at rest and in motion. Experiments and calculations to determine these values have been made by a number of well-known engineers, among whom are Mr. Janssen, Mr. Wilford Airy, Mr. Tolz, Mr. Prante, Mr. Jameson, of Canada, and Professor Milo B. Ketchum.

The last named states that the flow of grain is more like that of a semi-liquid than a liquid, with the pressure line forming a curve. According to calculations of Mr. Janssen and Mr. Jameson the lateral pressure may be expressed as:—

$$L = \frac{w R}{u}\left(1 - e^{[illegible]}\right)$$

and the vertical pressure by

$$V = \frac{w R}{C u}\left(1 - e^{[illegible]}\right)$$

[illegible]

If the circular bin is empty and the two opposite interstices A and B are filled, we have a condition which necessitates reinforcement both at the intrados and extrados of the ring.

Compression in the direction $A B$ causes tension at the extrados at C and D and at the intrados at A and B. From experiments in loading culvert pipe firmly supported at the two lower quarter points, corresponding to E and F, the maximum moment at the section may appropriately be written

$$M = (D / \sqrt{2} - 6)\ L'\ D'/64.$$

Computing the resisting moment in the customary fashion, the stress in the concrete and in the steel may be determined from the expressions:—

$$f_c = \frac{M}{K/2\,(1 - K/3)\,b\,d^2}$$

and

$$f_s = \frac{M}{p\,(1 - K/3)\,b\,d^2}$$

By adding 1 in. to d_1 or d_2, the ring thickness is found.

A calculation of the external pressure shows that the stresses from the filled interstices are greater than those resulting from the filled circular bins. To provide for this some contractors using single reinforcement in the centre bins have rodded the interstices, while others increase the thickness of the bin walls and the connection between contiguous circular bins.

According to Mr. Heidenreich, the logical method seems to be to use double reinforcement.

The calculation of square bins, he states, is a simple matter, after the lateral pressure L has been found. The bending moment will be in inch pounds $M = 12\ L\ l^2/10$ where l = width of bin in feet.

Mr. Heidenreich states that interior bin walls having alternately pressure on either side should be reinforced on both sides. The connection of the reinforcements at the intersections and the corners of the bin walls in such cases becomes of the greatest importance. Where possible he recommends employing a strong wire fabric as a part of the reinforcement for the outer walls, running this reinforcement horizontally around the building.

◆

SERIOUS OUTBREAK OF TYPHOID FEVER OCCURS AGAIN IN OTTAWA.

The alarming increase in the number of typhoid cases in the city of Ottawa has called for the immediate action of the authorities and other business has been temporarily thrust to one side in order to give all concentrated energy to this pressing matter.

Dr. J. W. MacCullough, chief health officer of the Province of Ontario, has made a personal investigation of the district including an inspection of conditions along the water front.

The cause of the contamination is due to a leak in a concrete well through which the polluted water entered.

The Provincial Medical Health Officer has ordered the City Council to have plans prepared for a new system of water supply, to consist of a mechanical sand filtration plant on Lemieux Island in the Ottawa River, to be connected with the pumping station in the city by a tunnel under the bed of the river to carry the intake pipe and keep it free from contamination. The estimated cost of the tunnel is $[illegible], while the plant will cost about $750,000.

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of the
CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, RAILROAD,
MARINE AND MINING ENGINEER, THE SURVEYOR,
THE MANUFACTURER, AND THE
CONTRACTOR.

RAILWAY BUSINESS FOR MAY.

For the month of May the net operating revenue of the railways of the United States declined five and five-tenths per cent. per mile of line as compared with May, 1911, and that for May, 1911, was four and eight-tenths per cent. less than for May, 1910. This is the salient fact of the monthly summary of the Bureau of Railway Economics, compiled from the reports of the railways to the Interstate Commerce Commission, and embracing ninety per cent. of the steam railway mileage of the country.

The total operating revenues were $226,109,262, an increase of $7 per mile of line over May, 1911. The operating expenses were $161,368,677, an increase of $24.29 per mile of line, while the net operating revenue was $64,740,585, a decrease of $17.23 per mile of line. Taxes amounted for the month to $9,897,301, or $45 per mile, an increase of nine and two-tenths per cent.

The decrease in net operating revenue was most severe for the Eastern group of railways, amounting to eleven and nine-tenths per cent. For the Southern group it increased four-tenths of one per cent., and for the Western group less than one-tenth of one per cent. The aggregate of the net operating revenue for the eleven months of the fiscal year, and also for the five months of the calendar year, when measured per mile of line, shows a decrease in comparison with the corresponding periods of the previous year.

◆

OTTAWA WATER SUPPLY.

The water supply of the city of Ottawa has again been the subject of discussion, as a result of another outbreak of typhoid. The Provincial Medical Health Officer in no uncertain manner has impressed on the city council the necessity for immediate action with regard to improvements in the supply. For some time the city engineer has been preparing plans for a slow sand filtration plant. The council had decided on this method of purification, although the experts who were called to report on the method, and the source of supply, had decided against it. The city engineer himself had objected to slow sand filtration, but his objections were brushed aside by the council. The Provincial Health Officer, however, refused to sanction slow sand filtration, and demanded that immediate action be taken towards installing a mechanical filtration plant.

In the seventeenth annual report of the Board of Health of the Province of Quebec, Mr. James O. Meadows, the sanitary engineer for the board, gives a report on a sanitary survey of the Ottawa River. His report presents many matters of interest, and has been published in a pamphlet form recently by the Provincial Government for general distribution. This report of the sanitary condition of the Ottawa River was undertaken to study the river as a source of domestic water supply and its relations to public health, and the information contained is based upon results secured from analytical data recently completed and by analytical data which was available from previous local studies. These studies relate to the potability of the domestic water supplies in regard to their relation to sewage, refuse, and industrial wastes discharged into the river at points above those from which such water supplies are obtained. These questions have been further studied by the aid of vital statistics and typhoid fever data so as to obtain their relations to the public health. The work has been confined to a study of the main river from a point above Pembroke to Montreal, and the main object has been to determine to what extent the Ottawa River is used as a source of public water supply.

This study has shown that the Ottawa River above the city of Ottawa is in a very satisfactory condition as regards bacterial purity, except where polluted for a short distance by municipal sewers. It is not probable that the amount of pollution for this district will increase perceptibly for a considerable period of time. The report states that because of the high color content of the Ottawa River water, mechanical filtration will be found to be the most satisfactory method to be adopted to secure a purified water of satisfactory physical appearance and bacterial purity.

In the face of their experts' report and the above investigation, conducted by the Quebec Board of Health, the council showed poor taste, to put it mildly, to order plans prepared for slow sand filtration, and the rebuke administered by Dr. McCullough was well deserved. On last Friday night the Ottawa Council decided in favor of a mechanical filtration plant, to be established on Lemieux Island, in line with Dr. McCullough's recommendations. Ottawa's experience is one more instance of the result of interference on the part of the city council in matters of which they know nothing, and which should be decided by engineers.

CANADIAN PACIFIC STOCK.

Accumulating money at a rapid pace, making continued increases in earnings, always enlarging its programme of construction and improvement, the discussion of another issue of stock for the Canadian Pacific Railroad will not be silenced. A member of a New York banking house with London connections is the latest to re-echo the belief that when Parliament meets again at Ottawa, the railway will apply for authority to increase the amount of its authorized common stock capitalization.

The authorized common stock of the company is $200,000,000, it having been increased from $150,000,000 at the stockholders' meeting in October, 1908. Outstanding on June 30th, 1911, was $180,000,000. Shareholders of record of January 2nd, 1912, were privileged to subscribe at 150 for $18,000,000 of new common (ordinary) stock to the extent of 10 per cent. of their holdings. This is now being paid for, and will have yielded $27,000,000 by the time of the last payment, viz., October 18th.

In some quarters it is asserted that the next bonus to stockholders will take the form of an increase in the regular dividend rate to 12 per cent., which rate, in view of the rapidly expanding earnings, could be easily enough sustained. Others still seem to hold to the belief that a plan will be formulated whereby the large extraneous assets of the company will be segregated from the railroad assets proper and new securities created to represent them. But the majority is anticipating a new issue of common stock at 150 or 165, with accompanying valuable "rights" accruing to shareholders.

"The circumstances giving rise to this expectation of new financing," says the New York banker, "are the extraordinary expansion of earnings and the fast-rising [illegible] of land. It is apparent to those who have a reasonably good acquaintance with the vast scale upon which Canadian Pacific operates, that in a comparatively [illegible] [illegible] [illegible] or more of new cash capital must be provided. When the time comes, some of the new capital [illegible] be had, through the issuance and sale of more 4 per cent. debenture stock and perhaps 4 per cent. preferred stock. But the greater part of the requirement will be obtained by issuing additional common stock."

The earnings of the Canadian Pacific for several years have consistently made new records, and it looks as though the current year will make still another. While no official decision respecting the double-tracking of the system from coast to coast has been announced, observers see that such an enterprise will become necessary in a comparatively short time.

If another offering of stock is made, say, $40,000,000, at 150, which was the price of the $18,000,000 issue of last January, it would yield $60,000,000, but, as there is a likelihood of the next block being offered at a higher price, probably 165, an issue of $40,000,000 would bring $66,000,000. Such an amount would serve to carry the company's programme forward on an increased scale for another year. The company usually has on hand a working cash balance of $45,000,000 to $50,000,000, and this amount, coupled with the newly raised capital—$27,000,000 through sale of common stock and about £1,000,000 of preferred stock in London at the close of last year—the company could put about $80,000,000 into the construction work it has under way without issuing any new stock. Ample amounts, however, must be provided from time to time for the proper operation of the company's system, not only to-day, but in years to come.

EDITORIAL COMMENT.

We have had occasion several times of late to refer to the request of the Chicago Drainage Canal Sanitary District for permission to divert more water. We are glad to note that the United States Secretary of War has decided against allowing any increased diversion. The Canadian Commission of Conservation, and its able secretary, are to be congratulated on the able manner in which the objections of Canada were presented. It was largely due to this energetic protest that the increased amount was not granted.

* * * *

The judgment of the Privy Council, just delivered, awarding a decision in favor of the Niagara Falls Queen Victoria Park Commission against the Niagara power companies, in the matter of power rentals, means much to the Commission and its policy of beautifying the Niagara Peninsula. The question was whether the companies should pay rental on a peak basis or on the average load, and the decision of the Privy Council reverses the previous judgment of the Canadian courts. It is of interest to note that the opinion voiced by Dean Galbraith, of the University of Toronto, some years ago, when called as an expert by the Park Commission, has been sustained by the Privy Council.

LETTER TO THE EDITOR.

Sir,—In your leading editorial in your issue of July 25th you refer to a recent article of mine which you entitle "Mining and the University." The article referred to was one of a series being published in the Canadian Mining Journal, and in Applied Science, and the title was "The Mineral Industry and the University of Toronto." In this particular case, this is a distinction with a difference. The choice of terminology happens to be exceedingly vital.

H. E. T. HAULTAIN,

306 Stair Building, Toronto.

THE PRODUCTION OF CHLORINE FOR WATER AND SEWAGE STERILIZATION.

By Joseph Race, F.I.C., (Toronto Filtration Plant.)

Chlorine is being so largely used at the present time for the treatment of drinking water and sewage that a review of the different methods used in its production will be of general interest. Almost the entire quantity used at present is made either from bleach or by the electrolysis of brine solutions, and as the latter are becoming more prominent, they will be described first.

Electrolytic Methods.—When electricity is passed through a solution of common salt, the sodium chloride molecule is dissociated and the components liberated. If these are not separated, the chlorine combines with the sodium hydrate formed by the action of the sodium on the water present, to form sodium hypochlorite, a strong germicidal agent. There are two types of electrolysers used for the process . In one, the cathodic and anodic products are allowed to recombine in the main body of the electrolyte; and the other, the diaphragm process, the products are removed separately from the cell as produced. For the production of sodium hypochlorite, the non-diaphragm process has usually been adopted because it dispenses with the destructive diaphragms and the loss of energy that such diaphragms cause. Dr. Rideal of London, (England), has recently developed a cell of this type with an energy efficiency of 68 per cent., but as complete data are not available, the non-diaphragm process only will be dealt with.

The theoretical voltage required for the decomposition of sodium chloride is 2.3, but when the products recombine in the electrolyte, side reactions occur which raise the minimum voltage to 3.54. On this basis one kilowatt gives 272 amps., and as one amp. hour is theoretically capable of producing 1.28 grams of chlorine, 1.26 kilowatt hours are necessary for the production of 1lb. of chlorine by the decomposition of 1.65 lbs. of salt; this represents an energy efficient of 100 per cent.

Charles Watt (1851) was the first to patent this process and to recognize the necessary conditions, which are: (1) Insoluble electrodes; (2) Low temperature of electrolyte; (3) Rapid circulation of electrolyte from cathode towards anode. The temperature is very important, for, if it reaches over [illegible]° C, oxidation takes place, and the efficiency is lowered. The following types of electrolytic cells are now in use in various places:—

The Haas and Oettel Electrolyser.—The latest form of this electrolyser makes use of carbon as electrode material and of the liberation of hydrogen at the cathode to effect automatic circulation and mixing of the liquid in the cell. The inner or working cell is a rectangular stone-ware tank divided by the carbons into 30 narrow compartments or cells, each of which has one hole at the bottom and two others at the sides about two inches from the top. The first and last carbons of the set form the main electrodes of the cell; the intervening carbons act as secondary electrodes, i.e., as anodes on the one face and cathodes on the other. This inner cell is supported on a brick foundation within a stone-ware tank measuring 72 inches by 36 inches deep and is filled with a 15 per cent. solution of brine to within four inches of the top. The carbons are protected at their top and bottom edges with slips of glass of the same width as the carbons, which prevent short circuiting due to dirt and sludge, and also prolonging the life of the carbons. A continuous current of 80 amperes at 100 volts is employed to work the electrolyser, and as soon as the electrical connection is made the evolution of hydrogen at the negative or cathode surface of the electrodes causes the level of the liquid within the cells to rise above the overflow pipes, and a rapid circulation of the brine occurs, fresh liquid flowing in at the bottom of the cells. The liquid passing away at the top of the cells flows over cooling plate, and when necessary the heat produced by electrolysis is further dispersed by aid of cooling pipes placed in the layer containing tank.

The following figures give the yields of the industrial type TE/3 of this particular electrolyser:—

Capacity—165 gallons of brine. Strength 15 per cent. Salt required (112 kilos) 247.5 pounds.

Current—75 to 80 amperes at 110 volts for 10 hours equivalent to 88 B.T. units.

Yield—165 gallons hypochlorite solution containing 14 grms. of free chlorine per litre (1.4 per cent.) equivalent to (10.5 kilos) 23.1 pounds of chlorine.

The carbon electrodes are reported to have a life of 18 months for a 10-hour working day, and to cost for renewal £3-10c.-0 per set. The labor required for operating this type of electrolyser is about one hour per day, as when once charged with fresh brine is can be left for 10 hours but with slight attention. The current efficiency falls from 95 per cent. to 52.8 per cent. during the 10 hours required to produce a solution containing 14.0 grms. of chlorine per litre (1.4 per cent.) the highest efficiency being obtained with a concentration of 2.5 grms. of chlorine per litre (0.25 per cent).

The Kellner Electrolyser consists of a shallow stoneware tank divided into a large number of narrow cells by means of vertical glass plates so arranged that the electrolyte is obliged to take a zig-zag course in its passage through the electrolyser. The electrodes are formed of platinum-iridium gauze, and are arranged horizontally with anodes below the cathodes, so that the chlorine liberated at the former may be absorbed by the supernatant liquid. This electrolyser has only two terminal electrodes, and all the intervening electrodes function as secondary electrodes as in the Haas and Oettel apparatus. The electrolyser is constructed usually to take a current of 110 volts. Brine is passed continually through the apparatus until the desired concentration is obtained, a small centrifugal pump being employed to circulate the brine through the electrolyser and an external cooling vessel being used to keep down the temperature below 25° C. Using a 10 per cent. solution of salt, the current efficiency falls from 87.5 per cent. to 45.8 per cent. in 10 hours, the free chlorine rising from 0.309 to 1.295 per cent. during this period. The following figures give the yield of the industrial type (2 Esn. 60/9) of this apparatus.

Capacity—820 litres (180 gallons) of brine. Strength 15 per cent. Salt required 123 kilos (270 lbs.).

Current—90 amperes at 110 volts for 10 hours, equivalent to 99 B. T. Units.

Yield—820 litres (180 gallons) of hypochlorite solution, containing 20 grams free chlorine per litre (2 per cent.), equivalent to 16.4 kilos (36 lbs.) of chlorine.

The life of the platinum-iridium electrodes is, of course, much longer than that of the carbon electrodes employed in the Haas and Oettel electrolyser, and their scrap value is considerable; but, on the other hand, they are not indestructible, and if the brine contains magnesium salts, the deposit of these cause trouble.

The Hermite Electrolyser.—The distinctive features of this cell and process are the uses of a mixture of sodium and magnesium chloride as electrolyte, of magnesium hydrate as a preservative, and of zinc as negative element in the cells. The electrolyte is prepared in an elevated tank, and is allowed to flow by gravity through a series of four double troughs. These troughs were formerly made of slate, but are now constructed of glazed earthenware, and each is divided by a partition which causes the electrolyte to pass twice along the length. Each division of the trough contains five sets of electrodes, two negative electrodes of zinc, enclosing one positive electrode formed by winding thin platinum wire upon a perforated porcelain slab of the required shape. There are thus six separate cells containing 40 pairs of electrodes in the one unit of plant, and a current of 15 amperes at 230 volts is employed, the electrodes and cells all being connected electrically in series. The electrolyte passes between each of the electrodes in its passage from the inlet to the exit, the flow from one trough to the next being controlled by glass syphons and funnels. A small addition of sodium hydroxide solution is made to the liquid as it flows from the last trough, glass carboys being employed to receive the mixed solution of calcium and magnesium hypochlorites. The capacity of each unit of plant is 185-200 gallons of solution at a strength of 4 to 6 grams. of chlorine per litre (0.4 to 0.6 per cent.) per eight-hour day, the rate of flow of electrolyte being 3 1-3 pints per minute. The first unit of plant was erected at Poplar in 1906, and cost with all the necessary accessories £583 ($2,915), the second unit erected at the beginning of 1910 cost £501 ($2,505). The running cost—electricity, water, chemicals, supervision and testing—for the half-year ending September 30th, 1910, amounted to $500 (£100), but this total does not contain any allowance for interest, depreciation, rent, or distribution charges. The net cost of one electrolyser [illegible]

The Vogelsand Electrolyser.—The original form of Vogelsand electrolyser resembled in its main construction features of Hermite and Kellner electrolysers, the electrolyte being made to take a zig-zag (vertical) course through a trough filled with a large number of electrodes (secondary). Lead plates faced with platinum on the anode side were used as the intermediate electrodes, and by varying the number of these the electrolyser could be made to take a current of 85 amperes at 65 to 110 volts. An electrolyser of this type was said to have produced 20 kilos (44 lbs.) of active chlorine in a 10-hours working day, equivalent to a yield of 1 kilo of active chlorine (2.2 lbs.) per 6.6 E.H.P. hours, or an energy efficiency of 35.8 per cent. The use of lead for electrodes did not, however, prove satisfactory, and the Vogelsand cell has been considerably modified. The electrolyser now worked at Nottingham and other places abroad is constructed with composite electrodes. Narrow bars of slate extending the full width of the cell are wrapped with a sheet of platinum-iridium foil in zig-zag fashion, the result being an electrode of great strength, which can carry high current densities, and presents opposing surfaces of foil where required. The sectional area allowed for carrying the current through the electrode (from one face to the other) should be proportioned to the superficial electrode surface in contact with the electrode.

The Mather and Platt Electrolyser.—This resembles that of Kellner and is constructed with [illegible] electrodes made of a platinum-iridium alloy, and with two terminal electrodes for connection to the current mains. The 40 cells into which the electrolyser is divided by plate-glass strips and so arranged that the electrolyte takes a zig-zag course, and attains a [illegible] chlorine, equivalent to 6 K.W. hours per kilo, or 2.7 K.W. [illegible]

The Dayton Cell.—[illegible]

Rickard's quarterly bulletin, Ohio State Board of Health, Oct.-December, 1909, states that with this cell one pound of available chlorine could be produced by the consumption of 2.65 K.W. hours and 6.9 pounds of sodium chloride. This result was obtained by cooling with ice. Without the cooling process, 3.62 K.W. hours and 7.2 pounds of salt were necessary. Other results with this cell are to the effect that one pound of available chlorine can be produced by the consumption of 3.38 K.W. hours and 7.7 pounds of salt. The cell (model T N) using 20 gallons of 5 per cent. salt solution per hour gave a liquor containing 0.65 per cent. of available chlorine by the consumption of 40 amperes at 110 volts.

Taking the results given in the above descriptions of the various forms of electrolytic hypochlorite cells, we obtain the following figures for the relative yields:—

Type of Cell.	Salt used. lbs.	K.W. hours.	Active chlorine. lbs.
Haas and Oetell	247.5	80 x 110 x 10 88	23.1
Kellner	270.0	90 x 110 x 10 99	36.0
Hermite	78.5	15 x 230 x 8 27.6	9.57
Mather and Platt	....	19.33 x 220 x 10 42.52	7.0
Dayton	100	40 x 110 x 10	13.0
Theoretical	1.65	1.26	1.0

Efficiency.

	Salt used.		Power used.	
	lbs.	per cent.	K.W. hrs.	Efficiency.
Haas and Oettel	10.7	15.4	3.80	33.2
Kellner	7.5	22.0	2.75	45.8
Hermite	11.2	14.5	2.87	43.9
Mather and Platt		....	2.75	45.8
Dayton	7.7	21.4	3.38	37.3
Theory demands	1.65	100	1.26	100

The cost of production will depend upon local circumstances. If alternating current is available at $30 per horsepower per annum, the price per K.W. hour of direct current, assuming the efficiency of a motor generator set to be 88 per cent., will be 0.52 cent. With low-grade salt at $5 per ton, the cost of one pound of available chlorine would be as follows:—

Cost of Pound of Available Chlorine.

Type of cell.	Salt.	Current.	Total.
Haas and Oettel	2.67	1.97	4.64
Kellner	1.87	1.43	3.30
Hermite	2.80	1.49	4.29
Dayton	1.92	1.76	3.68

From these results it is evident that the most efficient cells are the Kellner and the Dayton, but as the former involves a much larger capital outlay owing to the high cost of the platinum-iridium electrodes, the latter is the most economical cell available. Low-grade salt is often unsuitable for use in the Kellner cell owing to the magnesium salts depositing on the electrodes and reducing the efficiency.

Chemical Methods.—

(a)—Bleaching powder.
(b)—Sodium hypochlorite.
(c)—Liquid chlorine.

Bleaching Powder.—Bleaching powder (commercial calcium hypochlorite) on addition to water yields chlorine in an active condition, and this constitutes one of the simplest and most economical methods of producing chlorine for sterilization purposes. Bleach usually contains 37-38 per cent. of available chlorine, and of this about 33 per cent. is easily obtained by solution in water. The product of the new plant at Windsor, the only bleach plant in operation in this country, is sold at $25 per ton, so that each pound of available chlorine costs 3.75 cents.

Sodium Hypochlorite.—This compound is sold by Brunner Mond & Co., Northwich, England, under the trade name of "Chloros." In this country it costs 25 cents per gallon, and as the solution contains about 12 per cent. of available chlorine, each pound of chlorine costs approximately 20 cents.

Liquid Chlorine.—Anhydrous liquid chlorine has recently come into use for sterilization purposes, and its introduction in 1910 was due to Major Darnall, M.D., of the Medical Corps of the United States Army. The method is very simple, being the addition of dry chlorine gas, evolved by releasing the pressure on the liquid chlorine, to the water to be treated. Chlorine is obtained as a by-product in the manufacture of caustic soda, and a portion of it is purified, dried, liquefied by pressure, and put on the market in steel drums or cylinders holding 100 to 140 lbs. each. The chlorine thus obtained is almost chemically pure, the impurities being traces of oxygen, carbon dioxide, and nitrogen. The pressure of the liquefied chlorine on the walls of the drum varies from 54 pounds per square inch at 32° F. to 216 pounds pressure at 122° F. The price is approximately 12 cents per pound, but there is doubt that this will be very materially reduced if the consumption materially increases.

Relative Sterilization Efficiencies of Chemical and Electrolytic Chlorine.—The claims made for the superior bleaching efficiency of chlorine produced by electrolytic methods have been modified by the results of recent independent research, and it is now generally accepted that there is but slight difference (not exceeding 5 per cent.) between the bleaching effects obtained, if the chlorine be present in the same form of combination and in the same degree of concentration in the various bleaching liquors. The disinfection and bleaching properties of chlorine are both due to the nascent oxygen liberated on solution, so that the above remarks apply equally well to chlorine for disinfection purposes. It is probable that the carbonic acid content of the water to be treated is a much more important factor than the form of combination of the chlorine, as this is the constituent of water that is mainly responsible for the decomposition of the hypochlorite into hypochlorous acid and free chlorine which in turn produce nascent oxygen.

Capital Outlay.—The capital outlay required for chlorine treatment depends so largely upon individual requirements that generalizations on this phase of the subject are practically of no value. Whilst chemical chlorine is undoubtedly the best in an emergency or for temporary use, the electrolytic method is deserving of full consideration, where chlorination is decided upon as a permanent measure. At Baltimore and Cincinnati the electrolytic process was probably installed on account of the extremely low cost of electrical current, and where even the same conditions obtain, this method is undoubtedly the most economical.

Resume of Costs.

Electrolytic—				
Haas and Oettel	4.64	cents per	pound of	available chlorine
Kellner	3.30	"	"	"
Hermite	4.20	"	"	"
Dayton	3.68	"	"	"
Chemical				
Bleach	3.75	"	"	"
Sodium				
Hypochlorite	20.0	"	"	"
Liquid Chlorine	12.0	"	"	"

CONCRETE SUBSTRUCTURAL WATERPROOFING.*

By J. R. Wickle.

The cost of the proper waterproofing of a building bears but a slight percentage of the total cost of the completed structure, and architects and engineers have recognized the fact that the use of good materials, giving permanent results, are the only ones which they can afford to employ, if only as a matter of good economy. The use of pitch and kindred products is gradually being abandoned for the reason that such materials disintegrate when in contact with moisture and are affected by alkalies and other substances in the soil which rapidly destroy them. Therefore, it must be apparent that such materials should be used which are unaffected by the conditions peculiar to the foundation.

Two methods are open to the architect preparing his waterproofing scheme. The first is the membraneous or seal method, which consists in surrounding the entire foundation with an impenetrable envelope interposed between the structure and the water or moisture to be kept out. The "integral" method is that by which the waterproof agent becomes absorbed into and integrated throughout the concrete mass, or through the cement plaster, or concrete so completely as to render the mass, or plaster, impregnable to the attacks or penetration of water or dampness.

For your consideration we will first take up the membraneous system. Where the term "foundation" is used, it is understood to be that of concrete in accordance with the general practice. The matter of heads pressure, and so forth, will be referred to only in a general way, as the object of this paper is not to dwell upon the engineering features of the substructure, but to discuss the waterproofing systems used and employed in this connection. The conditions under which the work is to be done will, to a large extent, determine the method to be used. In considering the membraneous treatment let us assume that our footing course has been placed. The next step is to lay the waterproofing over the footings, using no less than three ply of good felt bonded by means of a good bitumen. Bitumens which require heating are the ones used most advantageously in this connection. Binders of the sort will remain relatively tacky, and will not crack or break, due to any subsequent settling ot the foundation. Having laid this damp course, the waterproofing will be carried up the outside of the foundation wall to six inches above the grade line. Where only ordinary seepage exists, the use of a heavy asphaltum damp-proof paint applied on such walls will be sufficient, but should the walls be left in very rough shape, a bituminous plastic which is applied with a trowel should be substituted for the liquid damp-proof paint as suggested above. This last treatment dispenses with the safety coat of cement mortar which is necessary as a protection to the waterproofing in back-filling on completion of the work. In placing the waterproofing over footings the felt should project at least six inches on either side of same in order to make connection with the waterproofing to be carried over floors and the exterior side of the wall. The floor waterproofing is laid between upper and lower beds of concrete, the concrete being laid in such a manner that the top bed of same will resist any hydrostatic pressure which may develop from below. To illustrate: Supposing the total thickness of concrete to be placed for floors is seven inches, a three-inch bed would first be placed on which will be laid the waterproofing, the same number of plies being used as laid over footings. Upon this three inches of concrete will be put, as an upper bed, and a one-inch top dressing of cement and sand, say 1 to 2 mix, to provide a wearing surface for the floor. This floor waterproofing is made continuous by joining the felt with six inches of same projecting from the footings and up the walls. The method is simple, but is not always permanent, except that you employ such materials as will be unaffected by the expansion and contraction of the foundation. The architect or the contractor will see that the connections are properly made as between the wall waterproofing and the floor waterproofing, for it is at this point that trouble usually develops. Irish felt is considered one of the best reinforcing agents for substructural waterproofing, and, to-day, materials of this kind which are on the market compare very favorably in price with the domestic paper, in fact I believe a number of imported felts to be cheaper. Where considerable pressure is to be met with at least six ply of felt should be installed. In many cases automatic pumps or ejectors are erected in connection with a sump pit in order to keep the water around the foundation below the floor level. This installation, however, is optional, for waterproofing done in a careful manner as I have outlined, with an eye to the selection of proper materials on the part of the architect, will be reliable in the most acute cases. Where ordnary seepage occurs, a stratum of a plastic bitumen can be substituted for the felt. If the foundation adjoins that of another structure it is evident that the felt cannot be placed on the outside of the foundation walls, without first laying up a brick wall on the outside of the bearing wall to sustain the waterproofing. In instances of this kind, it depends upon the conditions whether this scheme should be preferred to the integral method.

---

* Paper read before a meeting of Architects in Winnipeg.

Coming to the integral method, it is perhaps, well to touch upon the character of materials now largely in use. In the laboratory or in very careful practice, it is possible to obtain a voidless concrete by using properly graded aggregates with the cement. A concrete thus obtained is waterproof, but in every-day work, taking into consideration the human equation, the probabilities of securing an absolutely dense concrete, are too utopian for consideration in this paper. Owing to the porous nature of concrete, many tests have been conducted with the object of securing a medium to overcome this porosity with an absolutely voidless concrete at the ultimate. Some materials on the market are liquid in form, and we are advised they do not act as void fillers, but simply increase the cementative properties of the cement without affecting the volume of concrete and have for their object a closer relation between the cement and the aggregate. This is explained as bringing into service the full colloidal possibilities of the cement. Frequently hydrate of lime is used for the purpose of waterproofing concrete. It is my opinion that this is not a successful agent, unless the lime can absorb oxygen or slack. In plastering, for instance, the object of using three coats of lime mortar is to give the lime sufficient surface to take up oxygen and fulfil its purpose. Take a sixteen-inch wall, for instance, waterproofed by the use of lime; it will only be waterproof on or near the surface where the lime has the opportunity of becoming active. In the interior of such wall we find this agent in an unslacked state, having absolutely no chance to assist the cement, and is a loafer on the job. It will be seen that unless all parts of the mass can receive the full [illegible] of the [illegible] [illegible] that the purpose of the agent cannot be attained.

Experiments have been conducted in the laboratories of several of the large universities of the United States which [illegible] [illegible]. Other materials now in use act as [illegible] [illegible] [illegible] of [illegible] [illegible] and water- [illegible] [illegible] affecting the strength of the concrete, they [illegible] [illegible] [illegible]. Materials of this kind are [illegible] [illegible] [illegible] and are extensively used. A concrete mass so waterproofed will lose its capillary value for attracting water. Having selected the material, the next question to decide is, shall we incorporate it throughout the entire concrete body, or use it in an interior plaster coating? If we decide the former, all that is necessary is to put in the waterproofing when mixing the concrete, and the other details of construction can be carried on without further regard to the waterproofing except to observe the manufacturer's directions as to mixing and so forth, and leaving no part of the substructure untreated. The question is often brought up as to what assurance we have that the material be properly mixed. If the workman is not careful in mixing his concrete he will not secure a good concrete, and by the same token he will not secure a waterproof concrete. On the other hand, a careful workman will be as careful in adding his waterproof compound as he will in mixing his concrete. The fact that many perfect jobs executed by following manufacturer's directions and without his supervision, is a test to the merit of these waterproofing factors. The advantages of the integral method are quite apparent. No need to build a retaining wall to receive the waterproofing when building against an adjoining wall. Another service, and a great one, which the integral method performs is exemplified when trouble develops in a foundation. Excavating around the outside of foundation walls, and applying asphaltum, serves only to keep the water from the structure at that point, while it is a natural course for the water to find its way through the footings and floors. The best that we can expect from such a treatment is a waterproof wall down to the footings, and water will come up through the footings and floors. In other words, we must secure continuity of the waterproof course. The solution of the problem and the only practical way of obtaining such a continuous surface is an interior application whereby the waterproofing can be placed over all walls and floors, and thus successfully resist the penetration of water at all points.

In discussing the membraneous method I mentioned that the waterproofing would need to be placed between the water to be combatted and the structure, but in the application of the integral method as a plaster coating, this is not necessary. For the purpose of explanation, let us consider a concrete foundation with seepage occurring at different points. It is not possible to apply the waterproof coating as described, on a surface continuously wet and by water under pressure, so as in all problems in waterproofing, the first step will be to keep the water below the floor level during the process of waterproofing. One of the methods commonly employed for this purpose is known as "bleeding the wall"—that is, inserting iron pipes in the wall at points where the entrance of water is most apparent, these bleeders being placed so as to permit the pumping of the water from the outside wall to a point below the level of the surface to be waterproofed. Having done this, the next step is to make all surfaces to be treated sufficiently rough to receive the plaster coating. This can be done by hacking, followed by an acid wash, which, in turn, is washed off with clean water after the effervescence ceases. The use of acid (common muriatic acid) or acids in powder form used for this purpose act upon the lime in the cement and expose the silicate particles of the concrete. Then we apply our waterproof plaster coating, which is a coat of either 1 to 2 or 1 to 3 mixture of cement and sand, having the waterproof agent mixed in. This applied on the walls in a three-quarter inch coating and on the floors in a coating at least one inch in thickness, will accomplish the result after the waterproofing is set up; then it is possible to seal the bleeders. As to the adhesion between the waterproof coating and the concrete, this bond will resist any pressure which may develop. Many large jobs have been waterproofed by such a scheme as I have described. The waterproofing is ever in sight and the installation can be made on a brick foundation wall, with practically as good results as can be obtained on a concrete wall.

In conclusion, you yourselves can best determine the method to be employed based upon the local conditions. A suitable caption would be, suit methods to conditions and material to methods, and with this ever in mind, and without pre-supposing the nicety of workmanship guaranteed in ordinary labor, we are able to get good results.

HYPOCHLORITE STERILIZATION AT KANSAS CITY, MO.

By S. Y. High, Chief Superintendent of Water Works.

The water supply of Kansas City, Mo., is taken from the Missouri River about five miles above Kansas City, at the Quindaro station in Kansas. The water is pumped directly from the river into settling basins. The water is then treated with lime and sulphate of alumina. After leaving the basins through the back flow or suction pipe, the hypochlorite solution is introduced before the water gets to the pump, the pump agitation making a thorough mixture of the hypochlorite with the water.

From the Quindaro station the water is pumped to the Turkey Creek station twelve-million-gallon reservoir, and from this reservoir to the service mains.

Since the demonstration at Boonton, N.J., in 1909, of the reduction of bacteria by the introduction of minute quantities of "available chlorine" with water more or less polluted, and the acceptance of the process by the courts as a proper method to be employed in connection with a municipal water supply, the question of the efficient introduction of hypochlorite of lime solution and the mechanical appliances suitable for the purpose engaged the attention of the fire and water commissioners of this city. They ordered the city chemist, Dr. W. M. Cross, to make a trip of inspection of several cities known to have the hypochlorite sterilization system in satisfactory operation.

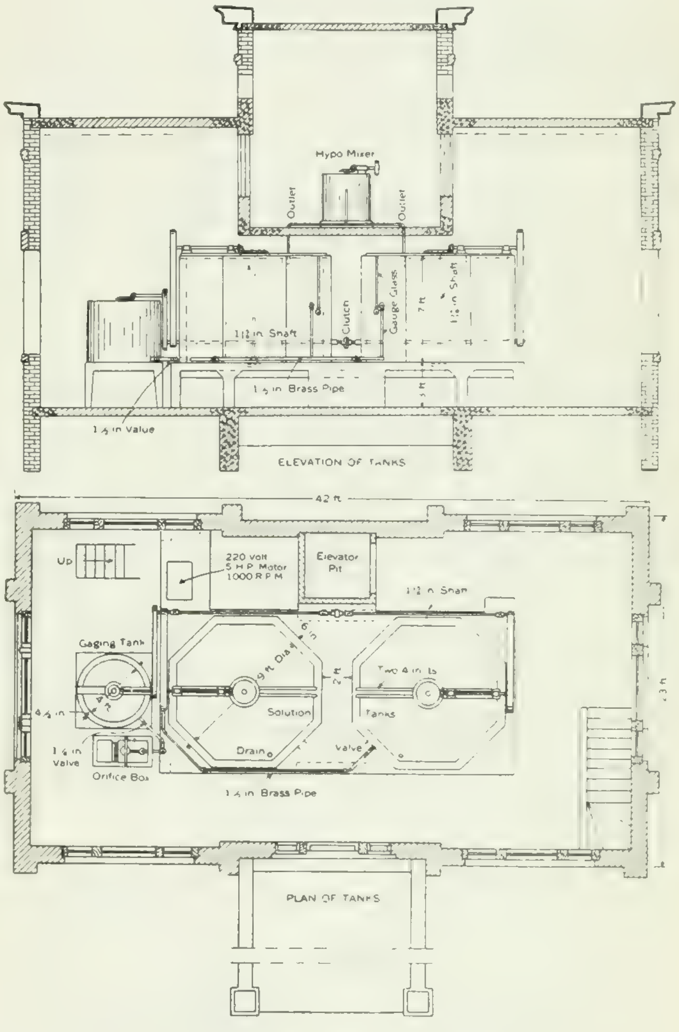
Dr. Cross found the method of installation of the system easy, cheap and satisfactory. During the year 1911 an experimental installation of the hypochlorite process for the approximate sterilization of the entire municipal water supply of Kansas City was so successful that the Kansas City fire and water commissioners undertook the construction of a permanent building and apparatus for the application of this purification process to the entire water supply.

A separate building was constructed to make possible the satisfactory storage, handling and making of the solution of hypochlorite ready for mixing with the sedimented water. The building itself was designed by W. C. Root, an architect, and the apparatus for use in connection with the sterilization process was installed under the direction and supervision of Burton Lowther, engineer in charge.

The apparatus for the handling of the hypochlorite and the supports for it are of reinforced concrete. It is to be observed that no other material is so well suited for use in connection with this sterilizing agent as good concrete, for the reason that all other materials that are capable of oxidation are promptly attacked by the hypochlorite solution and become rapidly deteriorated. The prime consideration with regard to this class of installation is to employ methods of construction and to use material that is so permanent in character as to obviate the necessity of repairs which would force the discontinuance of the application of the sterilizing agent, even for an hour.

The basement of the building is used for storage of the reagent that is kept in reserve. The main floor is used to house the dilution tanks and the feeding devices, while on the floor above is placed the tank in which the hypochlorite is reduced to paste of a creamy consistency before being delivered to the dilution tanks beneath. This pasting tank, three feet in diameter and four feet high, is provided with a stirring device carrying two rather heavy rollers disposed horizontally at its lower end.

The rollers clear the bottom of the concrete tank only by a fraction of an inch, thus insuring the mashing and disintegration of all of the small lumps that are invariably present in commercial calcium hypochlorite. Owing to the fact that the action of the reagent on bronze is to form on the surface of it a fairly insoluble and protective coating of metallic carbonate and oxychloride, that metal appears to be the most available for use on all bearings and stirring or disintegrating devices that come in contact with the solution. Leading from the concrete pasting tank are pipes so arranged that the contents of the tank may be discharged into either of the large dilution tanks on the floor beneath. The outlet of the pasting tank is placed at a considerable distance from its bottom, so as to avoid the possibility of drawing off with the paste any fragments of considerable size. The pipes carrying the paste are so arranged as to be readily cleaned in a few minutes in the event that they become clogged. Ultimately, they are sure to become clogged if they are not occasionally cleared, because of the formation in them of carbonate from carbon dioxide absorbed from the air.



Hypochlorite Sterilization Plant at Kansas City, Mo.

---

* Paper read before American Waterworks Association.

The dilution tanks are hexagonal in form, nine feet in maximum diameter and seven feet high. Their walls are six inches thick. Although the difficulty experienced in properly disposing the reinforcing iron in the construction of a hexagonal tank is much greater than is the case in the building of a round one, the hexagonal tank is to be preferred on account of the fact that in a round tank a rotary stirrer does not produce nearly such thorough agitation and mixing of the solution of hypochlorite as the same stirrer can do in the hexagonal tank. The paste is mixed with water in the dilution tanks until a uniform solution of a strength of 2 per cent. occurs. The use of two tanks makes it possible to accurately adjust the strength of the solution in one solution tank while the contents of the other are being utilized. The dilution tanks are placed on supports high enough to permit the use of a gravity feed to the orifice box, which is placed on the floor of the room housing the big tanks.

Bronze pipes, 1½ inches in size, so arranged as to be readily cleaned in the event of stoppage, connect the dilution tanks with a gaging tank four feet in diameter. This gaging tank contains a float, scale and pointer so arranged that the man in charge can accurately check the speed of outflow of solution from his orifice box into the big water main carrying the entire city water supply from the settling basins to the pumps. The solution passes through the gaging tank to the orifice box. Each division on the gage represents one gallon of the hypochlorite solution.

The orifice box is oblong in shape and carries a float of about 250 cubic inches displacement. The float operates a valve which, by either opening slightly or closing, maintains the hypochlorite solution in the orifice box to a constant level. One end of the orifice box is of plate glass to enable the operator to see at a glance that the solution is filling the box to the proper height. Attached to the plate glass and covering a hole in it is a hard rubber disc having near its periphery several slits, the adjustment of which fixes the size of stream of the 2 per cent. hypochlorite solution that will be the proper amount to treat the quantity of water passing through the main. All movements of the hypochlorite solution after its preparation are by gravity. Ample opportunity for the hypochlorite, after its addition to the water, to react with the putrescible organic matter and germs is afforded during the time in which the water passes through the centrifugal pump, the flow line and a small storage basin at Turkey Creek, where it is pumped to the domestic water mains.

All stirring devices are run by an electric motor belted to a line shaft carrying pulleys so placed as to make possible the turning of any one of the stirrers, whether or not [illegible].

[illegible] municipal water supplies is substantially the same as that in [illegible]

[illegible]

cents per million gallons, so that it probably will not exceed that amount, including interest and depreciation, as the pumpage during the hot and cold months averages over forty million gallons.

In view of the fact that a great many cases of typhoid fever are imported and that there are still open and being constantly used numerous springs, wells and cisterns, known to be contaminated with sewage, the result has been all that could have been anticipated. During the year 1910 no specific attempt was made to destroy pathogenic germs in the municipal water supply. During the year 1911 the hypochlorite process was used throughout the year.

The following tabulation, showing the number of deaths from typhoid fever, month by month, during those years, is illuminating:

Month.	**Deaths.**	
	1910.	1911.
January	17	6
February	21	6
March	10	4
April	8	3
May	3	4
June	7	1
July	9	5
August	8	6
September	6	3
October	6	8
November	4	6
December	8	9
Totals	107	61

Now, with this great source of danger from infection by the municipal water supply removed, it is possible for the health commissioner to so enforce the abandonment of questionable sources of water supply and regulate sanitary conditions as to make the occurrence of typhoid fever and most intestinal diseases an uncommon thing in Kansas City.

The following are some germ counts on the city water supply, showing the improvement of the water by the hypochlorite process:

Germs in one Cubic Centimeter of Water.

Date.	Quindaro, Missouri River Before Treatment.	Clear Basin Before Treatment.	City Hall Hydrant After Treatment.	B. Coli After Treatment.
March 20	10,000	1,200	75	0
March 21	8,000	1,800	70	0
March 22	4,000	800	100	0
March 24	10,000	500	55	0
March 25	8,000	600	90	0
March 27	8,000	400	25	0
March 28	5,000	260	20	0

The accompanying cut will give a fairly good idea of the disposition of the various parts of the purification installation.

A NEW USE FOR THE SULPHUR LIQUOR DISCHARGE OF GAS WORKS.

A French investigator, A. Demolon, found that when the soil was given a quantity of flowers of sulphur, the growth of roots and leaves was invariably hastened and the plants took on a deeper green. The investigation was suggested by the common use in northern France of gas works waste as manure. Analyses showed 30 per cent. of sulphur in this waste, and the growth stimulation was traced to this ingredient.

THE USE OF CHARTS IN THE PREPARATION OF ESTIMATES.

The following article by Mr. Edward G. Fiegehen, published recently in London "Engineering," contains material of so valuable a nature that we have reproduced it in full.

In the preparation of estimates of all kinds, time enters as a most important factor. It may become necessary, for instance, in order to take advantage of an unexpected opportunity of quoting, to compile a specification and estimate at the shortest possible notice, whilst, on the other hand, as in the case of tenders to public bodies, a definite date, generally two or three weeks ahead, is announced up to which tenders will be received; and since the tenders sent in remain unopened until after that date, no benefit is to be gained by posting them in advance. The bulk of inquirers, however, are content to receive tenders at the "early convenience" of the manufacturers concerned, and although the majority of firms will submit their proposals in the course of a few days, there are notable exceptions where the estimating departments appear to be constantly in arrears.

Without discussing, on the one hand, the advantages to be gained by being first in the field with a complete and attractive proposal, or, on the other hand, the risk thereby incurred of having one's price divulged for the guidance of a competitor, there can be no question that any method that will lighten the labor involved in preparing a tender by reducing the time absorbed by the merely mechanical portion of the work will thereby enable the estimator to give greater attention to the special features of each case, and will tend to prevent his work getting behindhand during those periods when inquiries are exceptionally numerous; furthermore, it will enable him in many cases to submit alternative proposals, for which, in the ordinary way, no time could be spared. We shall confine our remarks in what follows more especially to the preparation of estimates for electric-crane work; but it will be obvious that the methods advocated can be applied with equal facility to other branches of manufacture.

An advantage of such time-saving devices that appeals with special force to the estimator for crane-work is the ability thus secured to determine quickly the type, leading dimensions, approximate weight, electrical equipment, etc., appropriate to the crane he intends to offer, thus enabling him to get an estimate-drawing put in hand in ample time to allow the draughtsman to produce a satisfactory design.

By way of illustration, the charts described below will refer chiefly to the specific case of electric overhead traveling cranes. The number of types of cranes regularly manufactured is now very great, but perhaps no other is so popular, or exhibits more variation in its essential features, than that selected; for whilst it will frequently be possible to quote for a steam or electric jib-crane or winch directly from a standard price-list, with overhead cranes this is rarely the case, and each inquiry must be considered upon its merits to enable the most suitable offer to be put forward. In tackling such problems, it is found to be a good rule to deal with the known factors first, afterwards deciding the various points upon which the exercise of judgment is permitted.

In the case of established buildings the space available for the crane, and the nature of the current supply, are usually definitely stated by the customer; but since inquiries are frequently ambiguous even upon such essential points, it should be the rule to state definitely in the specification the basis upon which the estimate has been prepared, and to show clearly upon the drawing the space required for the satisfactory operation of the crane, indicating also any projections that would be likely to foul existing fixtures in the building, and also the position suggested for the main trolley-wires.

Such information is invariably of far greater service to the engineer than fullness of constructional details, which are far better indicated by photographs of similar jobs.

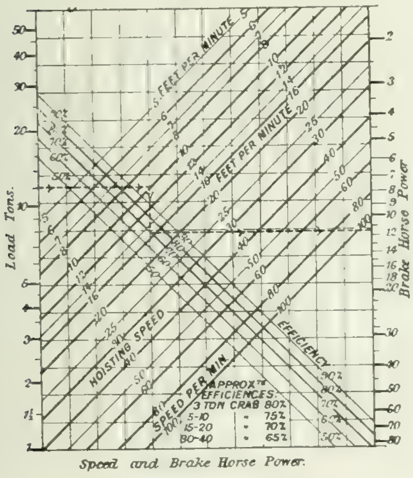


Fig. 1.

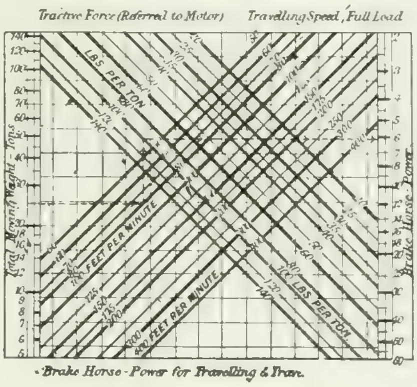

Fig. 2.

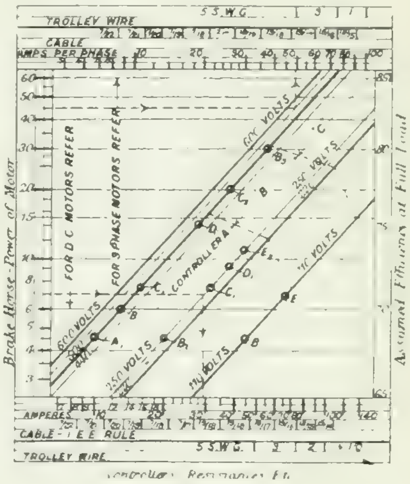

Fig. 3.

The speeds of the various motions under full load are sometimes specified by the customer, although in many instances these details are left to the judgment of the maker. In any case, however, it is generally open to the latter to submit speeds in accordance with his standard practice as an alternative, if by so doing he can quote a reduced price, or, perhaps more acceptable, earlier delivery, due to the use of stock patterns and parts. The first chart, Fig. 1, which is based upon the formula:—

$$\text{B.H.P.} = \frac{0.068 \times \text{load (tons)} \times \text{speed (f.p.m.)}}{\text{Efficiency}}$$

shows the connection between hoisting speed and brake horse-power for various loads, taking into account, of course, the mechanical efficiency of the crab-gearing under full load, which will vary both with the size of the crane and the type of gearing employed. The estimator will usually have access to test records for his guidance upon this point, but the approximate values given may be taken as typical of machine-cut spur-geared crabs under favorable conditions.

The next chart (Fig. 2) will, in a similar way, facilitate the calculation of the brake horse-power required for the traversing and traveling motions, and is based upon the formula:—

$$\text{B.H.P.} = \text{total moving load (tons)} \times \frac{\text{tractive effort} \times \text{speed (f.p.m.)}}{33{,}000}.$$

In working out test records of overhead cranes it is usual to express the "tractive effort" in pounds per ton as exerted at the motor thus:

$$\text{Tractive effort (pounds per ton)} = \frac{\text{Motor B.H.P.} \times 33{,}000}{\text{Traveling speed} \times \text{tons moved}}.$$

It will be noticed that the figure thus obtained contains an allowance for the transmission losses between the motor and the track-wheel treads, and is thus in the most convenient form for use, provided that the above qualification is not lost sight of.

To secure simplicity and, where possible, interchangeability of parts it is the commendable practice of many firms to confine themselves to a few standard powers and speeds of motors for use upon their cranes, and thus, in quoting, they will put forward the nearest standard motor that will be suitable for each motion.

This involves sometimes, it is true, offering a 10-brake horse-power motor where only 8½ brake horse-power to 9 brake horse-power is actually indicated; but the difference in cost is inappreciable, and in such cases the offer of increased speed that will thus be obtainable may sometimes be made available as a selling point.

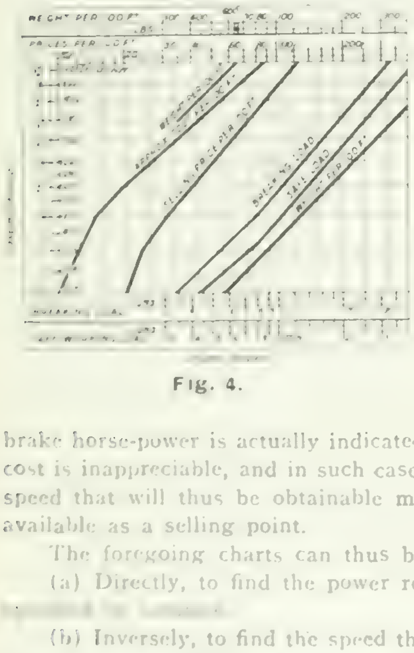

Fig. 4.

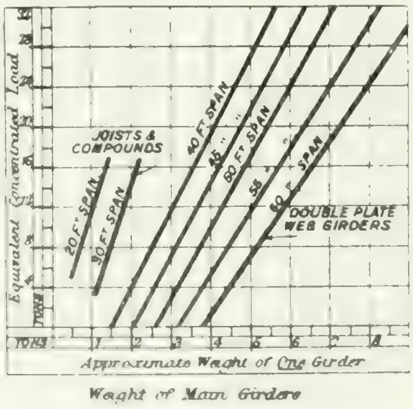

Fig. 5.

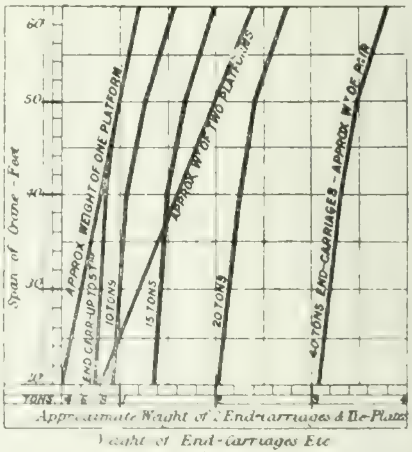

Fig. 6.

The foregoing charts can thus be used in two ways:—

(a) Directly, to find the power required from the speed [illegible]

(b) Inversely, to find the speed that the nearest standard motor, when applied to the motion, will give.

Having fixed the size of the motors to be employed, the next chart (Fig. 3) will enable us to determine approximately the current consumption of each at full load, and can be used both for continuous current and three-phase induction-motors, the current in the latter case being, of course, the [illegible] throughout.

From the same chart, and upon the basis of current and voltage, the most suitable sizes of controllers, resistances, cables, and trolley-wire can be ascertained for normal cases. [illegible] to agree with [illegible] In Fig. 3 the lines and circles, indicating respectively the capacity of controllers and resistances, refer only to a certain make by way of illustration, and will have to be modified to suit the limits of the controlling apparatus actually put forward.

Turning now to the mechanical features of the crane, we have the chart (Fig. 4) giving the leading particulars of lifting-ropes.

Here, again, the prices shown refer only to a particular case, and the user would modify them to suit his requirements. The grade of rope covered is of 100 to 110-ton wire, up to 1¾-in. circumference, and of 90 to 100-ton wire for the larger sizes, and a variable factor of safety, from 8 in the smallest size to 6 for the 3-in. rope, has been introduced.

In the preparation of such estimates as we are now considering the greatest variant, perhaps, at least in cranes of medium and long spans, is the weight and type of the main girders.

With the exception, perhaps, of deflection, it is rare for any stipulation to be made in the inquiry concerning these, and consequently it is not surprising that the offers submitted in any particular case differ materially in many respects, having regard to the difference of opinion that is bound to exist as to the most suitable type, depth, and working stress.

This discrepancy is generally most marked at those spans and loads where the carrying capacity and stiffness of joists and compounds reaches a limit, and it becomes, therefore, a matter of judgment or policy whether riveted girders should be put forward.

The calculation of the approximate weight of a girder for a given duty involves of necessity a provisional estimate of this weight in order that the bending tendency of this can be duly allowed for. Upon short spans the accuracy of this preliminary estimate is of small importance, but upon long spans, especially when associated with the smaller lifting capacities, it becomes the paramount item of the loading, and it will, therefore, be necessary to exercise the greatest care in its determination.

The chart, Fig. 5, is intended to facilitate the estimation of the weight of main girders of normal construction.

To ascertain the "equivalent concentrated load" upon each girder, we must add to half the weight of the crab and of the maximum load half the estimated weight of the girder itself and its platform, if any.

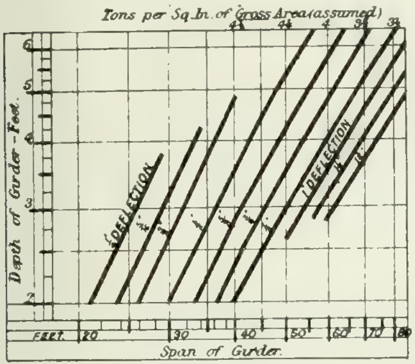
By reference to the chart we can now find the approximate weight of the girder required; but should our first attempt indicate that our provisional estimate of this weight was incorrect, the "equivalent concentrated load" assumed must be modified, and a second reading taken.

It will be noticed that the curves upon this chart, from 40-ft. span upwards, refer to double-plate web girders only.

Lattice-braced girders may be expected to show a slight saving in weight at this span, increasing to, say, 25 per cent. saving upon the longer spans and heavier loads. Since, however, it is usual to give the customer the option of plate-web or lattice-girders at the same price, the basis of plate-web weights for estimating is usually the safest.

The estimation of the structural weight of end-carriages cannot be systematized to any extent owing to the variation in their design due to different modes of attachment to the main girders, governed mainly by the amount of head-room available for the crane. The chart, Fig. 6, may, however, be taken as a rough guide in the absence of more definite data or of detailed calculation, the weights given referring to a pair of end-carriages with their appropriate tie-plates for attachment to the main girders in each case.

The chart also indicates the approximate weight of the usual timber platform with its hand-railing and brackets.



Deflection of Girders

Fig. 7.

In the case of girders the estimator is frequently required either to work to a given maximum deflection, or to specify what maximum deflection he is prepared to guarantee under test.

To the case of a built-up beam of varying depth, such as the typical crane-girder, the ordinary theoretical formula cannot be conveniently applied. The chart, Fig. 7, has therefore been based upon an empirical rule, recommended by Thorpe, as follows:—

$$\text{Deflection (inches)} = \frac{(\text{span in feet})^2 \times \text{stress on gross flange area}}{4000 \times \text{depth in feet}}$$

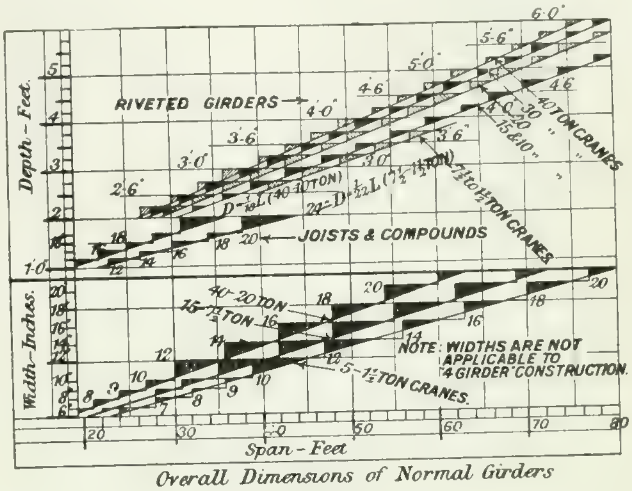
This represents the results of experience with riveted girders, and accords fairly well with practice. It should be noted particularly that the stress in the present instance is the mean stress taken over the gross area of the flange, no deduction being made for rivet-holes.

In preparing the chart, a stress of 4½ tons per sq. in. of gross flange area has been assumed up to 40 ft. span. Beyond this, some provision will be required upon the flange area of the girders to supply the necessary lateral strength, and to allow for this upon the chart the direct stress due to vertical loading only, and taken over the gross area, has been assumed to diminish uniformly from this value to 3½ tons per sq. in. only at 80 ft. span. By the use of this chart it can be readily seen whether the girder proposed will be stiff enough to comply with the specification, and, if not, to what extent the stress or depth must be modified to secure the desired result.

It is often desirable to specify the depth and width of the girders proposed, and although the designer's judgment will not mislead him greatly in this matter, a chart such as that shown in Fig. 8 tends to uniformity in this respect and prevents overlapping. It will be noticed that the depths and widths advance by steps at definite spans to correspond to market sizes or level figures, and that the proportion of both width to span and depth to span varies slightly according to the capacity of the crane.

It is fairly safe to assert that the bête noir of the average estimator is the preparation of the detailed shipping specification that must accompany all quotations for export trade. In the compilation of such sheets guessing plays an altogether too conspicuous part.

If, on the one hand, the result errs upon the side of too great weight and bulk, the tender may be ruled out at once on that account alone; whilst should a "light" specification assist in securing the order, the firm run the risk of losing the confidence of its client, who will not relish having to pay any unexpected additional freight.

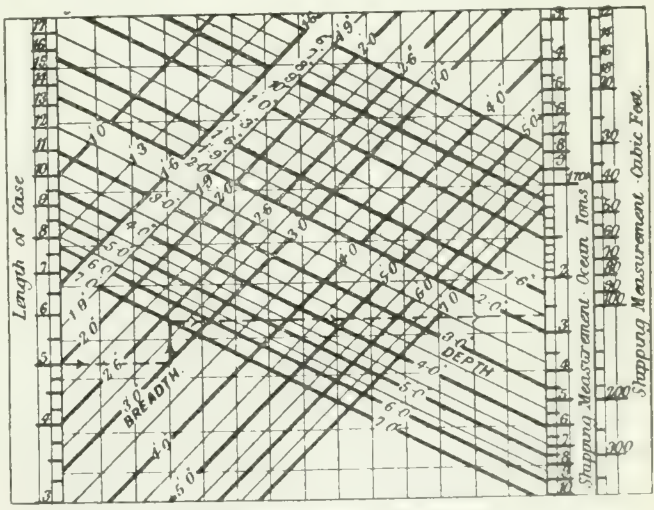


Overall Dimensions of Normal Girders

Fig. 8.

Any means, therefore, that will reduce the uncertainty and labor of the process is a step in the right direction. For standard cranes a form of specification should be decided upon and adhered to, and it will generally be found that many of the items remain unaffected by changes in span, etc.

For reducing the shipping measurements of the various items to cubic feet or ocean tons, as may be preferred, Fig. 9 will be found of great service, the accuracy obtainable being quite sufficient for all ordinary purposes.



Shipping Measurement of Packages

Fig. 9.

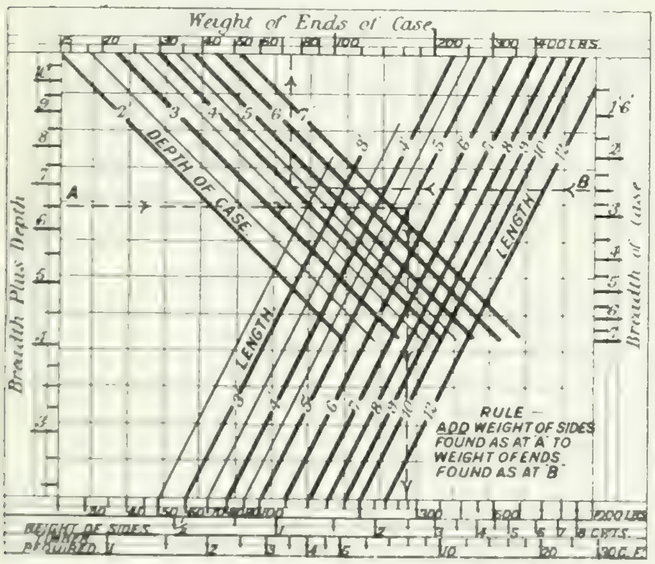
Clients frequently ask for both gross and net weights of packages to be stated. Owing to the time involved in looking up previous packing-lists of similar work, the weights of the various packing-cases are frequently guessed at, a process that can hardly be considered satisfactory. Our last chart, Fig. 10, is intended to show the approximate weight of ordinary unlined cases of 1¼ in. deal, and by its use consistent results of reasonable accuracy can be obtained with great rapidity.

By the use of the bottom scale in conjunction with those immediately above it the number of cubic feet of timber used in the construction of the case can be estimated.

In the foregoing we have endeavored to indicate briefly some methods of economizing time and labor in the preparation of estimates. Our examples have necessarily been confined to one type of crane only, but other applications will readily occur to the reader.

It is desirable that such charts should be boldly and clearly constructed to facilitate ready reference, to prevent mistakes, and, above all, to avoid that appearance of great accuracy that fine lines and close divisions always tend to produce.

It is quite possible to obtain great accuracy by the use of such charts, but for our present purpose such accuracy is not only unnecessary, but inconsistent with the data available. Charts for estimating purposes should be drawn to a liberal scale, upon tough paper or tracing-linen, and arranged in a binder with a suitable thumb index.



Approximate Weight of Packing Cases 1¼ In. Deal

Fig. 10.

For the greatest utility their scope should not be too ambitious, and they should be so clear that in the majority of [illegible] the results can be read without the aid of a pointer to trace them from one set of lines to the next.

By the use of logarithmically-divided base-lines almost any ordinary formula can be represented by parallel straight lines, [illegible] eliminating the labor and likelihood of error introduced when [illegible] further, the parallel lines facilitate the reading of the chart.

The foregoing remarks and illustrations touch, of course, [illegible]

[illegible]

PRODUCTION IN CANADA OF STRUCTURAL MATERIALS AND CLAY PRODUCTS.

The value of the production of mineral water in 1910 for which returns were received by the Department of Mines, Ottawa, was $199,563, as compared with a value of $175,173 in 1909. The imports of mineral and ærated waters in 1910 were valued at $202,306, as against a value of $184,071 in 1909.

The value of the production of natural gas in 1910 was $1,346,471, as compared with a value of $1,207,029 in 1909 and $1,012,660 in 1908. Shipments of peat for fuel purposes in 1910 were 841 tons valued at $2,604, as compared with 60 tons valued at $240 in 1909.

The production of crude petroleum shows another large falling off in 1910, the production being only 315,895 barrels or 11,056,337 gallons valued at $388,550; as compared with 420,755 barrels or 14,726,433 gallons valued at $559,604 in 1909. Exports of refined oil in 1910 were 2,818 gallons valued at $462, and 7,768 gallons valued at $934 in 1909.

While the production has been decreasing the imports have been increasing; the total output of the petroleum oils, crude and refined, in 1910 was 84,629,334 gallons valued at $4,826,763, in addition to 1,362,235 pounds of wax and candles valued at $80,106. The oil imports included: crude oil, 53,604,053 gallons valued at $1,639,358; refined and illuminating oils, 7,656,727 gallons valued at $502,364; gasoline, 16,679,691 gallons valued at $1,693,296; lubricating oils, 4,081,257 gallons valued at $718,381, and other petroleum products, 2,607,606 gallons valued at $273,364.

The total imports in 1909 were 58,317,101 gallons, valued at $3,353,311, in addition to 467,731 pounds of wax and candles valued at $40,689. The oil imports in 1909 included: crude oil, 35,884,103 gallons, valued at $1,186,400; refined and illuminating oils, 9,632,595 gallons, valued at $705,971; gasoline, 7,452,762 gallons, valued at $706,994; lubricating oils, 3,909,117 gallons, valued at $558,632, and other petroleum products 2,038,524 gallons valued at $195,314.

Phosphate, Pyrites and Quartz.

Shipments of phosphate or apatite in 1910 were 1,478 tons valued at $12,578, as compared with 998 tons valued at $8,054 in 1909. There were no exports reported in 1910, as against 895 tons valued at $15,735 in 1909. The imports of phosphate rock (fertilizer) in 1910 were valued at $72,950; phosphorus, 6,752 pounds valued at $2,065, and manufactured fertilizers valued at $388,467.

The production of pyrites in 1910 was 53,870 tons valued at $187,064, as compared with 64,644 tons valued at $222,812 in 1909. The exports of pyrites in 1910 were 30,434 tons valued at $110,071, as against exports of 35,798 tons valued at $156,644 in 1909. The imports of brimstone or sulphur in 1910 were 22,835 tons valued at $474,619, as against 22,887 tons valued at $458,061 in 1909.

The quartz production in 1910 was reported as 88,205 tons valued at $91,051, compared with a production in 1909 of 56,924 tons valued at $71,285. There were imported during 1910, 628 tons of silex or crystalized quartz, valued at $11,996, and, in 1909, 559 tons valued at $8,733.

Production of Salt, Talc and Tripolite.

The total sales of salt in 1910 were 84,092 tons valued at $409,624 (exclusive of packages). The value of the packages used was $173,446. In 1909 the sales were 84,037 tons valued at $415,219, and value of packages used, $175,612.

Exports of salt in 1910 were [illegible] pounds, valued at [illegible], and, in 1909, [illegible] pounds valued at $2,488. The total imports of salt in 1910 were valued at $462,061, and included: 20,174 tons valued at $97,326, subject to duty; and [illegible] tons valued at [illegible], duty free. The 1909 imports were valued at $431,221 and comprised: 112,554 tons of salt subject to duty, valued at $352,165; and 16,857 tons duty free, valued at $79,056.

The imports of soda products in 1910 included: soda ash or barilla 35,596,006 pounds, valued at $306,167; soda bichromate 878,777 pounds, valued at $32,842; caustic soda in packages of 25 pounds or more 13,848,170 pounds, valued at $260,938; sal soda 9,715,272 pounds, valued at $72,845, and sulphate of soda 17,728,543 pounds, valued at $95,054.

The production of talc increased from 4,350 tons, valued at $10,300, in 1909, to 7,112 tons, valued at $22,308, in 1910.

There was a production of 22 tons of tripolite, valued at $134, reported for 1910 and no production in 1909.

Structural Materials and Clay Products.

The total sales of cement in 1910 were 4,753,975 barrels, valued at $6,412,215, as against 4,067,709 barrels, valued at $5,345,802, sold in 1909, showing an increase of 686,266 barrels. The exports of cement in 1910 were valued at $12,914, compared with exports valued at $113,362 in 1909.

The imports of cement in 1910 included: manufactures of cement, valued at $7,718; hydraulic cement, 365 hundredweight, valued at $349; and Portland cement, 1,222,586 hundredweight (349,310 barrels) valued at $468,046. The imports in 1909 were: manufactures of cement, valued at $6,374; hydraulic cement, 682 hundredweight, valued at $614; and Portland cement, 497,678 hundredweight (142,194 barrels) valued at $166,669.

The consumption of Portland cement in Canada in 1910 was approximately 5,103,285 barrels, as compared with 4,209,903 barrels in 1909.

The total value of the production of clay products in Canada in 1910 was $7,629,956, as compared with a total value of $6,450,840 in 1909. Brick and tile products alone were valued in 1910 at $6,377,728, as against $5,327,815 in 1909. The value of sewerpipe production in 1910 was $774,110, as compared with $645,722 in 1909. The only clay products exported in 1910 were: 390,000 building brick, valued at $2,762, and the manufactures of clay valued at $9,061; against 365,000, valued at $2,255, in 1909, and manufactures valued at $979. The total imports of clay products in 1910 were valued at $4,331,397, and included: brick and tile valued at $1,755,773; earthenware and chinaware, $2,283,116, and clays valued at $292,508. The total imports in 1909 were valued at $3,247,539, comprising: brick and tile, $1,249,450; earthenware and chinaware, $1,781,759, and clays, $216,330.

Lime, Sand Lime Brick and Slate.

The total production of lime in 1910 was 5,848,146 bushels, valued at $1,137,079, as compared with 5,592,924 bushels, valued at $1,132,756, in 1909. The exports of lime in 1910 were valued at $44,762, as against exports valued at $48,821 in 1909. The imports of lime in 1910 were 212,502 barrels, valued at $138,847, and in 1909, 168,357 barrels, valued at $118,239.

The total sales of sand-lime brick in 1910 by 13 firms reporting were 44,593,541, valued at $371,857, an average value of $8.34 per thousand. The sales in 1909 by 9 firms reporting were 27,052,864 brick valued at $201,650, an average of $7.45 per thousand.

The production of slate in 1910 was 3,959 squares valued at $18,492, and 4,000 squares, valued at $19,000, in 1909.

The imports of slate in 1910 were valued at $142,285, and included: roofing slate, valued at $67,063; school writing slate, $31,397; slate pencils, $6,948, and manufactures of slate, $36,877.

The imports in 1909 were valued at $135,221, comprising: roofing slate, $71,914; school writing slate, $34,085; slate pencils, $6,154, and manufactures of slate, $23,068.

Stone Production of all Kinds.

The total value of the production of stone of all kinds, in 1910, was $3,650,019, as compared with a value of $3,127,135 in 1909. The value of stone exports in 1910 was $27,471, as against $59,370 in 1909; and the total value of stone imported in 1910 was $845,123, as against imports valued at $683,801 in 1909.

The production in 1910 included: granite valued at $739,516; limestone, $2,249,576; marble, $158,779, and sandstone, $502,148. In 1909 the production of granite was valued at $454,824; limestone, $2,139,691; marble, $158,441, and sandstone, $374,179.

Classifying the output according to the purposes for which the stone was used, the production in 1910 comprised: building stone, valued at $1,504,001; ornamental and monumental stone, $147,421; paving and curbstone, $239,668; rubble, $352,000; crushed stone, $975,379; and furnace flux, $431,550; while in 1909 the production included: building stone, valued at $1,170,550; ornamental and monumental stone, $306,338; paving and curbstone, $279,227; rubble, $303,120; crushed stone, $664,287, and furnace flux, $403,613.

◆

NEW RAILWAY FOR NORTH-WESTERN CANADA.

Forty survey parties, consisting of 800 men with teams and pack horses, will be sent into the field at once from Edmonton to make preliminary surveys for the Northern Territorial Railway company's line from Edmonton to tidewater at Fort Churchill on Hudson's Bay. This is to be part of a system of 1,450 miles, from the Hudson's Bay country to Port Essington on the Pacific Coast, connecting Edmonton with Lac La Biche, Fort McMurray and Lake Athabasca.

H. G. H. Neville, C.E., chief engineer for the company, which is financed by a British syndicate and capitalized at $40,000,000, has covered every portion of the proposed route and is fully satisfied upon the engineering problems presented in the construction of the system.

The route is from a point at or near Fort Churchill or Fort Nelson on the Hudson's Bay, thence westerly to a point at or near the south shore of Lake Athabasca, in the province of Alberta, thence westerly and north of the Peace River block, thence southwesterly by the nearest possible route through the Rocky Mountains to a point on the Pacific Coast at or near Port Essington at or near the Portland Canal and from a point on the said railway near the crossing of the Athabasca River, in the province of Alberta, southerly to a point at or near Fort McMurray, thence southerly to a point at or near Lac La Biche, thence by the most feasible route to the city of Edmonton.

Plans are under way to begin grading work early next season, when the laying of rails will also be carried on, and in two years, according to present calculations, the line is to be in operation from Edmonton to the shore of Lake Athabasca, opening to commercial development the vast mineral and timber wealth of Alberta's farthest north. The company will then proceed with the construction of the line in the province of Saskatchewan. The Edmonton cut-off will be built later. The line from Lake Athabasca westerly will tap the rich agricultural resources of the newest north, continuing thence to the Pacific Coast.

The Northern Territorial Railway Company will operate a line of steamships from its Hudson's Bay terminal to a British port. Engineers in the employ of the corporation have made a study of the construction of ice-breakers in the Baltic and are now working on designs of vessels capable of meeting the abnormal conditions which prevail in Hudson's Bay.

RAILROAD EARNINGS.

The following are the railroad earnings for the week ended July 7th:—

	1911.	1912.	Increase or decrease.
C. P. R.	$2,096,000	$2,571,000	+ $475,000
G. T. R.	943,095	1,012,051	+ 68,956
C. N. R.	346,500	391,900	+ 45,400
T. & N. O. R.	28,547	28,272	— 275
Halifax Electric	5,696	5,808	+ 112

The following are the railroad earnings for the week ended July 14:—

	1911.	1912.	Increase or decrease.
C. P. R.	$2,170,000	$2,701,000	+ $531,000
G. T. R.	994,800	1,037,863	+ 430,063
C. N. R.	364,700	436,700	+ 72,000
T. & N. O. R.	28,241	26,699	— 1,542
Halifax Electric	5,270	5,686	+ 416

The Grand Trunk Railway has issued its statement of earnings and expenses for May and for the five months of the fiscal year. Taken altogether, the results are favorable, notwithstanding the fact that the revenue for this has been largely cut into owing to extraordinary outlays for extensions and improvements all over the system.

The roads in the Grand Trunk system report for May and five months as follows:—

Grand Trunk of Canada.

	1912.	1911.	Increase or decrease.
May gross	£691,700	£628,800	+ £62,900
Net	207,000	206,500	+ 500
Five months' gross	691,700	2,831,000	+ 221,500
Net	696,400	724,800	— 28,400

Canada Atlantic.

	1912.	1911.	
May gross	£ 41,500	£ 38,100	+ £ 3,400
Net	def 450	4,700	+ 3,250
Five months' gross	172,750	163,600	+ 9,150
Net	3,900	18,900	— 15,000

Grand Trunk Western

	1912.	1911.	
May gross	£114,500	£108,550	+ £ 5,950
Net	23,800	def. 150	+ 23,950
Five months' gross	549,600	552,350	— 2,750
Net	[illegible]	48,050	+ 12,050

Detroit, Grand Haven and Milwaukee.

	1912.	1911.	
May gross	[illegible]	£ 34,500	+ £ 2,000
Net	[illegible]	def. 850	+ 1,650
Five months' gross	[illegible]	177,950	+ 2,050
Net	[illegible]	[illegible]	+ 5,700

While the annual statement of the Canadian Northern Railway is not yet prepared for publication, it will be shown that the gross earnings for the year ended June 7, will be approximately $21,000,000 compared with $16,360,000 for the [illegible]

The general increase in business through the West is reflected in the fact that this increase of 29 per cent. in earnings [illegible] per cent. over last [illegible] At present the [illegible] miles last year

Particularly in the movement of grain have traffic con- [illegible] Canadian Northern [illegible] per cent.

Two hundred and sixty miles of track have now been completed west of Cochrane, Ont., on the National Transcontinental Railway, according to latest reports, and an average of a mile a day is being laid. Rails have been laid from Superior Junction to Winnipeg, leaving a distance of 184 miles yet to be covered with steel between the former point and the present rail-head west of Cochrane. Those in charge of the work expect to have the entire line between Cochrane and Winnipeg finished by the end of September.

◆

EXPERT WOODSMAN REPORTS ON FOREST CONDITIONS.

The timber of the Hudson Bay region (the southern part of the old district of Keewatin) is a topic that has lately become of considerable interest. Interesting observations with regard to it are found in the 1911 report of the Director of Forestry, published as part of the annual report of the Department of the Interior for 1911. These are in continuation of the report on the timber along the proposed line of the Hudson Bay Railway, published as Bulletin No. 17 of the Forestry Branch.

Mr. J. T. Blackford, an experienced woodsman, acquainted with the conditions in the north, reports on the conditions of the forest around Oxford House, his explorations covering some 5,400 square miles of country. Of this only about 1,600 square miles bears merchantable timber; on the remaining 3,800 miles the timber has been burned. There is abundant evidence that the whole country was originally forested with spruce, tamarack, jack pine, balsam fir, birch and poplar, and on islands which have by their position been protected from fire are dense stands of trees two to three feet in diameter.

The areas, after the first burning, have usually been covered with dense growth of trees, but the debris left after the first almost invites a second fire. In many places fire has swept the country many times, impoverishing the soil, destroying all seed-trees, and with them all hope of a second forest. "During the summer," the report states, "Mr. Blackford found no commercial timber of any quantity, but he states that, except for fire, the country would be covered with timber two or three feet in diameter."

◆

THE HOLDING POWER OF SPIKES.

Tests of the holding power of spikes in railroad ties and of the resistance of the wood fibre to indentation by tie-plates have been made during the past year at the Armour Institute by the Board of Supervising Engineers of the Chicago Traction lines. The results are presented in a recent report. The principal object of the spike tests was to determine the comparative holding power of the standard track spike and the screw spike. It was found that though the holding power of the screw spike is approximately three times that of the square spike, the relative holding powers in different timbers is such as to make the screw spike in treated pine fully equivalent to the standard spike in white oak. The tests of indentation of the tie plates showed that the ratio of resistance of a flat-bottom plate to that of a corrugated-bottom plate is much greater than the ratio of the bearing areas. The indentation of the corrugated plate is considerably greater for the same load per unit of surface contact. The tests also showed that chloride-of-zinc treatment of loblolly and short leaf yellow pine increases the fibre strength to an extent making them compare favorably with the long leaf yellow pine in resisting the indentation of tie plates.

PERSONAL.

MR. M. K. ALLEN has resigned from the position of city engineer of Regina, Sask.

ALD. CHISHOLM has resigned his position as chairman of the Board of Works, Toronto, to become property commissioner of the same city.

MR. G. A. DUDLEY, of Windsor, N.S., has been appointed to a position on the engineering staff of the St. John Valley Railroad.

MR. A. S. RUNCIMAN, who was with the Canadian Westinghouse Company, at Calgary, is now assistant superintendent of the electric light department of Prince Albert, Sask.

MR. FRANK E. BELFRY, of the firm of Thomson and Belfry, has been selected for the position of architect assistant superintendent of buildings under the Board of Education for the city of Toronto.

MR. R. S. LEA, Mem. Can. Soc. C.E., Mem. Am. Soc. C.E., M.I.C.E., has recently removed his office from 405 Dorchester Street West, to Room 820 New Birks Building, Montreal. Besides conducting a consulting practice of his own, Mr. Lea is associated with H. C. Ferguson, 200 Fifth Avenue, New York City, under the name of Lea and Ferguson, consulting engineers for paper and pulp mill equipment and hydraulic developments.

MR. ALEXANDER LESLIE BLACK has recently joined the firm of Ford, Bacon and Davis, 115 Broadway, New York, as engineer in charge of southern properties. Mr. Black graduated from the School of Mines, Columbia College, in 1890, leaving the college to go into mining work in Mexico. In 1894-5 he had charge of the reconstruction for electric operation of the St. Charles Street Railway, New Orleans, remaining with that company until 1901. Since that time he has been the engineer for the New Orleans Railway and Light Company.

◆

OBITUARY.

MR. H. J. BEEMER is dead in England, according to a cable despatch. Mr. Beemer was born at Holmesdale, Pennsylvania, in 1848. He began business in New York with Smith and Ripley, who brought him to Canada over twenty years ago. His first work as a contractor was on the Ottawa Railway bridge, followed by portions of the Dufferin improvements at Quebec. Later, he constructed a number of railways, bridges and waterworks. He built the Canadian Pacific Railway bridge at Ottawa, the Ottawa and Gatineau Valley Railway, the Pontiac and Pacific Junction Railway, the Quebec and Lake St. John Railway, the Quebec and Montmorency Railway, now the St. Anne division of the Quebec Railway, the Light, Heat and Power Company's system in Quebec, a new water main for the city of Quebec, and the new St. Louis and Kent gates, also in Quebec.

◆

MEETINGS.

The twelfth annual meeting of the Union of Canadian Municipalities will be held at Windsor, Ont., on August 27th, 28th and 29th. Among the speakers and their subjects are the president, Mr. J. W. McCready, Fredericton; Ald. Harris, Halifax, "Capital Cities"; City Engineer Doarn, Halifax, "The Cleaning of Water Mains"; Ald. Cannon, Quebec, "Electric Franchises"; Mayor Hebert, Sherbrooke, "The Operation of Public Utilities in Sherbrooke"; Ald. Boyd, Montreal, "Metropolitan Parks"; Mayor Hopewell, Ottawa, "The Georgian Bay Canal Water Powers"; S. Morley Wickett, Toronto, "Municipal Government by Commission"; G. A. Walters, Detroit, "Motion Pictures"; Controller Harvey, Winnipeg, "The Price of Cement"; Controller Cockburn, Winnipeg, "Winnipeg's Hydro-Electric Power Plant"; J. N. Bayne, Regina, "Municipal Progress in the West"; Mayor Spencer, Medicine Hat, "Good Roads and Their Effect Upon Rural Life"; Ald. Clarke, Edmonton, "Equable Municipal Taxation"; Ald. Hepburn, Vancouver, "Municipal Taxation"; Councillor Richardson, Point Gray, B.C., "Point Gray as a Model City."

◆

CANADIAN FORESTRY ASSOCIATION CONVENTION.

Mr. James Lawler, of Ottawa, secretary of the Canadian Forestry Association, has just returned from Montreal and the city of Quebec, where he was making arrangements for the Dominion Forestry Convention to be held upon the invitation of the government of British Columbia, in Victoria, B.C., on September 4, 5 and 6. He found great interest being taken in this convention, in which Sir Richard McBride and Hon. W. R. Ross will personally take part, and which will be held in the best time to see the Pacific Coast and the prairies. Hon. Jules Allard, Minister of Lands and Forests for Quebec, has consented to attend and he will be accompanied by some of the officers of his department. Eastern lumbermen and forest engineers will also be well represented. The railways have granted greatly reduced rates for the return trip to Victoria to delegates. Mr. Lawler, who is looking after the arrangements, states that everything is looking well for one of the largest conventions ever held on the coast.

◆

AMERICAN ROAD BUILDERS' ASSOCIATION CONVENTION.

The invitation extended by the mayor and the Commercial Association of the city of Cincinnati to the American Road Builders' Association to hold its ninth annual convention in that city has been accepted. The convention of the American Good Roads Congress, which is always held in connection with the convention, will, therefore, be held in Music Hall, Cincinnati, December 3, 4, 5 and 6.

In connection with the annual convention of the association, there will be held, as usual, an exhibition of machinery, materials and methods of road construction in Music Hall in space which has been set aside for the purpose. The building has a floor space of over 50,000 square feet and it is expected that all this space will be required for the exhibits. Not only will the manufacturers of material and machinery be represented in this exhibition, but the several states will have booths set aside for them in which they will exhibit models of roads, photographs, drawings, road materials, etc. This feature will be especially attractive to road builders. It is proposed, in fact, to make the exhibition practically an exposition of everything that pertains to road building and street paving in all their phases.

The American Road Builders' Association was organized in 1902. The president of the association is Nelson P. Lewis, chief engineer, Board of Estimate and Apportionment of New York city; first vice-president, Harold Parker, ex-chairman of the Massachusetts State Highway Commission; treasurer, Major W. W. Crosby, consulting engineer of the Maryland State Highway Commission; secretary, E. L. Powers, editor and publisher of "Good Roads." Among the directors of the association are: W. A. McLean, provincial engineer of highways of Ontario; Arthur W. Dean, chief engineer, Massachusetts Highway Commission; S. D. Foster, chief engineer, State Highway Department of Pennsylvania; W. J. Roberts, State Highway Commissioner, of Washington; James H. MacDonald, State Highway Commissioner, of Connecticut; Austin B. Fletcher, State Highway Engineer, of California; John R. Rablin, chief engineer, Metropolitan Park Commission, of Boston; R. A. Meeker, State Highway Engineer, of New Jersey, and Wm. H. Connell, chief of the Bureau of Highways and Street Cleaning, of Philadelphia.

While the association is made up primarily of technical men, everyone interested in street and highway improvement is made welcome at its meetings.

COMING MEETINGS.

THE WESTERN CANADA IRRIGATION ASSOCIATION.—Sixth Annual Convention at Kelowna, Okanagan Valley, B.C., August 13, 14, 15 and 16, 1912. Secretary, Normon S. Rankin, P.O. Box 1317, Calgary, Alta.

THE UNION OF CANADIAN MUNICIPALITIES.—August 27, 28 and 29. Meeting at City Hall, Windsor, Ont. Hon. Secretary-Treasurer, W. D. Lighthall, K.C.

CANADIAN FORESTRY ASSOCIATION.—Convention will be held in Victoria, B.C., Sept. 4th-6th. Secy., James Lawler, Canadian Building, Ottawa.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Second Annual Meeting to be held in Toronto, Sept. 16, 17 and 18.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Annual Assembly will be held at Ottawa, in the Public Library, on 7th October, 1912. Hon. Sec'y, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

EIGHTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.—Opening Meeting, Washington, D.C., September 4th, 1912. Other meetings, Business and Scientific, in New York, beginning Friday, September 6th, 1912 and ending September 13th, 1912. Secretary, Bernhard G. Hesse, Ph. D., 25 Broad Street, New York City.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Ninth Annual Convention will be held in Cincinnati, December 3, 4, 5 and 6, 1912. The Secretary, 150 Nassau St., New York.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, Mr. Hugh B. Fergusson, 409 Carter Cotton Bldg., Vancouver, B.C. Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address, P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack. Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION.—President, Mayor Lees, Hamilton, Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, [illegible] Indian Head, Sask.; Secy-Treasurer, E. Hingley, [illegible]

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta.; Secy-Treasurer, [illegible], Alta.

THE UNION OF CANADIAN MUNICIPALITIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, [illegible]; Hon. Secretary-Treasurer, J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, [illegible]; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, [illegible] Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, Mayor Mitchell, Calgary; Secretary-Treasurer, [illegible], Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewit, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President, J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Jas. Anderson, Gen. Mgr., Sandwich, Windsor and Amherst Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, A. F. Wickson; Toronto. Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Hon. W. R. Ross, Minister of Lands, B.C. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phoenix Block, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only, unless otherwise noted, at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close		Noted in issue of
8-5	—Electric Generating Machinery, Canora, Sask (S.)	7-18

(Canora specifications are also on file at the office of The Canadian Engineer, Rooms 617-628, Transportation Building, Montreal.)

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

Place of Work.	Tenders Close.	Issue of.	Page.
Canora, Ont., electric generating machinery	Aug. 5.	July 18.	78
Cobourg Harbor, Ont., breakwater	Aug. 14.	July 25.	68
Edmonton, Alta., gas holder and tank	Aug. 9.	July 4.	67
Edmonton, Alta., gas plant	Aug. 23.	July 18.	67
Kirkfield Park, Man., incinerator	Aug. 8.	July 18.	78
Northern Ont., right to cut pine.	Oct. 1.	July 25.	68
Norway House, Man., school and hospital	Aug. 19.	July 11.	68
Norwood, Ont., drill hall	Aug. 6.	July 25.	(2) 68

Ottawa, Ont., design for monument	Oct. 1.	Apr. 18.	60
Ottawa, Ont., supply of coal	Aug. 28.	July 25.	67
Pas Reserve, Sask., school building	Aug. 19.	July 11.	68
Regina, Sask., electrical plant.	Aug. 14.	July 25.	68
Toronto, Ont., drip guards	Aug. 13.	July 25.	68
Winnipeg, Man., 36-inch pipe	Aug. 28.	July 25.	68
York Township, concrete sidewalks	Aug. 5.	July 25.	68

TENDERS.

County of York, Ont.—Sealed tenders will be received by Frank Barber, county engineer, 57 Adelaide Street East, Toronto, up to noon Saturday, August 10th, for the construction of concrete bridges in this county. (See advt. in this issue of the Canadian Engineer.)

Dorval, P.Q.—Separate sealed tenders endorsed "Tender" will be received by A. Decary, town secretary, up to 4 o'clock p.m., August 15th, 1912, for the construction of water works, sewage system, and electric light installation. Plans and specifications may be seen at the office of the Town Engineer, Mr. V. H. Dupont, 62 St. James Street, Montreal.

Edmonton, Alta.—Sealed tenders marked "Tenders for steam heating, plumbing and sheet metal work in the Government House," will be received by John Stocks, Deputy Minister of Public Works, until noon August 7th, 1912. Plans, etc., may be seen at the structural engineer's office, New Parliament Buildings, Edmonton.

Lethbridge, Alta.—Tenders are asked for the erection and completion of St. Patrick's Church in accordance with plans and specifications prepared by E. C. Hopkins, Edmonton, and to be delivered to him on or before Wednesday the 7th of August next. Drawings and specifications can be obtained from H. M. and W. A. Whiddington, architects, Lethbridge.

Moose Jaw, Sask.—Tealed tenders marked "Tenders for Switchboard," addressed to the City Commissioners, Moose Jaw, will be received up to 12 o'clock noon on Friday, August 9th, 1912, for the supply and erection of one twelve panel switchboard.

Moose Jaw, Sask.—Sealed tenders marked "Tenders for reinforced concrete dam and highway bridge," addressed to the City Commissioners, Moose Jaw, will be received up till twelve o'clock noon on Friday, Aug. 9th, 1912, for the construction of one concrete dam and highway bridge across the Moose Jaw River. Plans, specifications and all information may be obtained from J. Antonison, City Engineer.

Niagara Falls, Ont.—Sealed tenders will be received by the National Trust Company, Toronto, up to and including the fifteenth day of September, 1912, for the purchase of the property heretofore owned and operated by the Canadian Ethinite Company, Limited, and by the Canadian Calcium Carbide, Limited, and also for the purchase of certain patents owned by the Canadian Ethinite Company, Limited.

Ottawa, Ont.—Sealed tenders addressed to R. C. Desrochers, secretary Department Public Works, and endorsed "Tender for wharf at Kempenfeldt Bay, Ont.," will be received at this office until 4 p.m. on Wednesday, August 21, 1912, for the construction of a wharf and approach at Kempenfeldt Bay, on Lake Simcoe. Plans, specifications, etc., can be seen at this department and at the offices of J. G. Sing, Confederation Life Building, Toronto; and at the post office at Painswick, Ont.

Ottawa, Ont.—Sealed tenders addressed to R. C. Desrochers, secretary Department of Public Works, and endorsed "Tender for the repair of headblock at Port Colborne, Ont.," will be received at this office until 4 p.m., on Wednesday, August 21, 1912, for the repair of the headblock of the east breakwater, at Port Colborne, County of Welland, Ont. Plans may be seen at the office of J. G. Sing, Confederation Life Building, Toronto, and at this department.

Ottawa, Ont.—Sealed tenders addressed to J. D. McLean, assistant deputy and secretary Department of Indian Affairs, and marked on the envelope, "Tender for school building, Cape Croker Indian Reserve," will be received up to noon of August 26, 1912, for the erection of a stone school house and teacher's residence combined on the Cape Croker Indian Reserve.

Ottawa, Ont.—Tenders addressed to W. W. Cory, deputy minister of the Department of the Interior, Ottawa, Ont., marked "Tender for wire fence," will be received up to 12 o'clock noon of the 20th August, 1912, for the construction of a wire fence around Moose Mountain Buffalo Reserve.

Ottawa, Ont.—An extension of time for the sending in of the sketch models for the competition for the memorial to his late Majesty King Edward VII., has been granted. The designs must be delivered at the National Art Gallery of Canada, Victoria Museum, Ottawa, before the 1st day of November, 1912.

Ottawa, Ont.—Sealed tenders, addressed to R. C. Desrochers, secretary Department Public Works, and endorsed "Tender for breakwater, sheet piling and dredging at Beaverton, Ont.," will be received at this office until 4 p.m. on Monday, August 26, 1912. (See advt. in Canadian Engineer.)

Ottawa, Ont.—Tenders addressed to John McDougald, Commissioner of Customs, will be received up to noon of the second day of September, 1912, for the construction of a twin screw steel steamer for Customs service on the Atlantic coast, to be delivered at the port of Quebec.

Ottawa, Ont.—Sealed tenders addressed to R. C. Desrochers, secretary department of public works, and endorsed "Tender for addition to wharf at Murray Bay, P.Q.", will be received until 4 p.m., on Wednesday, August 7, 1912, for the construction of an addition to the wharf at Murray Bay, County of Charlevoix, P.Q.

Port Arthur, Ont.—Messrs. Hood and Scott, architects, are calling for tenders for the construction of the new public library. The estimated cost of this work is $35,000.

Toronto, Ont.—Sealed tenders endorsed "Tenders for Dormitory," addressed to H. F. McNaughten, secretary Department of Public Works, Ontario, will be received at this department up to noon on Thursday, the 8th day of August, for the erection of dormitory buildings on the grounds of the Institution for the Blind, Brantford. Plans and specifications can be seen at this department and at the above institution.

Streetsville, Ont.—Tenders will be received by S. P. Smith, town clerk, up to Aug. 5th, 1912, for the following:

(a) For excavating, laying and back filling of 4,115 ft. of 6-inch water pipe; top of pipe to be 4½ ft. from ground level, the packing of joints, attaching hydrants and T. Tenders to state price per running foot for the same.

(b) Twenty hydrants, complete, f.o.b., Streetsville. Hydrants to be similar to one in use at present.

(c) Excavating and back filling for 4,115 feet; depth 5 feet.

(d) Packing of joints, laying pipe, attaching necessary hydrants and T.

(e) For 4,115 feet of cast iron pipe, 6-inch; weight not less than 30 lbs. to foot; also two T's with cap, to be tapped for 4-inch pipe. All f.o.b. Streetsville.

(f) Tenders will also be received for the work complete.

Toronto, Ont. — Tenders will be received by W. H. Hearst, Minister of Lands, Forests and Mines, up to and including the 15th day of August next, for the right to cut pulpwood on a certain area situated on the Abitibi Lakes and River, tributary to the Grand Trunk Pacific Railway, and the Temiskaming and Northern Ontario Railway, in the District of Temiskaming.

Victoria, B.C.—Sealed tenders will be received by W. Galt, municipal purchasing agent, up to 3 p.m. on Monday, Aug. 5, 1912, for the supply of 12,000 feet; 10 pair No. 16 electric cable; 2,000 feet No. 16 Duplex cable; 10 miles No. 12 W.P.B. and S. gauge steel wire.

Winnipeg, Man.—Sealed tenders addressed to the chairman, Board of Control, will be received by M. Peterson, secretary, up to 11 a.m. on Monday, August 5th, 1912, for supply of 5,000 Tobin bronze bolts, ⅞-inch diameter and 3¼-inch in length.

◆

CONTRACTS AWARDED.

Brandon, Man.—The contract for the structural steel work of the new arena of the Brandon Winter Fair was let to the Wisconsin Steel and Iron Company of Chicago, and the contract for the completion of the work has just been given to C. W. Hall, of Brandon.

Brockville, Ont.—The Board of Works has awarded the contract for the paving of King Street to the Godson Contracting Company of Toronto, on the following terms:

Asphalt pavement, [illegible] per square yard.

Concrete curb and gutter, 70c. per foot.

Earth excavation, [illegible] per cubic yard.

Rock excavation, [illegible] per cubic yard.

Dutton, Ont.—The section of the main line from the [illegible] on the south side of the town hall lot, [illegible] feet, has been given to [illegible] for [illegible]. The village will provide the material.

Guelph, Ont.—Messrs. P. H. Secord and Sons have been awarded the contract for excavating and the concrete base, [illegible] per square yard. The city engineer will lay the Tarvia wearing service at [illegible] cents per square yard.

Fort William, Ont.—The contract was awarded to Barrett and McQueen of this city for the construction of the new Fort William Elevator Company grain house. The contract price was close to [illegible].

Fort William, Ont. — The Canadian Stewart Company have been awarded the contract calling for the erection of a grain elevator for the Superior Elevator Company of Winnipeg, Man.

Port Arthur, Ont.—The contract for the paving of Cumberland Street has been awarded to the Warren Bituminus Paving Company and the National Paving Company of Winnipeg have been awarded the contract to lay a coating of asphaltic concrete on Algoma Street.

Port Arthur, Ont. — Barrett and McQueen have been awarded the contract for construction of grain elevator for the Fort William Elevator Co.; capacity, 3,000,000 bushels. Approximate amount of contract, $700,000.

Port Colborne, Ont.—The contract for the extension of the piers to provide additional docking facilities has been awarded to M. J. Hogan at a price of $213,000.

Regina, Sask.—Messrs. Wilson and Wilson have been awarded the contract for erecting the addition to the collegiate institute. This is to be a ten-roomed structure and the price agreed upon is $88,500. Other bidders and their prices were: R. J. Lecky and Co., $109,962; Parsons Building Co., $95,580; Smith Bros. and Wilson, $90,000; Wilson and Wilson, $88,500.

Sherbrooke, P.Q.—Messrs. Lefebore and Bonin, architects and builders, have been awarded the contract to erect a convent 132 x 50, brick stone foundation. The price for this work is $37,000.

Sherbrooke, P.Q.—Messrs. Loomis Dackin, Ltd., have been awarded the contract to erect a building, excluding the steel work, for the Bank of Montreal. The price for this work is placed at $40,000. The steel work has been awarded to MacKinnon, Holmes and Company, Ltd.

St. Catharines, Ont.—Thos. E. Riloy has been awarded the contract for the construction of the new trunk sewer.

Vancouver, B.C.—The Board of School Trustees awarded the contract for the erection of the Dawson School to the Canadian Ferro Concrete Company at a price of $121,913.

Vancouver, B.C.—D. Matheson has been awarded the contract calling for the erection of a set of stone steps at the King Edward High School. The price for this work is $3,397.

Winnipeg, Man.—The G. M. Gest Company have been awarded a contract to construct an electric cable conduit on Portage Avenue from Carlton Street to Sherbrooke Street.

◆

RAILWAYS—STEAM AND ELECTRIC.

Fredericton, N.B.—The Minister of Railways and Canals has concluded the purchase of several pieces of property with the intention of starting work on an improved station yard for the Intercolonial Railway.

St. Thomas, Ont.—The deficit in the street railway in 1910 was $12,044.44 and in 1911 $10,537.48, a decrease of $2,406.96.

◆

LIGHT, HEAT AND POWER.

Edmonton, Alta.—The municipal council will discuss a communication received from the provincial authorities regarding an application of The Western Power Joint Stock Company, Ltd., to erect poles and offer power for sale in opposition to the municipal plant in this city.

Kingston, Ont.—The Seymour Power Company purposes making another proposal to supply power to Kingston and it has had experts here looking over the ground, so that the offer will be as fine as can be drawn.

Moncton, N.B.—The Board of School Trustees has entered into an agreement with Moncton Tramways, Electricity and Gas Company to heat two schools with gas. The agreement contains a clause providing that should the expense of this be higher than the cost of similar heating with coal the company will reimburse the Board.

Barrett Specification Roofs

The Place to Break the Pen!

The building shall be covered with a Barrett Specification Roof or

IN writing your roofing specifications it is especially important not to add "or equal thereto."

You need precision in dealing with a roof more than with any other part of the structure for the reason that in laying a roof there are many opportunities for "skinning the job."

Further, you put the honest, reliable contractor at a great disadvantage when you ask him to bid on an indefinite or vague specification, and such specifications usually mean poor workmanship and cheap materials with subsequent leaks and trouble.

There are various ways of constructing gravel and slag roofs, but if The Barrett Specification is followed, there is no chance for mistakes or slipshod workmanship.

It describes in a practical way how to use Specification Felt and Specification Pitch to make a first-class roof—one that will always give maximum service.

The Barrett Specification embodies the best experience of the roofing industry and is designed for the benefit of architects, engineers and owners.

Incorporate it in full into your own building specification and you will be ordering a roof that has shown a lower cost per foot per year of service than any other type of roofing ever made.

We know that if all buildings were covered with Barrett Specification Roofs, roof troubles would be practically nil.

Copy of the Barrett Specification ready for incorporation into building specifications free on request.

Special Note

We advise incorporating in plans the full wording of The Barrett Specification, in order to avoid any misunderstanding.

If an abbreviated form is desired, however, the following is suggested:

ROOFING—Shall be a Barrett Specification Roof laid as directed in printed Specification, revised August 15, 1911, using the materials specified, and subject to the inspection requirement.

THE PATERSON MANUFACTURING CO., LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER ST. JOHN, N.B. HALIFAX, N.S.

Orillia, Ont.—The Town Council have re-leased the Ragged Rapids from the Department of Lands, Forests and Mines for a period of ten years. The town is to pay the government a rental of fifty cents per horse power per year on a basis of 1,600 h.p.

Regina, Sask.—The municipal engineer has reported to the council that the recent cyclone caused $9,775.85 damage to the electric light plant.

Vancouver, B.C.—The municipal council have received the following tenders for the installation of electric or steam equipment for the rock and gravel bunkers at Bridge Street: B.C. Equipment Company, $2,086, $5,156 and $5,198; R. Hamilton and Company, $2,936 and $3,010; Pacific Machinery and Supply Company, Limited, $9,869; Mussens Limited, $6,876 and $6,047; Vancouver Machinery Depot, $3,380 and $4,220.

Victoria, B.C.—The municipal council have opened the following tenders for the installation of an arc light system: Hinton and Company, $13,195; Messrs. Hutchison Bros., $10,350; Electrical Construction Company, $10,500.

Winnipeg, Man.—A report states that the new conduits to be laid on Portage Avenue will contain accommodation for all the wires now carried on poles.

◆

GARBAGE, SEWAGE AND WATER.

Galt, Ont.—The municipal council have received a notice from the provincial authorities which will call for considerable work in connection with the treatment of the town's sewage discharge. They will have to abandon the present method of utilizing the river for this purpose and erect sewage tanks, etc., that have the approval of the board.

Imperial, Sask.—This place intends to proceed with installation of water works. J. G. Hobman, secretary-treasurer.

Ingersoll, Ont.—A by-law calling for the expenditure of $57,000 on a sewerage system was defeated by the ratepayers with a majority of 390.

Lacombe, Alta.—A petition made by the council shows that 80% of the ratepayers are in favor of the installation of a waterworks system.

Medicine Hat, Alta.—The ratepayers will vote on August 18th next on the matter of spending $300,000 on a new system of water works.

St. Thomas, Ont.—The water commission has a surplus revenue of $[illegible].

Winnipeg, Man.—The chairman of the Provincial Board of Health, Dr. R. M. Simpson, has warned the municipal council regarding the evident signs of failure on the part of the water supply of this city.

Winnipeg, Man.—Dr. Simpson, chairman of the provincial health board, has condemned Winnipeg's present water supply, both in quality and quantity. He advised against an extension of the present artesian well supply and for a visible supply.

Yorkton, Sask.—Mr. R. O. Wynne-Roberts, Regina, has made a report for this municipality regarding the future source of supply and intimates that the ratepayers need not feel anxiety as an abundant supply is available from certain springs in the vicinity of the town.

◆

BUILDINGS AND INDUSTRIAL WORKS.

Canning, N.S.—The management of the Cornwallis [illegible] Company will [illegible] [illegible] building [illegible] feet.

Edmonton, Alta.—Plans are prepared for the erection of [illegible] for the Grand Trunk Pacific Railway call for an expenditure of $[illegible]. [illegible]

Fredericton, N.B.—Messrs. W. M. Jones, Thomas Mc[illegible] [illegible] and Charles S. [illegible] are seeking incorporation as The New Brunswick [illegible] Co., Ltd., with a capital of $[illegible]. [illegible]

Fredericton, N.B.—The municipal council will consider plans for the erection of a new fire hall. Ald. Cruikshank is chairman of a committee dealing with the matter.

Fort William, Ont.—A permit has been issued to the Canadian Pacific Railway for the erection of a gas plant to supply illuminating gas to the cars.

Guelph, Ont.—The management of the Guelph Carpet Mills Company will again enlarge their plant. This time a brick building, 130 x 50 feet, will be located in the rear of the present plant.

Medicine Hat, Alta.—Mr. F. P. Jones, of the Canada Cement Works, is considering the establishment of a cement works in this city.

Medicine Hat, Alta.—Mr. W. J. Christie, of Winnipeg, Man., is making arrangements for the erection of a glass plant in this city.

Montreal, P.Q.—Plans are now being prepared under the supervision of Mr. R. L. Deschamps, of the Public Works Department, for a new terminal warehouse for the Customs Department. It will be seven stories high and will cost at least $750,000. Tenders for the construction of the building will be called in a few days.

Moose Jaw, Sask.—The Minister of Militia has signified his intention of erecting a $100,000 armory in this city.

Provnce of British Columbia.—The Cowichan Lake Lumber Company is planning to erect a sawmill at the lake and another one later on at a site already secured in the vicinity of Port Moody.

Quebec, P.Q.—Arrangements are under way for the erection of an arena in this city. In size it will be 268′ x 162′. The architects are Messrs. Ross and MacFarlane, Montreal.

Regina, Sask.—The Loyal Order of the Moose have purchased a plot of ground in this city with the intention of erecting a seven story building. A building committee has been formed with Mr. R. P. Allen, of the Western Construction Company, as chairman.

Stratford, Ont.—The International Mausoleum Company of Toronto have purchased a perpetual lease of one acre of land in the local cemetery and will start work on a stone and marble mausoleum similar to the one recently constructed in Toronto, but on a smaller scale. The cost of this work is estimated at $125,000.

Victoria, B.C.—A report is in circulation to the effect that Maclaren cheese manufacturers are considering the location of dairying plants in the vicinity of this city.

Victoria, B.C.—A new block is projected for the corner of Hillside Avenue and Douglas Street, having a frontage of 144 feet on Douglas Street and 120 on Hillside Avenue, for R. Scott. L. W. Hargreaves being the architect.

Welland, Ont.—A report states that the Northern Steel Company will erect a rolling mill 150 by 600 feet and 85 feet high, to roll black plate and sheets, and other smaller buildings will be erected. Construction work is to be started at once and the plant will open early next year with 500 employes, running eight-hour shifts, 24 hours daily.

◆

BRIDGES, ROADS AND PAVEMENTS.

Guelph, Ont. — The commissioners have recommended that paving be commenced on Wilson and Sandiland Streets and the space in front of the fire hall. The city will put the surface of tar macadam on.

Locust Hill, Ont.—The bridge crossing the Little Rouge was demolished by an overload.

Moose Jaw, Sask.—The members of the Railway Commission have given a decision which calls for the construction of a bridge over the Canadian Pacific Railway tracks. The city are to pay $[illegible] towards the cost and maintain the road.

New Westminster, B.C.—The municipal council are considering by-laws, amounting to $[illegible], for additional street paving, grading and widening.

Ottawa, Ont.—A report states that there is a likelihood of a bridge being constructed over the Rideau at Gladstone Avenue.

AGENTS FOR CANADA LAURIE & LAMB, ENGINEERS, MONTREAL

Peterboro, Ont.—A conference has been held in connection with the matter of erecting a bridge across Pigeon Creek. This is between the counties of Peterboro and Victoria and it is probable that government aid will be asked in the project.

Province of Alberta.—The Privy Council has decided a suit regarding the building of bridges over the irrigation canal in favor of the province.

Ottawa, Ont.—It is the intention of the city engineer to carry the garbage to the new incinerator by the cars of the Grand Trunk Railway.

St. Catharines, Ont.—The council have passed a by-law calling for the erection of a concrete bridge across the Welland Canal at a cost of $75,000.

Vancouver, B.C.—The municipal council have received the following tenders for the creosoted wood block pavement of Broadway: Laplaca Brothers, $47,636; Romano Pinto and Company, $47,800; and Bruce and Ford, $49,500. For resurfacing Main Street with wood blocks and stone in the track, the following were the tenders: T. R. Nickson and Company, $12965; Romano Pinto and Company, $12,700; and Laplaca Brothers, $10,349.

Victoria, B.C.—The municipal council have sent out notices of their intention to grade, drain and pave a number of streets.

◆

FIRES.

Dundas, Ont.—The factory and plant of Messrs. Jones Brothers was destroyed by fire with a loss of about $25,000. The firm manufactures dental and barbers' supplies, bar fixtures and interior shop and office fittings.

Montreal P.Q.—The mattress factory of B. Simon and [illegible] was damaged by fire to the extent of $2,000.

Montreal, P.Q.—The plant and stock of the Sovereign Lime Works was destroyed by fire with an estimated loss of $80,000. Mr. A. N. Tessier is the managing director.

◆

CURRENT NEWS.

Fort William, Ont.—The city engineer, Mr. John Wilson, has been given permission to engage an assistant and pay up to $150 per month for a suitable man. It is probable that this will be a temporary appointment.

Hamilton, Ont.—A survey of this port will be made by the Harbor Commission. The municipal council will defray the expense and a surveyor will be appointed at once, and make a grant of $500 toward office expenses and the engagement [illegible]

Ingersoll, Ont.—A by-law to vote a sum of money to assist a local manufacturing concern and a by-law to erect certain local improvements were defeated by the ratepayers.

Norwood, Man.—The Consumers Ice Company has been organized with the intention of erecting a plant in this place. Many Winnipeg men are interested in the project. Among the [illegible] W. S. Thomson, president [illegible] A. J. Andrews, vice-president; F. E. Cryder, managing director; J. R. Forman, secretary-treasurer; Dr. E. A. Jones. The pro- [illegible] tural artesian water under the Harrison process which is in [illegible] United States. [illegible]

Ottawa, Ont.—[illegible]

[illegible]

Ottawa, Ont.—The government has invited tenders for the construction of the new car ferry, which will be plied in the service between the mainland and Prince Edward Island. Tenders have been invited in Canada, the United States, Great Britain, Germany and Denmark. Specifications for the ferry are to be furnished and tenders will close August 15th. It is to be hoped to have the new ferry in operation this winter, if at all possible.

Quebec, P.Q.—The Federal Government has given up the idea of piercing a tunnel under Cape Diamond in order to have a union station in the Palace Ward, and its decision is to build the Transcontinental terminals, elevators and car ferry service on the water front, together with the station, on the old site of the Champlain market.

Regina, Sask.—The municipal commissioners are making preliminary plans for the erection of a gas plant next year.

Toronto, Ont.—There is a probability of friction arising between the gas company in this city and the Municipal Parks Department owing to the alleged destruction of some fine elm trees by the laying of gas mains.

Toronto, Ont.—The directors of the university have recently awarded a contract for 9,000 tons of soft coal to be used in the boilers of the heating plant during the coming winter. It is the intention of the directors to install proper smoke consuming appliances as the Queen's Park, where the university is located, is also the residence of many wealthy citizens.

Toronto, Ont.—The yards of the Polson Iron Works present a busy aspect at the present time; several tugs and some larger vessels are under construction.

Vancouver, B.C. — The municipal council has ordered that all sawmills be equipped with proper saw dust burners by January 1st next. This is the outcome of an action on the part of the council to lessen the smoke nuisance.

Winnipeg, Man.—The Board of Control invites architects resident in Canada to submit designs from which a selection may be made of a plan for the erection of a new City Hall for the city of Winnipeg (estimated cost $3,000,000). A copy of the regulations and conditions embodied in the programme governing the competition may be obtained from M. Peterson, secretary, Board of Control.

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada 17 Victoria Street, London, S.W., during the week ending July 15th, 1912:—

A London firm is in the market for supplies of Canadian three-ply veneer.

A Welsh firm of bituminous paint manufacturers desire to get into touch with Canadian importers.

A London firm are in the market for Canadian mica. and would like to hear from actual mine owners in the Dominion.

The commercial manager of an English firm manufacturing a patent lighting system is about to visit Canada with a view to appointing agents in each province.

From the branch for City Trade Inquiries, 73 Basinghall Street, E.C.:

A firm of commission merchants in Johannesburg wish to get into communication with Canadian shippers of planks and other lumber suitable for South African markets.

A London firm would be pleased to hear from Canadian manufacturers of fence wire, wire netting, and also wire nails, who are in a position to undertake export trade.

A French firm wish to arrange for the sale in Canada of a patented automatic machine for making bottles.

A Glasgow engineering firm who are sending out a representative to Canada next month would like to hear from United Kingdom machinery manufacturers seeking Canadian representation.

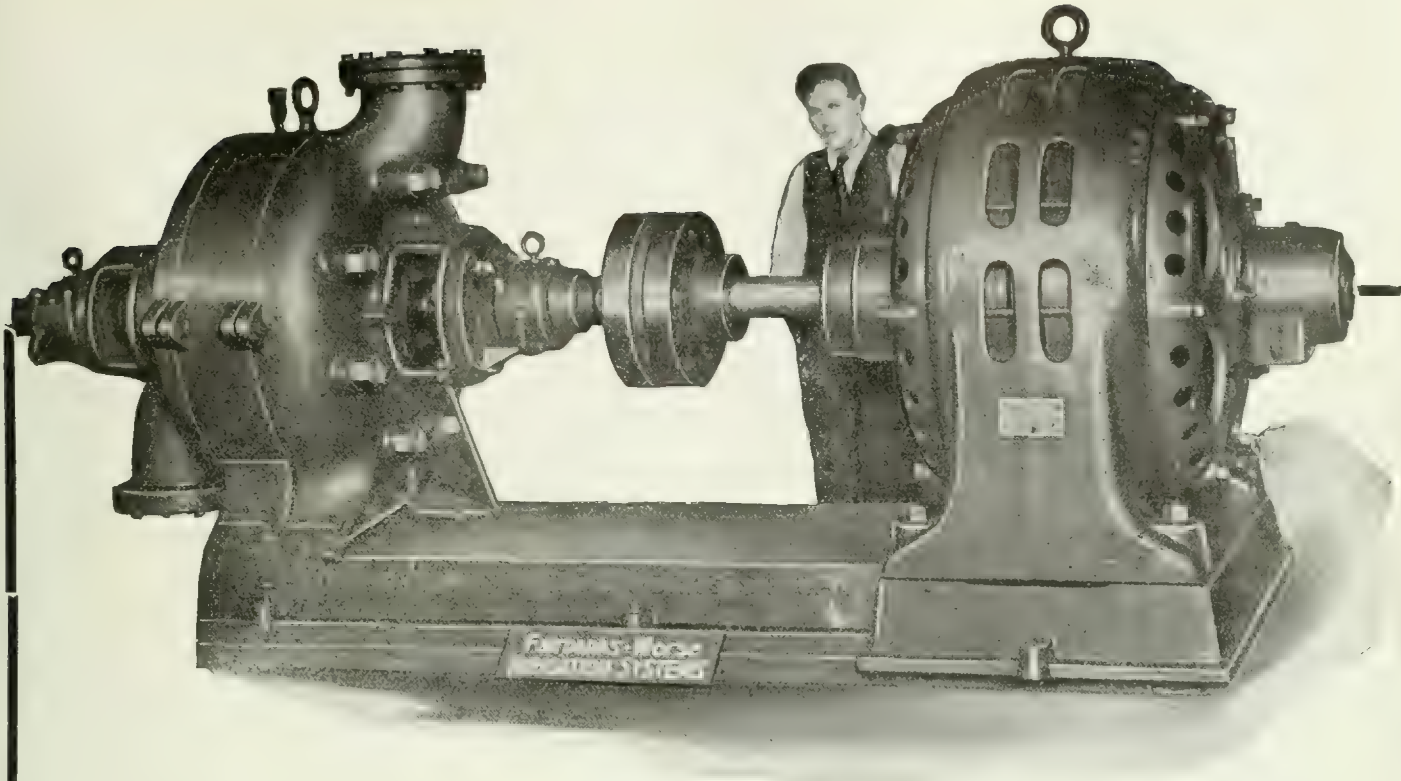
COPIES OF CANADIAN ENGINEER WANTED.

One copy each of our issues of July 4th and 11th are required at once. The usual extension of the sender's subscription will apply in this case.



The Largest Direct Connected Centrifugal Pumping Unit in British Columbia.

The Vancouver Power Company have recently installed at their works at Coquitlam Dam, B.C., the largest direct connected centrifugal pumping unit in British Columbia. This outfit is to operate in parallel with a number of other pumps that are to furnish water under pressure for sluicing into place the material for their new dam.

This pump is a 10-inch, class "F," two-stage centrifugal, with bronze inpellers and renewable bronze diffusion vanes. It has a normal capacity of 1833 imperial gallons per minute when operating at 1160 r.p.m. against a total head of 355 feet or an equivalent pressure of 154 lbs. per square inch. It is mounted on a common sub-base with a 300 h.p. type "B," Fairbanks-Morse squirrel cage, induction motor, 2200 volts, 60-cycle, 3-phase, 1160 r.p.m. at full load, being direct connected thereto by means of a flexible leather link coupling.

The motor possesses a feature in rotor construction that is unique. The end rings are welded on to the rotor bars by a new process, making a perfect joint, free from the troubles common to the purely mechanical or riveted joint, such as oxidation, working loose, and solder-throwing. This improvement marks a long step forward in the elimination of rotor trouble.

Our Vancouver Branch supplied and assembled this complete pumping unit. We are in a position to quote on the necessary equipment for any pumping requirements on receipt of specifications.

NEW BATHS IN CONNECTION WITH THE CANADIAN PACIFIC RAILWAY HOTEL AT BANFF.

There has recently been opened two new baths or swimming pools in connection with the hotel at this point. One fed by the sulphur springs is 24 feet wide by 75 feet long, while the fresh water pool is 90 feet across, receiving its supply from the mountain springs. There are 72 dressing rooms in connection with the pools. In addition, Turkish and Russian baths have been provided to which are attached 24 dressing rooms, containing every up-to-date appointment.

The swimming baths are constructed of reinforced concrete, and lined with white enamel tiles. The fittings are of the latest and most modern pattern every convenience having been provided. The sulphur pool is protected by a screen of plate glass with reinforced pillars, at the top of which have been arranged boxes containing mountain flowers. The fresh water pool is on a lower terrace, and above the sulphur pool is a fine promenade terrace connecting with the hotel.

16990—July 12—Approving plan of G.T.R. cross-over switch east end of Cardinal Yard, Ontario.

[illegible]—July 11—Authorizing G.T.P. B.L. Co. to construct industrial spur in Yorkton, Saskatchewan.

16998—July 13—Authorizing C.P.R. to construct spur near Longue Pointe, Que., and granting certificate of correction.

16999—July 15—17000—July 8—Authorizing C.P.R. to construct spur for Saskatoon Public School District Board, Saskatoon, Sask., and for Ogilvie Flour Mills Co., Ltd., Fort William, Ontario.

17001—July 8—Authorizing C.P.R. to construct spur for Messrs. McGregor & McIntyre, Lot 28, Con. 2, from Bay, Twp. of York, Ont.

17002—July 8—Authorizing Campbellford, Lake Ont., and Western Ry. to join its tracks at mileage 183.51 from Glen Tay with C.P.R. (O. & Q. Ry.) at mileage 87.41, westerly from Havelock, Ont.

17003—July 13—Authorizing Gedeon Mailloux to construct farm crossing on his farm across G.T.R. near mile-post [illegible] from Windsor, Ontario.

17004—July 13—Directing G.T.R. to install gates at crossing main street, Victoriaville, Que.,. within 60 days.

17005—July 13—Approving change in C.P.R. station building at St. Augustin, Que., County of Two Mountains.

17006—July 8—Authorizing C.N.O. Ry. to construct across public road in Parish of St. Genevieve, County Jacques Cartier, Que.

17007—July 13—Authorizing Empire Limestone Co., Ltd., to construct tunnel or cut under Carroll Brothers' siding in Lot 5, 1st Con. Twp. of Humberstone, County Welland, Ontario.

17008-9—July 8—Approving revised location Canadian Northern Ontario Railway through Twps. of Boulter, Lauder, Pentland, and Master, Stratton and Barron in District of Nipissing, Ontario.

17010—July 8—Authorizing Canadian Northern Ontario Railway to cross with its line public road between lots 5 and 6, Twp. of Ross, Ct. Renfrew, Ontario.

17011—July 8—Approving revised location Canadian Northern Ontario Railway in Twp. of Beaucage, District of Nipissing, Ontario.

17012—July 13—Authorizing Campbellford, Lake Ont. and W. Ry., (C.P.R.) to make changes in its line and cross Bay of Quinte Railway at mileage [illegible] in Twp. of Camden, Ct. Addington, Ontario.

17013—July 15—Approving changes in location Canadian Pacific Railway station at North Wakefield, Quebec.

17014-15-16—July [illegible]—Authorizing Canadian Northern Ontario Railway to cross public roads in Twps. of Bristol, Pontiac Ct., Quebec, and in Twp. Westmeath, Ct. Renfrew and in Twp. Torbolton, County of Carleton, Ontario.

17017—July [illegible]—Authorizing Grand Trunk Railway to construct spur for John Duff and Son, Hamilton, Ontario.

17018—July 16—Approving revised location of G.T.P.B.L. Co., mileage 26.26 to 38.74 Saskatchewan (Cutknife Branch).

17019-20—July 16—Authorizing G.T.P.B.L. Co., to construct spur for McLeod Collieries, Ltd., from its Alberta Coal Branch and Grand Trunk Pacific Railway to construct spur for Jasper Park Colliers, District of North Alberta, Alberta.

17021—July 16—Approving location Montreal and Southern Counties Ry. from Ranlagh to boundary between Parish of Longueuil and Parish of Laprairie, Quebec 4,500 feet.

17022—July 13—Directing Canadian Pacific Railway to within 90 days install electric bell at Queen Street, Woodstock, N.B., 20 per cent. from Grade Crossing Fund.

17023—Juy 16—Directing Temiscouata Railway to within 30 days remove cattle guard and earth at crossing of Grand Falls Road, under penalty of $25.00 per day.

[illegible]—Approving revised location Campbellford, Lake Ont. and W. Railway, mileage 155.13 (from Glen Tay) to mileage 157 and approving location through town of Whitby, Ont., and authorizing crossing of main line track and two additional tracks in 1st Con. of Twp. East Whitby, Ct. Ontario, Ontario.

[illegible]—Authorizing Canadian Pacific Railway to construct spurs for Fitzsimmons Fruit Co., Ltd., at Port Arthur, Ont. For Crow's Nest Pass Lumber Co., Ltd., at Calgary, Alta., for Rocky Mountains Cement Co., Ltd., at Blairmore, Alberta.

[illegible]—Approving Canadian Pacific Railway plans for span at eastbound hump, new yard, East Winnipeg, Man., and bridge 132.3 Brandon, S.D.

[illegible] Grand Trunk Railway and Canadian Pacific Railway to operate trains over interlocker at West of Fergus, Ont., without stopping.

[illegible]

[illegible] September, 1912, [illegible] new Union Station, Toronto, Ont., same to be commenced forthwith and [illegible] per day.

[illegible]

17036—July 11—Reserving for further consideration of Board approval [illegible] and author- [illegible] C.N.O. Ry.

An Engineering Weekly

THE HIGH TENSION TRANSMISSION SYSTEM OF THE HYDRO-ELECTRIC POWER COMMISSION OF ONTARIO.

THIRD ARTICLE.

Telephone System.

A private telephone system connects and provides a means of instant communication between the transforming stations of the system. The Niagara, Dundas, Toronto and London stations are what might be termed "terminal stations," since the telephone lines terminate on the individual drops in these exchanges, while Port Credit, Guelph, Preston, Berlin, Stratford, St. Marys, Woodstock and St. Thomas are through stations with exchanges bridged across the the main line and operated as party-line stations. All exchanges are located on a loop circuit and can be sectionalized without interfering with other exchanges by means of specially installed switches in case of trouble. The telephone circuits are erected on separate poles paralleling the high-tension system. Considerable inconvenience was at first experienced from induced potential on the telephone circuits, which was found to be sufficiently high to strain the insulation of the standard potential equipment beyond safe limits. Various types of protective equipment were at first employed, but were unsatisfactory. After careful consideration and study of the conditions and requirements, an entirely original equipment, designed by the engineers of the commission, was installed and the operation of the telephone system since then has been entirely satisfactory. The equipments (Fig. 21) are mounted on special slate panels and consist of indicating fuses, vacuum type lightning arresters, auxiliary gap arresters, specially wound open-core choke coils, accurately balanced bleeding inductances and condensers.

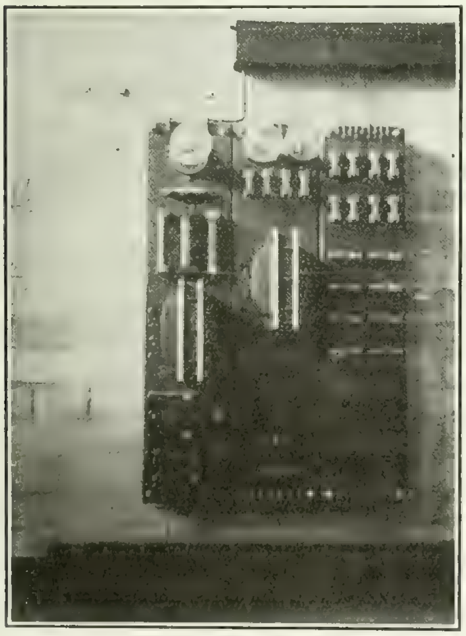

Fig. 21.—Telephone Protective Equipment Panel.

Description of Stations.

Niagara Falls Station.—Power is received at the Niagara Falls station (Fig. 22) from the Ontario Power Company's distributing station at a potential of 12,000 volts over three conductor, 300,000 cm., paper-insulated, lead-sheathed cables 2,200 feet in length, placed in tile conduits. Each cable has a carrying capacity of 4,500 kw., and since the individual transformer banks have a rating of 9,000 kw., the incoming power cables feeding these banks are connected in parallel. The ends of each pair of cables are protected by automatic oil circuit breakers connected to auxiliary buses, which in turn, are connected by similar breakers to the main buses, or directly to banks of transformers as desired.

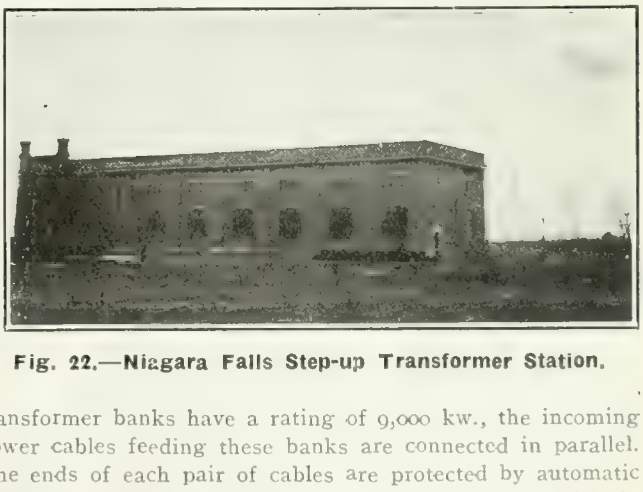

Fig. 22.—Niagara Falls Step-up Transformer Station.

At present there are nine 3,000 kv-a. single-phase transformers installed, although the building has been made sufficiently large to contain an additional bank of three.

From the high-tension side of the transformers the current is carried through disconnecting switches, and high-tension oil switches to the high-tension busbars, here it passes again through disconnecting switches and oil circuit breakers to the line outlets of the two 110,000 outgoing lines, and thence through choke coils and electrolytic arresters, provided with horn gaps placed outside, on to the line. (Fig. 23).

The 12,000-volt switches, busbars and accessories are located in the basement, and incoming feeder cables are laid in ducts beneath the basement floor, the necessary number terminating at the terminal compartment opposite each feeder switch. The heating boilers, oil tanks, storage battery, pumps and air compressor are situated in other parts of the basement. The cables feeding the switches terminate in terminal rooms with standards and bells, above which the feeders are tied together in pairs. The leads from the transformer oil switches pass up through the floor to the transformers, where the potential is stepped-up to 63,500 volts single-phase. Each feeder is equipped with three oil circuit breakers, the first connecting the power source to an auxiliary bus, the second, the auxiliary bus to the main bus, and the third, the auxiliary bus to a bank of transformers. By this arrangement a feeder, with a capacity equal to that of a transformer bank may be connected directly to a transformer bank or to the main bus. Through the medium of the auxiliary bus a transformer bank may also be connected to the main bus. This arrangement, while not complicated, offers sufficient flexibility to the circuit, since there are always two oil circuit breakers in series. The feeder switches are equipped with inverse time limit relays. The feeder switches are equipped with inverse time limit relays. Only the bus switches are non-automatic. Disconnecting switches are also supplied on both sides of the oil switches, which are electrically controlled from a switchboard located in the control room; colored lights being employed to indicate the position of the switches.

A service oil switch for controlling the transformers employed for the lighting, mechanical and other station equipment is connected to the 12,000-volt bus.

All 12,000-volt connections, busbars and switches are enclosed in compartments.

The transformers and high-tension switches are located on the main floor. Transformer banks are separated from [illegible]

through a water resistance. The nine 3,000-kv-a. transformers are shell type, oil-insulated, water-cooled, and designed for operation at a potential of 12,000 volts low-tension, and 110,000 volts high-tension. They are equipped with the Westinghouse condenser type of bushing. (Fig. 24).

The transformers and high-tension lines are connected to the buses by automatic three-pole oil circuit breakers, operated from the control gallery in a manner similar to the 12,000-volt oil switches. In general the oil switches are isolated by means of disconnecting switches with blades normally vertical, mounted on post insulators, supported on the walls. All 110,000-volt connections and buses consist of bare one inch seamless copper tubing installed near the roof and supported on porcelain petticoat insulators, of the built-up post type, with an over-all height of 39 inches, in turn secured to special steel structures. These buses extend the entire length of the high-tension switch room, and have a minimum clearance of 6 feet between phases and 3 feet 6 inches between a conductor and ground. The five 110,000-volt three-pole circuit breakers are electrically operated, and equipped with Westinghouse condenser type bushings. Due to the design of these switches, no concrete barriers or brick work are required, and the switches proper will automatically open by gravity, should accidents occur to their mechanism.

The line outlets consist of corrugated porcelain tubes 40 inches long, supported in a horizontal position by four porcelain posts mounted to the plane of the wall in a treated wooden frame five feet square, and having the intervening space filled with plate glass.

The hoods protecting the outlet bushings from the weather are 8 feet wide and extend three feet below the level of the bushing. On leaving the porcelain the leads drop vertically to a post insulator beneath the hood from the top of which the cable is carried directly to the insulator on the arrester structure. Beneath the wall outlet and this insulator is placed a choke coil constructed of aluminum wire in the shape of a helix with porcelain separators between the adjacent turns.

Lightning protection is secured by two sets of electrolytic lightning arresters, one for each outgoing line, equipped with horn gaps and placed on special steel structures outside the building. The aluminum plates are immersed in boiler iron tanks filled with oil.

Two switchboards are installed in the control room. The main board consists of three 28-inch slate panels, each panel controlling one incoming feeder, the two connected 12,000-volt switches and one transformer bank. Two of the

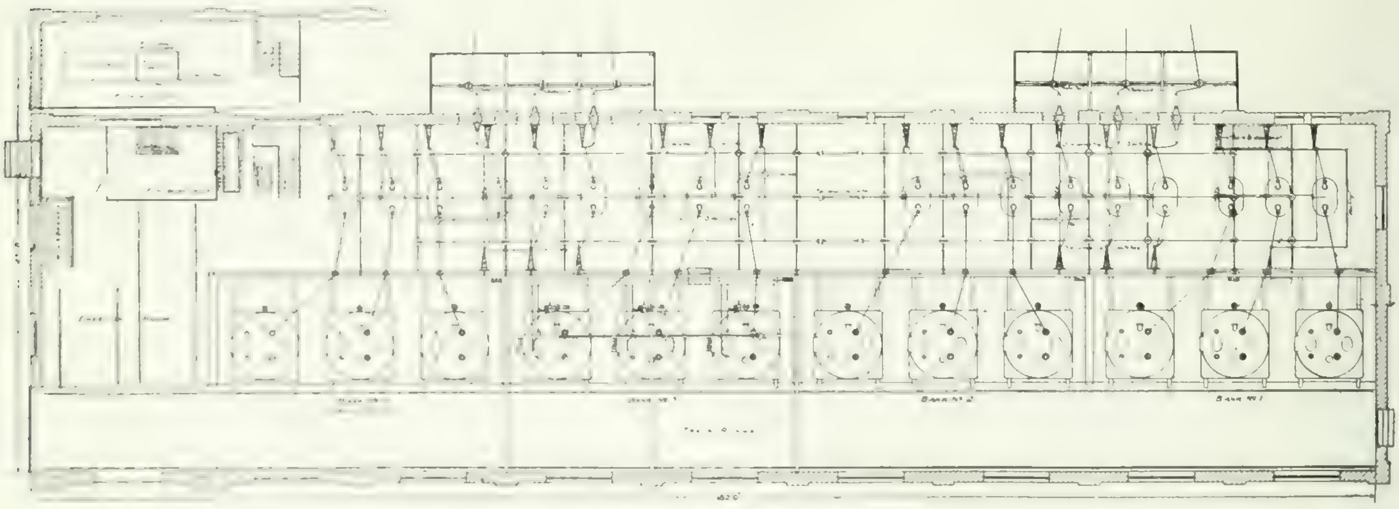

Fig. 23.—Plan View, Niagara Station.

panels, in addition, control the outgoing high-tension lines. Mimic bus connections, and the indicating lamps on the board assist the operator. The recording meters are placed on panels in the rear of the main board. The second switchboard is used only for station service, and controls the main lighting, the motor generator, the battery charging, the crane, the battery, and pump circuits. Illumination is secured by means of incandescent lamps connected to three phases of the 110-volt station circuit. Every third light is wired in such a manner that by means of a no voltage release switch on the service switchboard, these lamps may be quickly thrown over to the battery circuit in case alternating current energy is off.

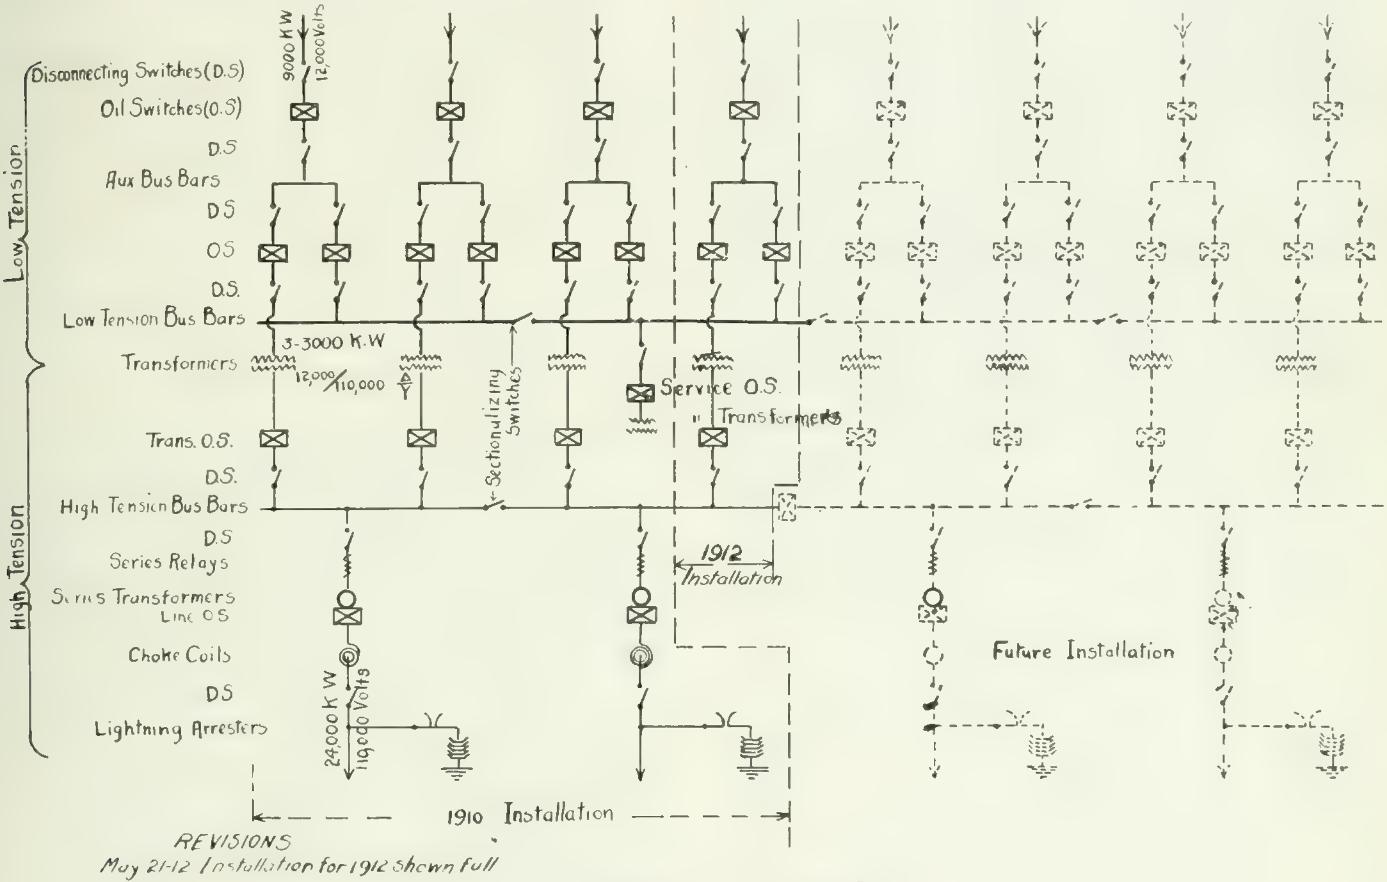

Fig. 24.—Wiring Diagram of Niagara Station.

The water used for cooling the transformers is obtained from wells with auxiliary connections to the city of Niagara Falls and Ontario Power Company's systems. The water, after passing through the transformer coils, is carried to a sprinkling cooling tank, which is an open concrete basin, 6 feet in depth, in two sections, each 30 by 60 feet, with the top just above the ground level. The water is delivered to the basin through sprinklers designed to reduce the temperature of the water, and located some distance above the surface. Duplicate motor-driven pumps are installed for operating this system. The duplicate oil tanks are also installed in the basement, the capacity of each is slightly greater than the oil capacity of one transformer. The transformers are provided at their tops with oil blow-offs piped to a main, running into the "bad" oil tank, which is provided with an oil sealed blow-off and a valve at the bottom for draining purposes. Oil filters and dryers are installed between the tanks, and the oil, after being filtered, is pumped back into the "good" oil tank. An oil pump is also provided for pumping pure treated oil to an "intermediate" oil tank placed on the main floor at an elevation that permits the oil to be drawn into any of the transformers by exhausting the air from the cases by a specially installed motor-driven air compressor and vacuum pump which is pumped to the different transformer cases. This equipment may be operated as a vacuum pump for drawing oil into the case, or as a compressor for pumping in air to assist gravity in emptying it. The high-tension oil switch tanks are connected by pipes to a switch oil tank in the basement, also connected to the oil filter.

All stations in the system are equipped with similar oil and air circulating systems. The water system is varied in the different stations to suit local conditions, but in such case duplicate pumps are provided unless the station is connected to the local mains. The construction room is located near the end of the building, and contains a 45-ton traveling crane, with electric hoist, hand bridge and trolley travels. The control room is situated near the erection room in an enclosed gallery overlooking high-tension switch and erection rooms. From this gallery the operator has an unobstructed view of the erection and high-tension switch rooms. Eventually, the erection and control rooms will be located in the centre of the building, and 344 feet long by 50 feet wide.

The high-tension switch room extends along one side of the building, contains all the high-tension transformer lines, disconnecting switches and high-tension busbars.

◆

A wrecking expedition is now at work over the hulk of the old ship Pewabic which sank in Thunder Bay nearly fifty years ago. The vessel is one hundred and sixty feet below the surface and in order to allow the diver to work at this depth a device known as the iron man is being used. It is known that the Pewabic carried over four hundred tons of copper and it is planned to bring this to the surface, a couple of hundred pounds at a time on days when the lake is calm. The use of the iron man is expected to work a revolution in deep water work. The divers are connected by telephone to the surface.

SOME FALLACIES AND FACTS CONCERNING ENGINEERING WORKS IN GREAT BRITAIN.

By W. A. MARTIN,
Late Assistant General Manager of the Toronto Electric Light Company.

During the past winter I paid a visit of some three months to England looking into the question of the sale of British-made engineering appliances and raw materials in this country, and while there was afforded an opportunity of going over a number of engineering works in the United Kingdom. As a result, my ideas of the methods and general practice adopted in these works have undergone a complete change.

I had always understood, in common, I believe, with the majority of Canadians who have not visited British engineering works, that English methods were old-fashioned and out of date. I pictured to myself old and badly lighted shops crowded with obsolete machinery, a large proportion of which I had anticipated would be standing idle owing to general shortage of work.

I had always been given to understand that the principals of British engineering works were generally very conservative and unapproachable men, and that they were more or less indifferent as to the trade conditions with Canada, and looked upon our market as belonging, for the most part, to our neighbors of the United States.

All these ideas I have found to be entirely fallacious.

At every works visited I received a most hearty welcome from the principals, whom I found to be broad-gauge business-men, showing the keenest interest in the prospects of trade with Canada. The works were, in practically all cases, well laid out and fully equipped with such modern tools and machinery as to secure the maximum output combined with the greatest accuracy, and what surprised me most of all was, that many of the buildings were of comparatively recent construction, thoroughly up-to-date, and in many cases new buildings were being erected to provide for extensions of the plants, owing to the immense amount of work in hand and the constantly increasing orders coming from practically all parts of the world. I saw plant of various kinds in course of construction for South America, South Africa, India, Australia, New Zealand, Japan, China, France, Spain, Italy and the United States and Canada.

New and improved tools were being installed in practically every factory visited, either to replace less efficient tools or otherwise increase the output of the factory. I saw very few tools standing idle, and in many factories day and night [illegible] in order to keep pace with the work in hand.

[illegible]

This inspection of parts is rather a fetish with the Brit- [illegible] some cases. There is no doubt, however, that it is this care [illegible]

[illegible]

[illegible]

manufacturers in the United Kingdom cater, permits of such specializing in a manner that would obviously not be possible in countries where manufacturers cater almost exclusively for home consumption.

Factories operating with from 300 to 600 employees are usually engaged in the manufacture of only one line of machinery, and although the larger works employing many thousands of hands, may specialize in, perhaps, half a dozen different lines, the manufacture of each specialty is confined to a distinct branch or department of the works, under the direct management and control of experts in that particular line of manufacture.

One direct result of this specializing has been that certain manufacturers have been able to establish the highest possible reputation as makers of the particular line of apparatus for which they have become noted, and this reputation is so jealously guarded that the makers' name on an appliance is the best possible guarantee of its high quality.

The name some of these makers have acquired enables them to secure orders for their products even from countries protected by a very high tariff wall.

In several of the works I visited my attention was, for instance, drawn to work in course of construction for shipment to the United States.

Sir W. G. Armstrong Whitworth & Co.

One of the most interesting works it was my good fortune to visit was that of Sir W. G. Armstrong-Whitworth & Co., Limited, of Newcastle and Manchester. This firm employs in its various departments over 20,000 men. Their shops and yards cover a ground area of over 270 acres.

Sir W. G. Armstrong Whitworth & Co.'s name is, perhaps, the best known in connection with their extensive ordnance work and shipbuilding yards, but a very important branch of their manufacture is the hydraulic and electric crane and dock and harbor equipment department. Here are to be seen in course of construction massive hydraulic appliances of a variety of descriptions, including enormous dock gates, swing bridges, cranes of carrying capacities ranging from 30 cwt. up to 250 tons, and hydraulic presses, which for many purposes are now taking the place of steam hammers for every large work. One of these presses in course of construction at the time of my visit, was stated to be of a capacity of 1,000 tons.

Although there are some cases for which Sir W. G. Armstrong Whitworth & Co., recommend and supply electrically operated appliances, as being more suitable than Hydraulic appliances, the latter are, for many reasons, generally preferred for this class of work. While Armstrong & Whitworth make a specialty of traveling cranes for shop and other uses—both electrically and hydraulically operated—they have devoted special attention to the construction of hydraulic cranes for the rapid loading and unloading of vessels. At their Elswick works at Newcastle-on-Tyne, they have an enormous crane erected on the river bank alongside of the building where they carry on the manufacture of ordnance, etc. This crane is capable of handling 150-ton lifts, and is so arranged that is can be swung over the building in question and through openings in the roof; can pick up huge cannon gun mountings and other equipment for the war vessels they build, and lift them bodily on to the vessel which is brought alongside for that purpose.

Whilst fully realizing the advantages of hydraulic power for heavy work such as the above, it struck me that the severe winter conditions in Canada would make it impracticable to use such power here, and I brought this question up. I [illegible] with the statement that Sir W. G. Armstrong

Whitworth & Co. had supplied a number of hydraulic cranes for use in parts of Russia, where the cold is even more severe than in Canada, and that they were operating with entire satisfaction, the danger of freezing being overcome by drawing off the water from the machines when not in use or where this is not practicable by using petroleum or by treating the water with glycerine. I was told that this latter mixture is supplied as part of the equipment in the first place, and that the wastage in operation is so little as to make the cost of future supplies of glycerine negligible.

Messrs. Reyrolle & Co.

Another works visited in the Newcastle district was that of Messrs. Reyrolle & Co., makers of electric switchgear. This business was started in London 26 years ago by Mr. Reyrolle, the present proprietor, assisted by about ten employees. Here, again, we see the effect of specializing in one line of manufacture. By concentrating their attention upon the perfecting of electric switchgear, this firm has been able to establish a reputation which, for that particular line of work, is probably second to no other in the world. They now employ about 500 hands making nothing but electric switchgear, for which they obtain orders from all parts of the world. I was particularly interested to see switches in course of construction for both the Boston and Chicago Edison Companies. Messrs. Reyrolle & Co. have paid particular attention to perfecting a line of switchgear for mining work and sub-station control. This gear appears to be as near fool-proof as it is possible to make it. All the gear is made up of individual units, which are absolutely standardized, and can, therefore, be replaced by, or interchanged with, other units of a similar size.

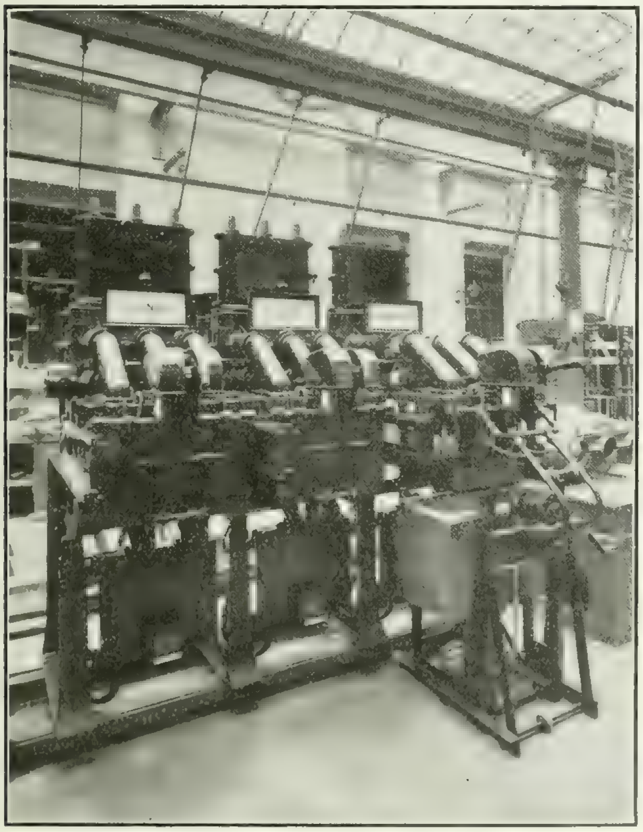

Fig. 1.—Front View of Switch Manufactured by Reyrolle & Co., for Shipment to the United States.

Another switchgear shown on the accompanying photographs was awaiting despatch to another large American power company. The first photograph shows the front view of this switchgear with the switch controlling the transformer circuit isolated and the oil tank lowered on a truck to be supplied for this purpose. The second photograph shows the back view of the same gear.

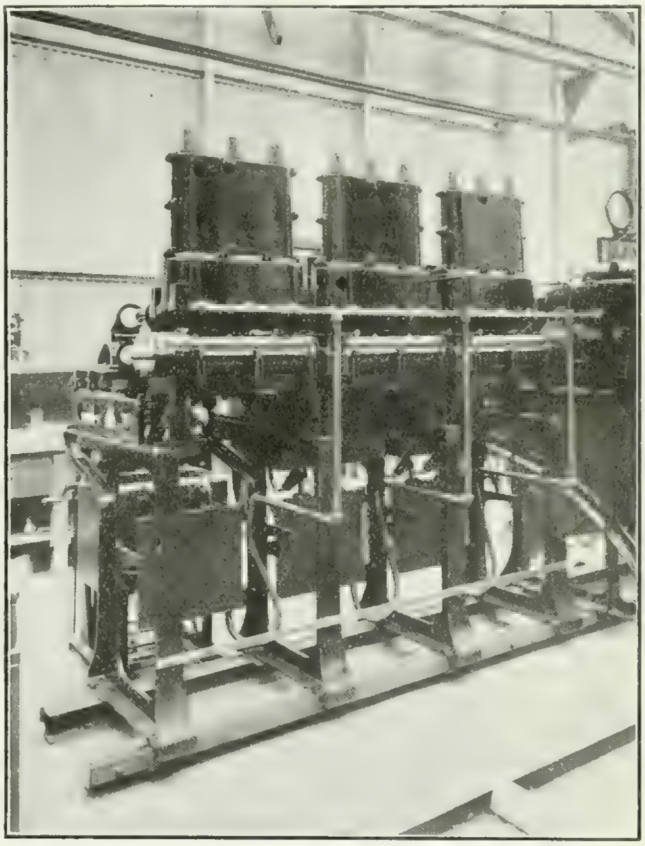

Fig. 2.—Rear View of Switch Gear Manufactured by Reyrolle & Co., for Shipment to the United States.

I was informed that this firm had installed in the Northumberland and Durham district alone about 750 similar panels. These were included in 120 sub-stations in that district and some idea as to the reliability of this gear will be gathered from the fact that the generating plant capacity of the power stations amounts to over 100,000 k.w.

Plans were in hand for power station switch panels to control generator circuits of sizes up to 12,000 k.v.a., and I have heard since that they are making the power and substation gear for Sheffield corporation power station at Neepsend, where 40,000 k.w. generating plant is to be installed.

Messrs. Cammel, Laird & Co.

While in Sheffield I was afforded an opportunity of going through the Cyclop Works of Messrs. Cammel, Laird & Co.

Sheffield steel is synonymous with best quality steel the world over, and of all the many steel workers in that city the name of "Cammel-Laird" ranks at the top as specialists in the manufacture of high-grade steel.

The fact that they employ in their combined works at Sheffield and Birkenhead and Penistone over 16,000 workpeople, is, in itself, some indication of the enormous output from these works. The total area covered by the combined works is over 160 acres. The management are justly proud of the immense business that has been built up and is now under their charge, and I was furnished with very full information as to the history of the company and its progress since its first organization in 1837.

The original firm of Johnson Cammel & Co. has twice been changed, in 1852 having been changed to Charles Cammel & Co., and in 1903, when, in order to share in the advantage of being in a position to build a battleship complete, the well-known shipbuilding business of Laird Brothers, Limited, Birkenhead, was acquired, the style of the firm was again changed to that of Cammel-Laird, Limited. In furtherance of this policy large ordnance works were started at Coventry for the manufacture of armour and guns.

The Cyclops Works have been visited from time to time by many members of the Royal family (including King George V. and Queen Mary when Duke and Duchess of York) and the reigning houses on the continent, as well as by distinguished statesmen and noted military, literary and scientific people from all parts of the world, but it is a unique record to be able to crown the list by the visit of her late Majesty Queen Victoria, who, on the 21st May, 1897, in the 60th year of her glorious reign, witnessed at her own [illegible]. The [illegible] of an armour plate destined for H.M.S. "Ocean.' The event is especially interesting [illegible] and the only [illegible] undertaken by her late Majesty during the [illegible] of her reign.

The [illegible] of the firm include armour plates, guns, projectiles; steel tyres, axles, springs and buffers for locomotives, carriages and wagons; locomotive crank axles, steel rails, fish plate, sole plates, billets, blooms and bars by the "acid" process; steel castings and steel forgings of all kinds for shipbuilders, engineers and mining machinery; high-speed tool steel; nickel steel for motor cars and wagons, etc.; best crucible cast steel for engineers' and blacksmiths' tools, mining drills, etc.; files, hammers, picks, [illegible], etc.

[illegible] the company's various works, but I may say that the annual [illegible]

The [illegible]

[illegible] previous to rolling.

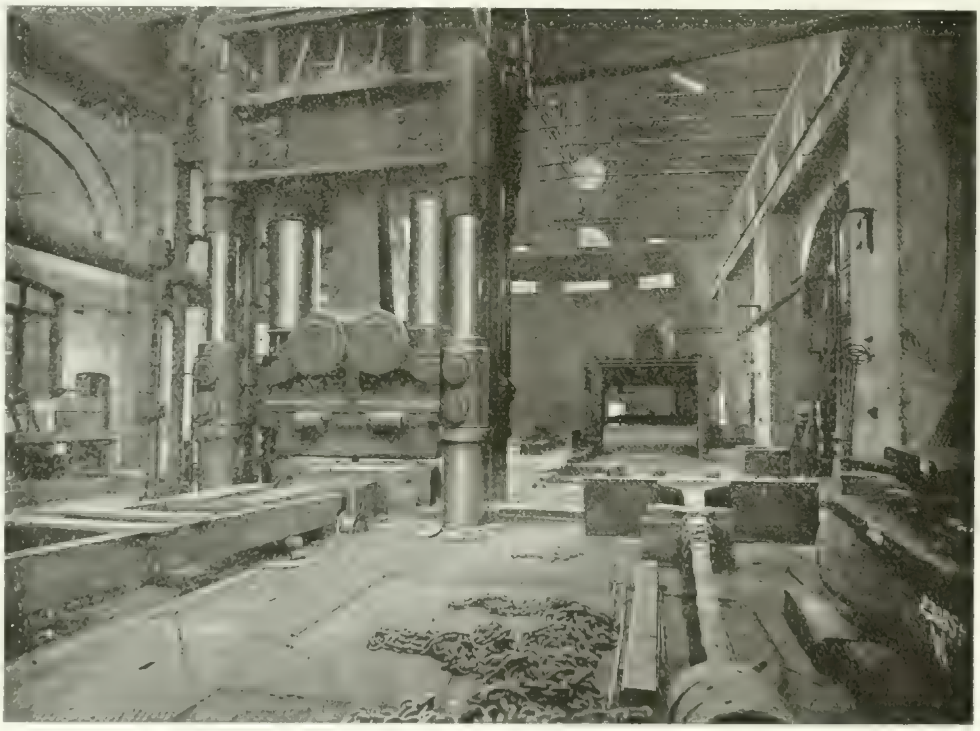

Fig. 3.—View of the Armour and Press Shop of Cammel, Laird & Company, Limited, Sheffield.

The armour mill in the background, one of the largest in existence, has rolls 14 feet long by 4 feet diameter, and is driven by three cylinder h.p. engines, of 12,000 horsepower.

The process of steel making and treating in all its branches is most fascinating. From the large gas-fired furnaces, where it is seen boiling and bubbling like water until it is run off into ingots, and then whilst still red hot carried by goliath cranes to one of the large hydraulic presses, there to be squeezed into a forged block from which later a large gun is to be turned. Or it may be that its fate is to be rolled into railway tyres or carriage springs, or possibly to be hammered into rods of different sections for high speed tool steel, to be eventually made into tools which will retain their cutting edge when red hot. Or again, it may be forged into armour plate 12 inches or more in thickness for the protection of battle ships. The ingredients of the mixture are in some cases varied according to the purpose for which the steel is to be used, and the mixture has to be of different characteristics in different sections of the mass. For instance, in the armour plates referred to the face to a depth of a few inches must be hard and brittle to resist penetration, whereas the back of the plate must be tough and tenacious to avoid risk of fracture.

Messrs. Cammel Laird have established a branch in British Columbia, through which they are doing a considerable business in their special tool steel for mining purposes, including rock drills, stamps and dies, etc.

Messrs. Ashmore, Benson, Pease & Co., Limited, and Messrs. The Power Gas Corporation, Limited.

Messrs. Ashmore, Benson and Pease, of Stockton-on-Tees, specialize in the manufacture of structural iron work, including large gas holders, large rivetted pipes for hydroelectric plants, etc. At the time of my visit this firm were just completing a contract for 450 tons of pipes twelve feet in diameter, to be shipped to British Columbia for the hydroelectric plant of the Ocean Falls Company. They have also recently executed a contract for the supply and erection of a large gas holder for the city of Vancouver, having a capacity of six million cubic feet.

Messrs. Ashmore, Benson and Pease also manufacture [illegible] gas producers, gas cleaning plants, Mond sulphate of ammonia recovery plants, etc., supplied by the Power-Gas

Corporation. Amongst the many interesting installations recently carried out by this latter firm is a plant for the recovery of sulphate of ammonia from peat. This installation is stated to be an entire commercial success. In the process of recovering this very valuable fertilizer from the peat, large quantities of gas are given off, which may be used for generating power in large gas engines. In a similar installation in Germany the waste gas is already being successfully utilized in this way.

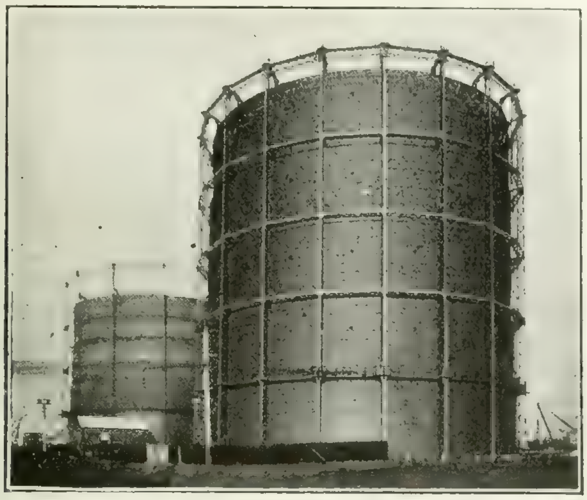

Fig. 4.—Large Gas Holder Manufactured by Ashmore, Benson and Pease for use in the City of Vancouver, B.C.

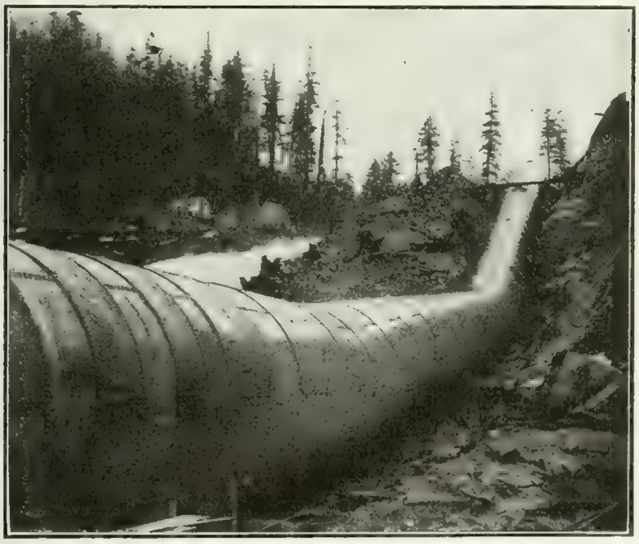

Fig. 5.—A Section of 12-ft. Pipe Line Manufactured by Ashmore, Benson and Pease for the Ocean Falls Power Company, British Columbia.

(To be continued.)

CANADIAN BOUNTY PAYMENTS.

The total amount paid in bounties by the Canadian Government for the year ending March 31 last, was only $538,529, compared with $1,591,663 for the preceding year. The bounties paid were as follows: Wire rods, $160,750; crude petroleum, $141,935; lead, $179,288; manila fibre, used in the manufacture of binder twine, $50,556. Since 1896, when the bounty system was introduced, the total payments have been a little over $21,000,000, of which $7,000,000 went for pig-iron, over $4,000,000 for puddled iron bars, and $6,000,000 in steel bounties.

TURBINE-DRIVEN CENTRIFUGAL PUMPS FOR WATERWORKS SERVICE.*

By W. O. Beyer.

It is only recently that centrifugal pumps have received the serious consideration of waterworks engineers, although their economy and efficiency have long since been demonstrated for supplying water in large quantities to industrial plants. It is our purpose here to show that the combined fixed charges and operating costs of the rotatory unit compare favorably with those of the high-duty vertical triple-expansion unit or other type, where the price of coal is not excessive.

The high duty shown by reciprocating engines in waterworks service, involving the pumping of large quantities of water against a constant head, without any great variation in rate, has long and justly been regarded as a supreme achievement. Due to the direct connection of the pump and engine cylinders and to the high efficiency realized in the unit when the proper attention is paid to its valves and packings, the triple-expansion reciprocating pumping engine has been able to develop duties that are unapproachable by rotatory units consisting of turbines and centrifugal pumps. However, a careful comparison of the total costs of pumping will show that the balance may be entirely reversed when fuel costs do not exceed a certain price per ton. That is, the high first cost of the reciprocating unit, together with the cost of the foundation required, introduce annual charges for interest, upkeep and depreciation, which more than offset the lower duty of the turbine unit.

Of the several types of pumping engines, the following are chiefly used for waterworks service: The low-duty compound condensing engines, costing, with foundations, piping and appurtenances, about $2,300 per million gallons capacity per 24 hours; low-duty triple-expansion condensing horizontal engines, costing about $2,800 per million gallons capacity; cross-compound condensing horizontal fly-wheel engines, costing about $3,300 per million gallons capacity, and high-duty triple expansion vertical condensing engines, costing about $4,800 per million gallons capacity. The figures given are from a paper presented before the American Society of Civil Engineers, May 17, 1911, by the late Charles A. Hague. Since this paper selected the high-duty triple-expansion vertical engine as the only one to be considered in most cases, it is with this type of engine that we shall make our comparison.

The prices for pumping units given below are, to the best of our knowledge, accurate and include condensers, piping and foundations complete.

No account has been taken of the greater volume required in the buildings for reciprocating units, as a unit volume cost must be assumed which would agree with only one architectural design; similarly, no account has been taken of the greater volume required for the larger boiler installation of the turbine units, for the majority of existing plants usually have their building proportions determined, and a saving could not be made in either room without special complications of no account in this discussion. However, the difference in cost of foundations has been taken into account, because this is an addition in existing buildings and can be computed easily.

---

* Paper read before the American Waterworks Association.

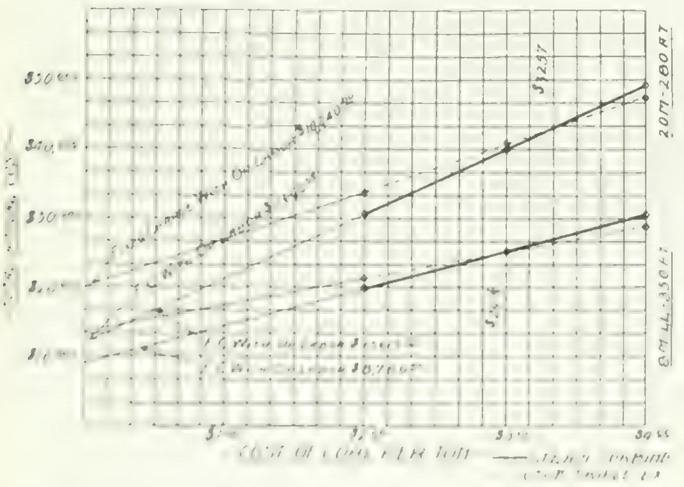
In a new station the turbine should be credited with any saving in floor space, buildings, etc., which it may effect, as compared with the reciprocating engine, and the reciprocating engine credited with the saving effected in the boiler rooms.

In a comparison of this kind certain assumptions must necessarily be made. We have tried to eliminate as far as possible arbitrary assumptions, and all figures of first cost of apparatus have been taken from, or estimated from, recent bids on the two types of machinery under consideration. The first cost per boiler horse-power we have taken to be $30, complete with piping, chimney, stokers, etc. (The use of a lower figure would favor the turbine-driven pump as compared with the high-duty engine, but we believe, with everything taken into consideration, this will prove to be an average figure.) We have assumed the following annual charges against pumping machinery:

Interest	5
Depreciation	3
Repairs and supplies	2%
Total	10

We have also assumed the following annual charges against the boiler equipment.

Interest	5
Depreciation	5
Repairs and supplies	5%
Labor on maintenance	2%
Total	17



Comparisons of Operation Cost of Steam Turbine and Triple Expansion Engines, Small Plants.

[illegible]

[illegible] count, we believe the assumption a fair one. Viewed in the light of possible future development, it would seem that a longer life should be accorded to the turbine-driven unit than to the crank and flywheel unit, as a very thorough canvass of the whole field of pumping equipment does not bring to light any mechanical apparatus which is being developed to compete with the turbine-driven machinery to the same extent as the turbine-driven machinery is being developed to compete with the crank and flywheel machinery.

It further appears that the steam turbine has reached a stage of development, such that improvements will appear only as refinements of type; and steam economies can only possibly be reduced sufficiently to render obsolete the present good designs by better theoretical design and by better steam conditions. The use of high steam pressures and superheat may be expected to gradually obtain further favor in this country as in European practice, where 250 degrees Fahr. superheat and 200 pounds steam pressure are not unusual. This, however, entails practically no change in turbines as constructed for present steam conditions.

Fuel costs are based on a boiler efficiency of 65 per cent., heat content of 13,000 B.t.u. per pound of coal and 24-hour per day operation.

The duties given are on a basis of 150 pounds steam pressure, with no superheat.

Three examples are taken, based on coal at $2, $3 and $4 per ton. Where coal can be obtained cheaper than $2 per ton, the advantages of the turbine-driven pump are more clearly marked.

It will be noted that the point at which the total annual costs are equal for the eight-million-gallon crank and flywheel vertical unit and the eight-million-gallon turbine centrifugal unit is when coal costs $2.91 per ton. Also for the twenty-million-gallon vertical crank and flywheel unit and the twenty-million-gallon turbine centrifugal unit, the total annual costs will be equal when coal costs $3.25 per ton. Above these points the reciprocating unit has the advantage, and below these points the rotatory unit has the advantage, on the basis of these calculations.

Tabulation "A."

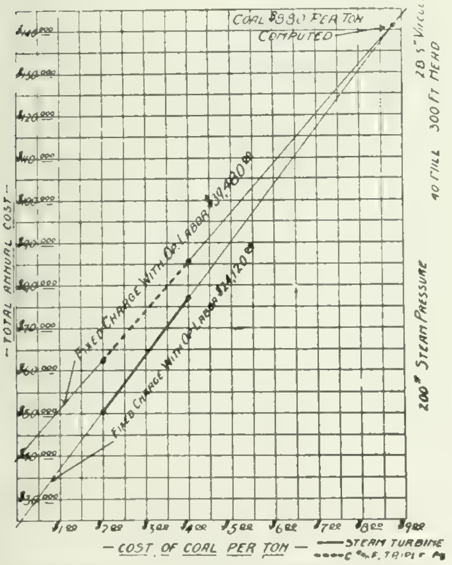
Total annual cost, $2 coal	33,510	30,320
Total annual cost, $3 coal	40,275	39,635
Total annual cost, $4 coal	47,080	48,950

We believe it can be assumed safely that the development of pumping machinery in the future will be along somewhat the same lines as the development of power-producing machinery. At the present time one of the most noticeable features in the development of power machinery is the increasing favor with which larger units are being adopted. In large central station work five years ago, the ordinary size of unit was from 10,000 to 15,000 k.w. Now, not only in European practice, but also in American practice, 25,000 k.w. units are being installed in the larger stations. There are two reasons for this development, the first being the continual endeavor to obtain better economy, not only in actual steam consumption, but in capital charges, including first cost, buildings, real estate, etc. The second reason for the development along this line comes from the fact that engineers of to-day seem to have more initiative than formerly, and where before the development of a 15,000 k.w. turbine would have seemed an impossible task, now the installation of 25,000 k.w. turbines is becoming a matter of course.



Comparisons of Cost of Steam Turbine and Triple Expansion Engines, Large Plants.

We have assumed that there will be progress along this line in waterworks pumping machinery, and that installations of very large units will be made in the future. We have evolved a comparison between two units of the types under consideration, each having a capacity of 40,000,000 gallons per 24 hours, against a total head of 300 feet. This comparison is based on utilizing the greatest range of steam temperature which the best modern practice has established as commercially practicable, and which at the same time is not too intensely theoretical. We refer here to European practice, in which steam pressures of 200 pounds, 275 degrees superheat and 28.5 inches vacuum are successfully and commercially utilized. Especially important in this connection is the item of high vacuum, since in the case of waterworks large quantities of water are always available for condensing purposes.

Extremely large capacities and high heads present no difficulties nor disproportionate costs in the construction of steam turbine-driven centrifugal pumping units, since it is an inherent characteristic of the centrifugal pump that the larger the capacity, the greater the efficiency for a given head.

There is practically no development necessary on the turbine to take advantage of these conditions, as the turbine of almost exactly the same characteristics that would be necessary for this installation is now in successful operation in hundreds of power-producing plants to-day. We have had to assume no steam consumption, as this is a matter of test, and practically have had to assume no pump efficiencies, as we have taken the minimum which we know can be obtained on this size pump.

Further, the turbine is well adapted to take advantage of the improvement in steam conditions as mentioned above, and reciprocating engines can also be designed as to take advantage of the initial and terminal conditions favoring high economy.

The results of this comparison are shown in Table "C." It is apparent from these tables that the point at which the two curves of overall economy of the two units cross is at a cost of approximately $8.80 per ton for coal.

It would appear, therefore, that the field of these large capacities at high heads for ordinary coal costs belongs to the turbine-driven centrifugal pump exclusively.

Tabulation "C."

40,000,000 gallons per day, 300-ft. head, 2120 w.h.p., 200 lbs. steam pressure. 275 deg. F. superheat. 28.5 in. vacuum.

Item	Vertical C. & F. W. Triple Expansion, 223,000,000 Duty, 3 350 h. p. Boilers	Steam Turbine Centrifugal, 193,000,000 Duty 3 400 h. p. Boilers.
Cost, pump	$210,000	$55,000
Interest, depreciation, etc., 10%	21,000	5,500
Cost, boilers	31,500	36,000
Interest, depreciation, etc., 17%	5,360	6,100
Labor, three shifts—		
Engines	7,200	7,200
Boilers	5,320	5,320
Total int., depreciation, etc., and labor	39,480	24,120
Fuel cost, $2 coal	23,265	26,800
Fuel cost, $3 coal	34,897	40,200
Fuel cost, $4 coal	46,330	53,600
Total annual cost, $2 coal	62,475	50,920
Total annual cost, $3 coal	74,377	64,320
Total annual cost, $4 coal	85,810	77,720

In conclusion, if the above data are correct—and it has been our sincere endeavor to present only such figures as are fair for both types of machines—it would seem that the steam turbine centrifugal pumping unit must be conceded a place of primary importance in the field of waterworks engineering.

RESULT OF FILTRATION AT ALBANY.

The filtration plant at Albany, N.Y., which receives its supply from the Hudson River and comprises a sedimentation basin, 16 roughing filters and 8 slow sand filters, each having an area of 0.7 acres, purified during the year ending September 30, 1911, an average daily quantity of 21,506,490 gal. at a cost of $5.32 per million gallons, including a charge of $2.64 per million gallons for pumping. The latest annual report of Mr. H. J. Deutschbein, superintendent of the Bureau of Water, to Mr. Wallace Greenlach, commissioner of Public Works, contains the following data on the operating results during the year.

The raw water was remarkably uniform in its character during the year. The turbidity average 22 parts per million, the color 35 parts and the bacteria 37,166 per cubic centimeter. There were no especially heavy freshets: each reaching its maximum height gradually and subsiding slowly. The sharpest flood stage occurred from December 31 to January 21, when the water rose to El. 105 in 24 hours. The largest freshet extended from February 27 to May 23, the highest stage being reached on April 17 at El. 106.8. The turbidity was highest at this time, being 400 parts per million. Table 1 shows the efficiency of the system under extreme conditions:

Table 1.—Operating Results During Largest Freshet, March 29.

	Suspended matter.	Turbidity.	Turbidity coefficient.	Suspended matter efficiency, per cent.	Turbidity efficiency, per cent.
River ..	[illegible]	400	0.43	....	....
Basin ..	[illegible]	320	0.19	62.9	20.0
Primary Eff. .	[illegible]	80	0.24	69.8	75.0
Secondary Eff.	0	0	...	100.0	100.0

From table 1, it is seen that most of the matter in suspension was of a coarse nature, nearly 70 per cent. being taken out by the basin. The primary filters easily removed the remainder. The plant as a whole experienced no difficulty in handling this flood.

Owing to the uniform conditions the water was of a weaker nature than of past years. The average bacterial content per cubic centimeter being 37,000 against 44,000 of last year. The organic matter likewise was below normal. During the latter part of July and the early part of August, a heavy growth of sponge developed, which seeded up the basin and primary filters to such an extent that the spores were carried over onto the secondary filters and materially lessened their lengths of runs. The life cycle of this organism was short, however, and did not necessitate any remedial measures.

The basin was out of commission from November 1 [illegible] Since the last cleaning 16,514,600,000 gal. of water passed through the basin. This amount of water caused the deposition of 1,770 tons of silt, or approximately 0.11 ton per million gallons. Most of this silt subsided immediately upon entrance, the remainder settling [illegible]

[illegible] experienced from aquatic organisms.

[illegible]

Primary Filters.—[illegible] cent., it was necessary to employ two supplemental washes during the year. At these times the entire sand layer down to the gravel was ejected and replaced by means of the Nichols separator. Before these beds were washed in this manner, the average initial loss of head at a 70,000,000-gallon rate was 2 feet. After washing, the initial loss of head was reduced to 0.8 feet.

Primary filter No. 9 is supplied with a uniform quartz sand whose effective size is 0.65 mm. All the other beds have a uniform sand of effective size of 0.45 mm. Table shows a comparison between primary No. 9, with a coarse sand, and primary No. 12, with a fine sand, before and after the supplemental wash:

Table 2.—Washing Coarse and Fine Sands.

Primary Filter No. 12 (Fine Sand).

	Before Wash.			After Wash.		
Section.	Turb.	Org-N.	Ox-con.	Turb.	Org-N.	Ox-con.
0-10 in.	4000	2.04	43.8	1200	0.97	25.5
10-30 in.	3500	2.44	35.6	1500	1.45	26.4

Primary Filter No. 9 (Coarse Sand).

	Before Wash.			After Wash.		
Section.	Turb.	Org-N.	Ox-con.	Turb.	Org-N.	Ox-con.
0-10 in.	3200	1.45	40.0	950	0.13	11.6
10-30 in.	2000	1.20	21.6	1000	0.18	12.5

Note.—Organic nitrogen and oxygen consumed determinations are expressed in parts per 10,000 dry sand.

From the above table it is clearly shown that the normal upward flow wash is much more effective with a coarse sand, and that the efficiency of the supplemental ejection is far greater.

10 in.-20 in. after wash	[illegible]	[illegible]	[illegible]
20 in.-30 in. after wash	 950	[illegible]	[illegible]

Secondary Filters.—When the entire sand in all the secondary filters was washed and replaced down to the gravel, by ejection in the fall of 1909, the sand was of the following degree of cleanliness: Turbidity, 800; average of organic nitrogen, 0.25 part per 10,000 gm. sand and oxygen consumed equivalent of 3.5 parts per 10,000 gm. dry sand. One month following the cleaning of this sand the top 2 in. of the beds were in the following condition: Turbidity, 1,300; organic nitrogen, 1.40; oxygen consumed, 11.3. Five inches below the surface was in the following condition: Turbidity, 900; organic nitrogen, 0.38; oxygen consumed, 7.2. It is thus seen that there is a decided penetration of silt and organic matter into the top 4 in. of the bed, the degree of penetration depending upon the conditions in the river. As a consequence of this penetration the bed becomes hard and compact in time, so that remedial measures must be adopted.

In the spring of 1911 so much sand had been removed from the tops of the beds in the consecutive scrapings, and the top 10 in. had become so silted up and compacted, that it was decided to eject and replace. Five secondary filters had 10 in. of their top sand washed and replaced, and 10 in. of fresh sand added. Table 3 shows the condition of the sand before and after washing and replacing.

The total quantity of water filtered during the year was 7,849,869,000 gallons, making an average of 21,506,490 gallons day. The average rate of filtration was 4,018,000 gallons per acre per day for the secondary and 80,500,000 gallons per acre per day for the primary filters. The average quantity of water filtered per unit of 0.7 acre, between scrapings, was 85,338,000 gallons, or 121,911,000 gallons per acre. The maximum rate at which any secondary filter was operated was 6,000,000 gallons.

All filters have been operated at a 5,500,000-gallon rate when necessary, and have given good results. Cleanings were made on the eight filters 93 times, and two units were raked and put in service. The average scrapings for the eight units was 11.66 times each. During the past year 316,386 sq. yd. of filter surface was scraped in 2,663 man-hours, making an average of 2,865 man-hours per scraping of each filter or each 3,402 sq. yd.

During the year 5,100 cu. yd. of sand have been washed and replaced in 2,897 man-hours. There were 2,666 cu. yds. replaced from the storage pile in 1,666 man-hours. During the year 5,572 cu. yds. of sand have been ejected to the rear of the filters in 4,126 man-hours, an average of 48.54 per cleaning, and an average of 65.5 cu. yds. per cleaning; there were 85 cleanings ejected. The sand to a depth of 10 in. has been washed and replaced, and sand from the rear filters replaced in filters Nos. 1, 6, 7, and 8, leaving them with a uniform depth of 3 ft.

All pre-filters have had the sand removed, washed and replaced twice during the year, as it was found necessary to do so. The sedimentation basin has been thoroughly cleaned and 1,770 tons of silt removed. The hypochlorite machine has been in operation all year and has proved satisfactory in the results obtained.

During the year there was cut and housed 125 tons of ice, the full capacity of the ice house.

The average removal of the preliminary filters was 81 per cent. of the bacteria, incubated on gelatin at 68° Fahr., 74 per cent. of the acid colonies incubated on litmus lactose bile agar, 72 per cent. of the turbidity and 10 per cent. of the color. The efficiency of the filters was lowest during the winter months; the average removal of the bacteria incubated on gelatin from Nov. 1 to April 1 was 70 per cent., and for the remainder of the year 88.3 per cent. Twice during the year the entire sand layers in these filters was ejected, washed and replaced.

The average effective size of the sand in the preliminary filters is 0.45 mm. In December, 1909, a sand of an effective size of 0.65 mm. was placed in Filter No. 9. This sand has proven more advantageous, giving as great efficiency as the finer sand, and materially lengthening the runs and reducing the required wash-water. The average length of run for the past year of preliminary Filter No. 9 was 55 hours, the average rate 79,300,000 gallons per acre per day, and the wash-water percentage of the gross yield 2.6. It is proposed to equip one preliminary filter with sand of an effective size of 1.2 mm., with a view of determining that size of sand which will operate most economically and maintain the standard of efficiency desired.

Commencing on Nov. 19, 1910, and continuing throughout the year, hypochlorite of lime has been applied to the effluent of the slow sand filters. The average application has been 0.35 part per million of available chlorine. This treatment was used as a safety factor during the cold months, and was continued during the summer, in order to determine whether by such treatment the number of cases of typhoid fever and diarrhoeal diseases could be diminished. Owing to the large number of factors entering into the causation of these diseases, it is impossible to determine from one season's record whether such effect has been produced. Before a definite conclusion can be reached, the application of bleach will have to be continued for a period of two or three years.

With the help of sterilization the average removal of bacteria, gelatin count, between the influent of the slow sand filters and the pure well has been 99 per cent.

The average number of bacteria sent to the city for the year was 39 per cubic centimeter, with a maximum average for November, when hypochlorite was used but half the month, of 183 per cubic centimeter, and a minimum average in the month of August of 4 per cubic centimeter.

The cost per million gallons of delivering filtered water to the consumers of Albany is subdivided among the following items: Pumping station expenses, $2.64; sedimentation basin, 3 cents; preliminary filters, 53 cents; slow sand filters, $1.04; laboratory, 53 cents; hypochlorite plant, 26 cents; superintendence, 29 cents; total, $5.32 per million gallons of water filtered.

ACCIDENTS IN BUILDING WITH REINFORCED CONCRETE.*

By Dr. F. von Emperger, Vienna.

(Translated by C. Salter.)

Experiments in which accidents in the course of building are brought about by design are known to be capable of affording valuable information on the properties of materials; and thus an accident during building also forms a material test, carried to the point of rupture and furnishing particulars of a defective property of the material. It is naturally to the general interest that these tests should be confined to the laboratory and we believe therefore that these experiments and the increased knowledge gained thereby on the building materials and their coaction form the means whereby accidents in practice may be prevented. In order, however, to ascertain what are the points on which our knowledge is capable of improvement, and where experimental investigation should begin in order to attack the problem effectually, we must endeavor to trace the main origin of these building accidents and find in what their causes consist. The same dual task had to be faced in drawing up the report on building accidents, presented to the Brussels Congress in 1904. The inadequacy of private means for an exhaustive representation was expatiated upon in that report, and the desire was expressed that a clearer insight into the circumstances of the case might be afforded by the aid of unimpugnable official statistics.

---

* Paper delivered to International Association for Testing Materials.

This endeavor, the primary aim of which is the prevention of accidents, has, in the meantime, been able to record an important success, inasmuch as two countries have given effect to the aforesaid wish of the Congress by introducing a system of official reports, thereby creating an unimpeachable basis for further work of the kind. This was affected in a particularly thorough manner in Germany by an ordinance issued by the Minister of Public Works on 18 September, 1911, which, at the outset, was applicable only to Prussia (see "Beton und Eisen," 1911 p. 361).

This ordinance not only prescribed the procedure to be adopted in all kinds of building accidents (and therefore including also such accidents as, not being attended with any injury to life or limb, were not previously subjected to any jurisdiction), but also ensured competent judgment, by providing a list of experts, whereas the pre-existing reports on building accidents were not only very imperfect, but had also been drawn up, as a rule, by persons more or less unqualified for the work.

A similar, though less detailed ordinance was issued by the Austrian Ministry of Public Works at a somewhat earlier date, viz., on May 8th, 1911, (see "Beton und Eisen," 1911, p. 449). These two important ordinances fulfilled a principal wish expressed in the report of the Brussels Congress in 1906, in this connection, and at the same time created an influential example. At all events they have restricted the system of private reports to the other countries exclusively.

Since the date of the last report, only a few accidents, of little importance, have occurred to excite general attention. In view of the circumstance that these have all been reported in due course in the columns of "Beton und Eisen," the author considers it unnecessary to recapitulate them here, more especially since the published reports lay no claim to completeness, and in many instances are derived from sources that are not always reliable.

One of the chief causes of such accidents has always resided in imperfect knowledge of the material at the same of removing the false work of the concrete, since, in view of the divergent influences to which the material is exposed in building operations, the quality of the material can only be imperfectly judged in the laboratory; or also because, in the absence of any connection between the laboratory and the building site, the material has actually escaped any checking. It has happened, for instance, that the false work has been taken down from concrete which had been spoiled by frost or checked in its development, although the regulations laid down for ordinary average conditions have been strictly complied with, and that the premature dismantling of the false work had [illegible]. Moreover, it has [illegible]

[illegible] the most [illegible] perhaps, at [illegible] builders do not always possess the warning consciousness of danger at the time when the latter is most imminent. For such contingencies, the present writer has found a trustworthy and proved auxiliary* in the form of check — or test beams, which enable one to ascertain, in a simple and reliable manner and on the spot, whether the concrete of a structure is quite ready for the falsework to be taken down, or whether that operation should be delayed, The use of this auxiliary is strongly recommended when building operations are being carried on under unusual conditions, especially in autumn and winter; also in excessively hot weather and when unknown material is being used; and a warning must be uttered against the assumption, so frequently expressed, that an experienced concrete layer can judge concrete by touch. For instance, I have, on several occasions on which specimens of sand and gravel have been rejected, or declared, from their appearance, as bad, by experienced men in the trade, obtained fundamentally different results by means of the test beam. How much less is it possible to determine the influence of cold on the concrete from its external appearance only. For the purpose of affording a thorough check on concrete, I have applied and tested this method (for a description of which, see "Beton und Eisen," 1903) during several building operations in Vienna in 1910; see more especially, Kromus: "Die Betonkontrolle beim Neubau des k. k. Kriegsministeriums in Wien" ("Benton und Eisen," 1911-12) and also an exhaustive description by G. Neumann: "Eine Güterprobe für Beton, System Dr. F. von Emperger," ("Forscherheft" XLI.).

Taking all these circumstances into consideration, the further continuance of the system of making private reports does not seem advisable; and it is recommended that the German and Austrian official representatives should be approached, in order that a report from official sources may be available for the next Congress. The wish might also be expressed that the other States would follow the example, and by means of these facts, afford a comprehensive review of the measures to be adopted for the prevention of building accidents. The matter would become more complicated and important by the inclusion of the Latin countries, such as France, in which there is no stringent building-police supervision, at least of the kind customary in the Germanic countries. It would furnish an opportunity for comparing which of the methods gives the best results, or in which respect they have an improving influence on the contractor, if the statistics were compiled in an approximately uniform manner. The question at issue is whether a high condition of independence and the consequent feeling of responsibility are able to replace the present extensive but always insufficient supervision, or not. The matter of uniformity of the reports demands an international pronouncement, which, however, is only possible on the occasion of our congresses; and it would be desirable if this could be brought about by the time of the next congress.

As one of the most important measures in connection with the widening of our knowledge on the matter in question, the fostering and extension of experiments in building-mechanics in general and in their simplest, and therefore so important form, namely, the test beam, are warmly recommended to all interested in the matter. It would also, in the first place, be desirable that reports on the use of the test beam in practice should be presented to the next congress.

SOME NOTES ON BAND CONVEYORS.

By F. Tissington.

(FOURTH ARTICLE.)

One of the most recent developments in the details of these conveyors consists of a special type of carrier, or roller sets. The idea consists in making each individual roller complete in itself with supports, spindle and bearings, and these are then arranged in twos, threes, fours, etc., to make up a complete carrier for any width of band.

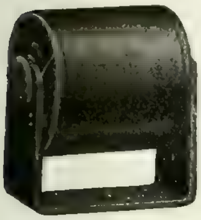

Fig. 18.

Fig. 21 shows a section of a conveyor as made by the Jeffrey Manufacturing Company. This indicates the general appearance of the rollers, and it will be noticed that the three rollers forming the troughing set are each supported in their own bearings.

Fig. 22 is of a similar character, but includes a set of guide rollers such as were referred to in a previous article. This figure is also by the above firm.

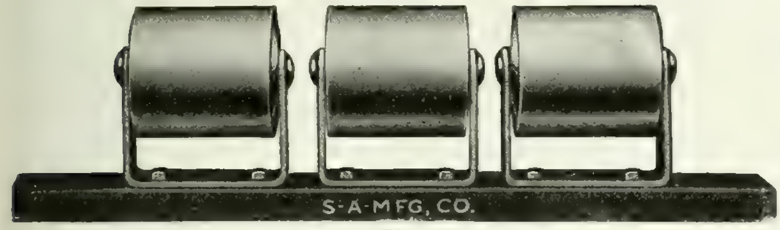

Fig. 19.

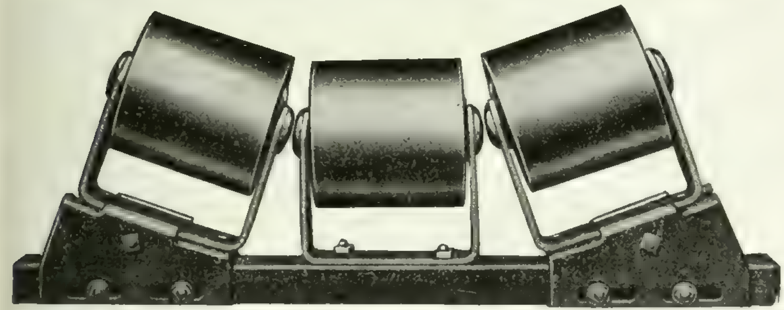

Fig. 20.

Figs. 18, 19 and 20 show carriers as made by the Stephens-Adamson Manufacturing Company.

The first illustration depicts one of their new unit sections which are arranged to suit both the carrying and return sides of the band, and may be with equal facility used for either flat or troughed bands without any alteration in the unit of any kind. The manner in which this is accomplished is seen in the last two figures, viz., 19 and 20.

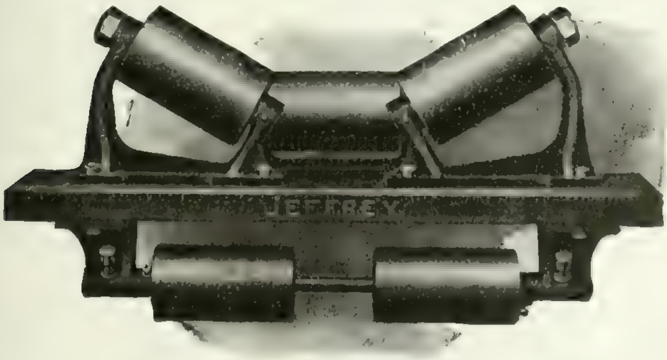

Fig. 21.

If a wider belt is required it is only necessary to add more units to make up for the increased width.

The advantages to be gained with the use of this style of carrier are fairly obvious.

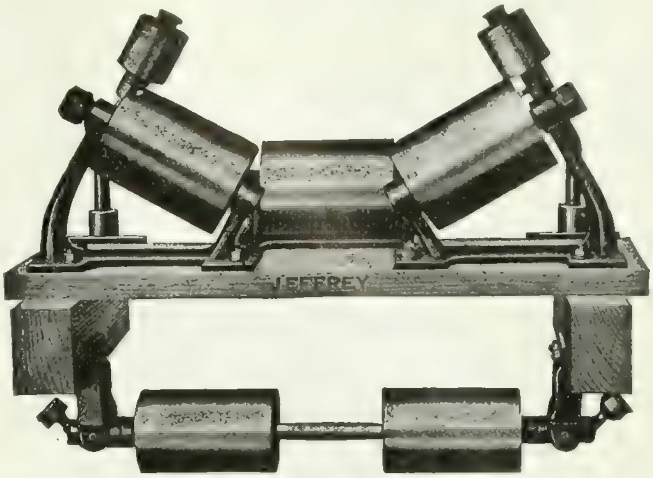

Fig. 22.

(1) Similarity of design for all belts, both flat or troughed, enables a few spares to be kept in stock which will suit any number of conveyors.

(2) If it is found necessary to alter the width of a band, the old style of rollers would be useless, but with these unit rollers all that need be done is probably a little resetting and increase of the number, and the belt will be quite as perfect as it was in its original state.

(3) Probable lessening of the cost of manufacture due to all the parts being alike, but on this point the author has no figures available.

In addition to these points Messrs. The Stephens-Adamson Manufacturing Company state that their rollers are practically dust-proof and indestructible, and further, owing to the method of construction the rollers are much lighter than the other type.

Another advantage claimed is a saving in power, and the makers state that for a flat level conveyor using this type of carrier 40 per cent. of the power required for a conveyor of the old type would be saved.

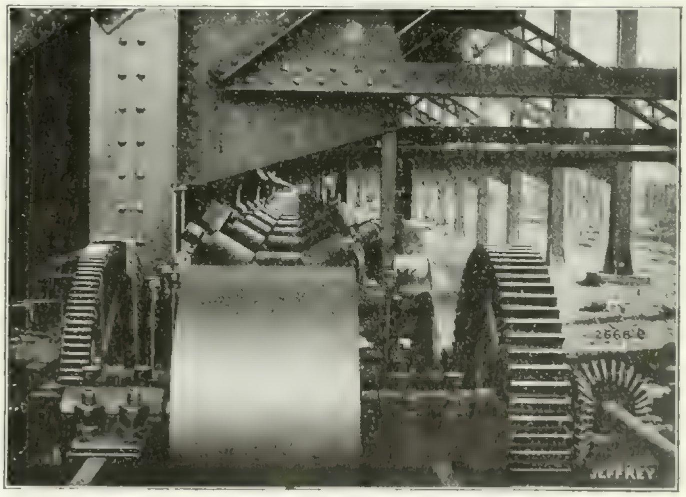

Fig. 23.

This appears to the writer to be rather a big amount and he assumes their figures are based on a conveyor running light, so that the actual percentage of saving on a conveyor fully loaded would be something less than this.

Fig. 23 shows a typical arrangement of the driving gear of a modern conveyor. It will be seen that the motive power is supplied by a shaft running parallel with the length of the conveyor, and this is transmitted by a pair of mitre wheels to a shaft at right angles, and thence through straight teeth cast iron gear wheels to the drum shaft.

Fig. 24 gives a very good idea of the general layout of a band conveyor installation, and shows two bands conveying stone.

The last two illustrations have been supplied by the Jeffrey Manufacturing Company.

The rapid strides that have been made in the manufacture of these conveyors during the last few years is very apparent to all those in any way connected with their use and with the improvements made and decrease in the cost of manufacture their field of usefulness has been extended into practically every branch of manufacture.

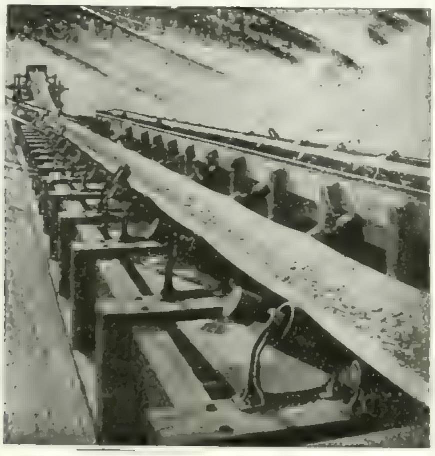

Fig. 24.

In conclusion, the writer would like to impress upon purchasers of this type of machinery that the great point to aim at is simplicity in general outline and details. Then, after buying a good conveyor, spend a reasonable amount on same for attention, such as oiling, overhauling and cleaning. If this is faithfully carried out the best results will be obtained, both as to efficiency and maintenance.

BITUMINOUS ROAD SURFACES.

In a paper before the American Society of Civil Engineers, Mr. A. W. Dean takes up the question of superficial coats of bituminous material with or without stone for road surfaces.

Bituminous pavements of various types have been in use for many years, whereas bituminous surfaces are of recent adoption. The early superficial applications of oil were made largely for the purpose of dust prevention on dirt roads, a crude light oil being used, having very little binding quality. The advent of motor-vehicle traffic, however, has led to a very extensive use of bituminous surfaces, not only for the purpose of dust laying, but for the preservation of the roads. As a natural consequence, many experiments have been tried by road authorities to determine what methods and materials are best adapted to overcome the difficulties encountered, and by producers to determine what quality of bituminous material can be manufactured at a minimum cost to meet the requirements of the road authorities. Being still in the experimental stage, final conclusions regarding methods and materials are obviously impossible. It has been clearly demonstrated, however, that no uniform specification can be adopted defining a material which will produce a good bituminous surface on roads of every type and under every condition of traffic. Experience has shown, for instance, that while a heavy refined tar may be used to advantage on a macadam road, it is of no value as a surface application on an ordinary gravel or dirt road.

For surface treatment of dirt roads, a light oil helps somewhat to preserve the road, in that it prevents the particles composing the surface from blowing away, and assists, to some slight degree, in hardening the surface.

For surface treatment of gravel roads, the best results appear to be obtained by using an asphaltic oil of what might be termed medium viscosity, or by approximating the maximum viscosity that will permit application through an ordinary distributor at a temperature of 50 degrees Fahrenheit.

For surface treatment of broken stone roads, a light or medium oil acts mainly as a dust layer, yet if frequently applied it preserves the road to a very appreciable extent. In determining what bituminous material would be the most economical and advantageous for the preservation by surface treatment of broken stone roads, a knowledge of the traffic over the road is absolutely essential. If the road is subjected to light motor-vehicle traffic and light team traffic, with the motor vehicles predominating, experience has shown that an asphaltic oil, of such viscosity that it requires heating to at least 250 degrees Fahrenheit before application, forms a bituminous surface which withstands the traffic and thoroughly preserves the road for a period of time depending partly on the quality of the material and workmanship and partly on the quantity of traffic.

Chemists do not agree unanimously on definite requirements for bituminous materials to be used for surface applications, and, as this method of treatment of roads is of such recent practice, it is probable that at least two years more must elapse before positive specifications can be drawn. Producers claim that the best oils for the purpose contain 90 per cent asphalt. Residuum oils placed on roads in Massachusetts early in the season of 1909, still show life, and an indication of durability for a considerable time to come, and this fact would show that, while natural asphalts may possibly be superior, the residuum asphalts are, nevertheless, suitable for the purpose.

Fully as important as the quality of the bituminous material is the quality of the workmanship in applying it. In the preparation of the broken stone surface, extreme care should be taken to sweep and remove every particle of dust and dirt, so that the stones will be absolutely bare. Many failures of bituminous surfaces can be traced directly to the improper preparation of the broken stone surface, the heavy oils being distributed on dusty and dirty sections, and, consequently, peeling up through lack of adhesion. In order to get the best adhesion of asphaltic oils, it appears that the stone surface should also be somewhat moist ratner than extremely dry. In distributing the oil, if the stone surface is comparatively new and smooth, the best results appear to be obtained by applying the oil under pressure in two applications, each of ¼ gallon per square yard, covering the first application with grit or pea stone before putting on the second, and covering the second application with the same material as soon as possible after it has been made. The effect of applying the material in this manner is to make the distribution more uniform and prevent surplus oil from flowing on the sloping crown of the road, thereby causing ridges and bunches to appear after the work has been done. If the stone surface is full of slight depressions, however, a single application of ½ gallon per square yard, applied with or without pressure, has proved satisfactory. The oil tends to run to the depressions, causing a slight surplus of oil in them, so that when the grit is applied on top of the oil, the portions over the depressions absorb more grit, consequently rendering the road smoother.

The character of the grit or other material used for covering the oil is of great importance. Where the traffic is confined exclusively to motor vehicles, sand appears to be as effective as any material for covering, but if there is some steel-tyred horse-drawn traffic, a coarse material like pea stone or fine gravel is necessary.

The cost of a bituminous surface as just described will vary, of course, with the availability of the material to be used for covering, and the length of haul of all materials. In Massachusetts, during the last four years, several hundred miles of macadam road have been improved or preserved by a bituminous surface of this kind. The average cost during 1910 was a little less than $0.08 per square yard, and, during 1911, a little more than that price, with labor costing from $1.75 to $2.00 per 8-hour day, and asphaltic oil costing $0.06 per gallon delivered in cars.

In maintaining these bituminous surfaces a re-treatment of about ¼ gallon of bituminous material per square yard is only made on those places from which the bituminous material has disappeared. The present condition of these roads indicates that the expense for patching and sanding in 1912 will not exceed $0.01 per square yard, in which case the total expense of maintenance for four years will have been $0.1076, making the average cost $0.0269 per square yard, or approximately $236.72 per mile per year for a 15-foot road. Whether such a surface on a macadam road will withstand the traffic of heavily loaded motor trucks cannot now be determined, as such trucks have not been in service sufficiently long to permit of determinations.

On roads where the prevailing traffic consists of steel-tyred horse-drawn vehicles, this application of bituminous surface, consisting of heavy asphaltic oil and grit, has proved unsuccessful, in most instances, the surface being cut and dented to such a degree that it soon disappears. On such a road, it is possible that a heavy, refined tar surface may be economical, or it may be economical to use oil of a lighter grade, applying it with sufficient frequency to keep the surface of the stone covered with oil at all times.

EXPERIMENTS ON CONCRETE WATER BARRELS AS APPLIED TO FIRE PROTECTION OF RAILWAY BRIDGES.

By Hunter M'Donald.

The maintenance of water barrels for fire protection on bridges and trestles may seem to the uninitiated to be a comparatively small matter. To the person upon whom the responsibility for their maintenance and efficiency rests the matter presents an entirely different aspect. To be efficient, water barrels must be kept full of water and be easily accessible, which essentials entail the following requirements:

The water must not freeze; the barrels must not leak; the water must not evaporate or be drunk by cattle; frequent inspections must be made; the barrels must be filled when installed and frequently refilled; the barrels must be placed at proper intervals for effective use in case of fire; they should be provided with small cans or vessels, in which the water can be carried to the point where it is needed.

The principal damage other than fire risk, caused by freezing, is that it makes the barrels leak. This can be prevented to some extent by fastening in the barrel a stick running in a slanting direction from near the top to the bottom. The addition of salt will, of course, lower the freezing point, but will not prevent freezing. The only consolation to be derived from frozen water barrels is the fact that fires in bridges are not likely to occur in freezing weather.

Where water barrels are completely buried in the earth at the ends of the trestles, they seldom leak until the wooden staves become rotten, which occurs in about four years. If wooden barrels are not buried they require frequent refilling If carefully covered to prevent evaporation, the interval of filling is lengthened. Should the water in the barrel get low from any cause, the barrel is usually permanently injured by having the tops of the staves dry out—a condition very difficult to remedy. A prolific cause of leaky barrels is the tendency of the idle man or boy with a gun to use them for targets. Axes and hammers are sometimes used as a means of destruction.

Barrels must be substantially covered to prevent evaporation. When tight barrels are buried at the end of the trestle and well covered, refilling is seldom needed more than once a year. Covering is also necessary on account of the tendency of cattle in the dry season to drink the water up. It seems impossible to cover them so tightly as to prevent large crops of mosquitoes from being raised. Barrel covers which sink below the outer rim of the barrel are very advantageous, as they catch all the rainfall and allow it to run into the barrel. Where no leaks occur, this is sufficient in many climates to keep the barrels full.

Unless inspections of the barrels are made at frequent intervals by a responsible officer, they are likely to go to pieces early and be absent or empty at the time most needed. It is not sufficient for the inspector to merely call attention to the defects, but each one should be followed up immediately and remedied.

When barrels are first installed, they should be filled by the party installing them; after this, they should be given over to the section foreman, whose duty it should be to keep them properly filled.

Water barrels can be effective only in the incipiency of a fire. More effective means must be had when the fire has assumed some headway. How to get the water out of the barrel and put it on the fire is a question. On some divisions oyster and tomato cans are sunk to the bottom of the barrel or fastened to the underside of the top by a wire. Sometimes an old paint bucket is used and sometimes a box made of heavy plank. The object is to use something that nobody wants to take away. It is almost impossible to maintain such vessels in the barrels, and the best way is to assume that the person who discovers the fire will use his hat, shoe or something else until organized help arrives. In studying the water barrel question the concrete barrel has come in for its share of discussion, and two experimental barrels were made two years ago. They have the self-feeding top—that is the top is depressed so as to catch the rain water. Neither has required refilling. Both have proved themselves to be proof against bullets fired from a 38-calibre revolver. Below is a table of the estimated cost of making these barrels:

---

* From a paper presented before the Engineering Association of the South, January 22nd, 1912.

Covers:		
Galvanized iron, 5 square feet at 3 cents..	$0.15	
Hinge, bolts, rivets and wire, 5 cents....	.05	
Cost of making, one man one hour.......	.20—	$0.40
Barrel:		
17 square feet expanded metal (0.6 pound, a foot) at 5 cents	$0.51	
10 cubic yards 1:2:4 concrete at $2.40....	.24	
Cost of forms (assuming twenty-five barrels to one set)	.10	
Cost of labor for making barrels at 15 cents	.30—	1.15
		$1.55
Add 10 per cent. for engineering and incidentals..		15
Total cost		$1.70

Another experiment has been tried, consisting of a concrete box let into the ground all but about one foot, this upper part being used for the number of the trestle.

It is believed that good concrete water barrels, with metal tops, can be made for $1.30 each when made in large quantities. The wooden barrel is the most expensive of the two, considering its capitalized cost on a basis of six years' life, which is reasonable, leaving out all consideration of increased cost of maintenance.

Other experiments have been made, using galvanized iron forms, and poultry netting reinforcement. Plastering the mortar on has not resulted in tight barrels, but 1:2:4 concrete cast and rammed into forms has given good results. Experiment is also being made with joints of 24-in. clay pipe with concrete bottom, with the bell set upward and buried in the ground.

The ballasted deck trestle is rapidly becoming the [illegible] and it is thought that in the future the water barrel will seldom be needed.

◆

AMERICAN TEST OF WIRE ROPE.

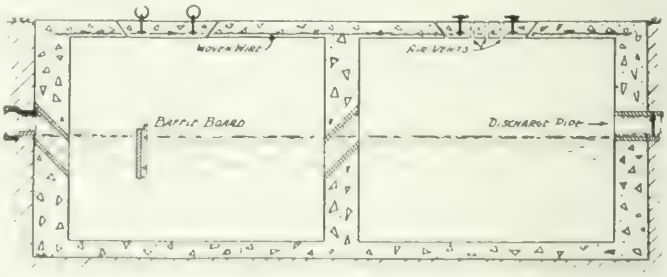
[illegible] test? (Some authorities believe this to be superfluous) and [illegible] of abrasive tests? (6) Biggart, Stone and others have proposed and made tests in which the life of cables, and other properties, are investigated by passing them over a series of pulleys direct and reversed, the cables being subject to different direct tensions. What is the relative value of such tests, and how should they be carried out? (7) Samples of cables have been taken under actual service conditions after a number of years' usage in mine or elevator service, and tests compared with the unused original material. Is anything in this line desirable? (8) Are any other physical tests necessary (9) Chemical tests will be made. What are the suggestions in this respect (10) What number of duplicate tests is suggested for any one type or specimen? Tetmajer used two in his tests. Three would seem more desirable. For the individual wires he used eleven. Would not a lesser number, say six, be sufficient?

◆

SEWAGE DISPOSAL FOR COUNTRY HOMES.

The general use in country homes of the modern conveniences of the bath and toilet has made necessary some effective and inexpensive means of disposing of the sewage. Otherwise the drinking water will be polluted and the health of the family endangered. Entire satisfaction is obtained by the use of the septic tank, which is nothing but a long water-tight cistern through which the sewage passes very slowly and evenly. The purified sewage may be discharged into an ordinary farm drain tile.

Although the odor from a small septic tank is practically unnoticeable, yet it is best to locate it at least a hundred and fifty feet from the house. Choose a spot where it can be sunk to ground level and will be out of danger of flood waters. The tank should be large enough to hold the entire sewage for one day. For a family of eight to ten, plan a concrete tank of two compartments each 4 by 4 by 5 feet long. Since the top and bottom are each 4 inches thick and the division and sidewalls 8 inches, dig the pit 4 feet 8 inches deep, 5 feet 4 inches wide and 12 feet long.



Cross-Section Through Tank.

If the ground stands firm, only inside forms will be needed. Make two, each 4 by 4 by 5 feet long. Old 1-inch lumber will do for the siding. The compartment into which the sewage first enters is called the "charge tank." In each end of the wooden form for this tank cut openings for a 5-inch tile with the lower edge of the hole 10 inches above the bottom of the form. Through each of the sidewalls of this same form, [illegible] inches from the [illegible] end and 1½ and 2 feet above bottom, bore 1-inch holes and insert in them greased wooden pegs extending 4 inches into the future sidewalls. Likewise, in the other form for the discharge tank, cut openings for a 5-inch tile, this time with the lower edge of the hole [illegible] feet above the bottom.

Mix the concrete one part Portland cement to two parts sand to four parts crushed rock, or one part cement to four parts of gravel. Place the 4 inches of concrete in the bottom and trowel to an even surface. Immediately set the forms in place so as to leave room for 8-inch division and sidewalls. Fill the forms with mushy wet concrete. At the proper heights insert the 5-inch drain tile through the holes in the forms. Be careful that the outside end of the inlet tile to the charge tank is 2 feet and its other end 16 inches above tank bottom. The pipe leading from the charge tank is also set at the same sharp slope. The outlet tile from the discharge tank is 2 feet above bottom and with both ends level. By this arrangement of pipes, the sewage is kept in the tank to the depth of 2 feet and the ends of the tile in the charge tank are trapped or air-sealed, which aids the activity of a certain kind of bacteria. Likewise, other bacteria are developed in the discharge tank by means of the free circulation of air through the discharge drain tile and holes in the manhole cover.

After the sidewalls are three days old, floor over the top of the forms and prepare to lay the 4-inch concrete top. As molds for the manhole covers, have the tinner make two round bottomless dishpans, 18 inches in diameter at the bottom and 24 inches at the top. Grease these tin molds and set one on the wooden floor over each compartment. Bore six 1-inch holes in the floor inside the one manhole mold over the discharge tank and insert in them greased pegs projecting upward six inches.

Place one inch of concrete over the entire floor and at once lay on it, crosswise the tank, strips of heavy woven-wire fencing 5 feet 2 inches long, or ⅜-inch rods running in both directions and spaced one foot. Likewise reinforce the manhole covers. Immediately place the remaining 3 inches of concrete and do not stop until the tank top and manhole covers are finished. Provide two lifting-rings for each cover by setting in them halves of old bridle-bits, or hitching-post rings, fitted with knobs of wire or with nuts and large washers. If a square wooden manhole mold is used, the concrete cover cannot be cast at once. In such case, carefully remove the wooden manhole form five hours after the top has been finished. Three days later mold the cover the same as for the tin form with this important exception—place heavy paper or cardboard around the edges of the opening to prevent the fresh concrete of the cover from setting to the old concrete.

When the top of the tank is ten days old, lift off the manhole covers, saw openings in the wooden top and remove the forms. In the holes made in the sidewall by the greased wooden pegs, insert ½-inch bolts and set them with mortar. To these bolts fasten the 1 by 12-inch wooden baffle-board which extends across the tank and breaks up the current of the inflowing sewage. To carry the sewage from the house to the tank, use 4-inch sewer pipe laid with tight mortar joints. Connect the discharge end of the tank with a string of drain tile.

The materials required for the tank described above are 5½ cubic yards of crushed rock, 2¾ cubic yards of sand and 9 barrels of Portland cement. If good pit gravel is used, no additional sand will be required.

When the septic tank is two weeks old it may be put to use. It will need cleaning at intervals of two to three years. By its use the health of the family will be protected and life in the country home will be made much more comfortable.

◆

A NEW LINE OF BLOWERS DESIGNED FOR TURBINE DRIVE.

It is an established fact that turbines driving pumps or blowers in power plant service, where the exhaust is used to heat feed water or for steam heating, are more economical than the main driving units, even if these are run condensing. With the exception of a slight loss through radiation, what heat is not converted into mechanical work is either returned to the boilers or utilized, so that the heat efficiency closely approaches 100 per cent. This certainly commends turbo-auxiliaries as economical as well as reliable to maintain overall plant efficiency.

However, as is well known, turbine power increases with the revolutions per minute up to a best speed that is invariably higher than that of ordinary turbine pumps or ordinary blowers. The writer has in mind a small steam turbine that develops 15 brake horsepower at 1000 r.p.m. and 40 horsepower at 3500 r.p.m. with the same pressure and total steam per hour. A larger turbine of another type develops 80 brake horsepower at 600 r.p.m. and 160 brake horsepower at 1600 r.p.m. with the same pressure and total steam per hour. The best pumps or blowers for these two turbines would therefore be the ones having economical speeds close to the higher turbine speed figures in each instance.

With these considerations in mind, Mr. C. V. Kerr, inventor of the original Kerr Turbine, has designed, and McEwen Brothers of Wellsville, N.Y., are now marketing a new line of pumps and blowers for turbine drive, having best speeds practically the same as those for the turbine and having an economical range within 25 per cent. above, to 25 per cent. below, rated capacity.

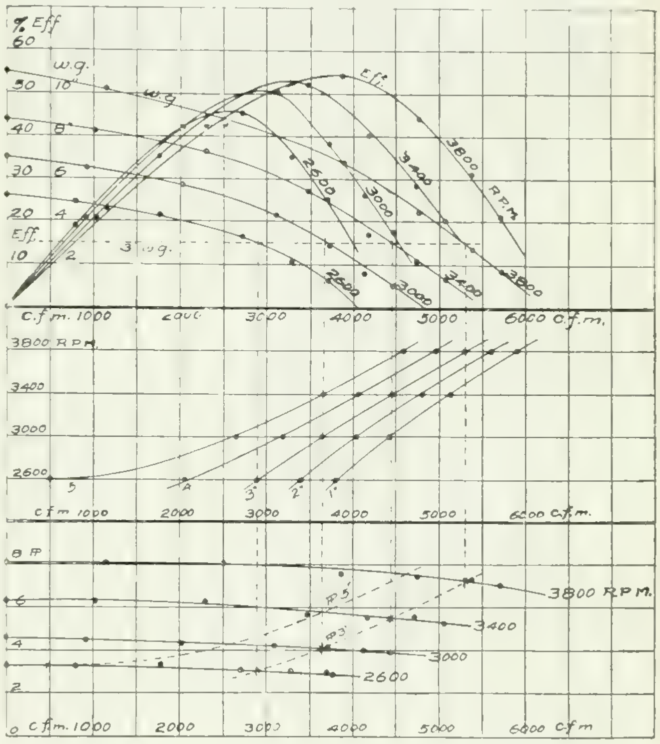


Fig. 1. Test of 16-in. Blower with helical impellers.

The blowers, are built in two types, the smaller sizes with double helical runners and the larger with increase pitch propellers. The manufacturers claim for both types a unit economy or steam per air horsepower better than ever reached before, especially on forced draft pressures. Both types have the runners opposed and balanced for high speed and have a central deflector to prevent cross flow. The runners are removable endwise and may be reversed on the shaft for right or left hand discharge. The bearings are lead-bronze, or babbitt lined, ring oiled and dust proof. The helical runner type has a solid cast-iron volute, and the propeller type is made with cast-iron sides and steel volutes.

The former, is designed especially for forced draft for forges and furnaces and in connection with underfeed stokers. Tests on a 16-inch blower of this type, and made with a calibrated steam turbine, Pitot tube and a series of nozzles showed the results indicated in Figure 1.

The propeller type blower, shown in Figure 2, has blades with an increase-pitch helical surface to reduce the shock losses due to impact at entrance. The kinetic efficiency of these blades is said to be high and in connection with the volute casing, reduces the discharge velocity to produce pressure instead of eddies which decrease the efficiency and delivery pressure of an ordinary disc fan.

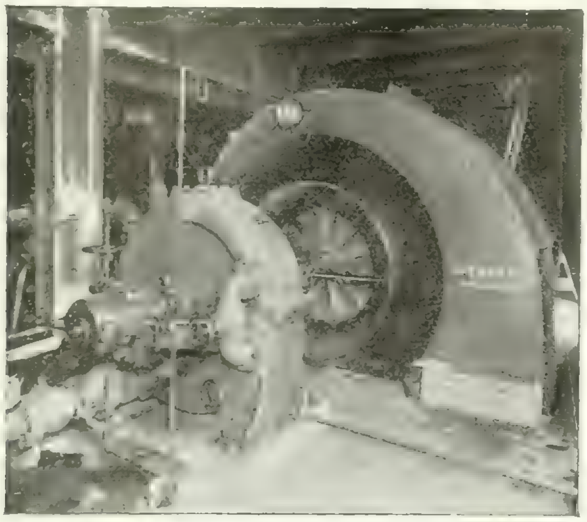

Fig. 2. Blower in the plant of the Brooklyn Edison Company, Maximum capacity, 80,000 cubic feet of air per minute at 4-in. total water gauge and 1500 r.p.m.

Losses from back flow are prevented and a strong construction assured by dovetailing the blades into a solid hub. It is evident too that as the pull of centrifugal force is radial there is practically no blade distortion at high speed. A [illegible] at any number of points on the line of [illegible] and running at the same setting [illegible] producing different pressures [illegible] the same speed and [illegible].

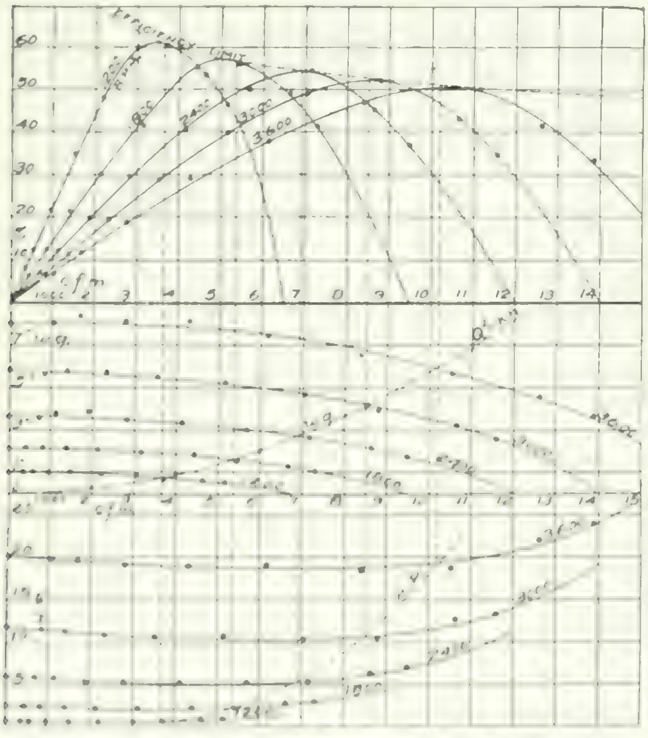

Fig. 1. Test of an 18-in. Propeller Blower.

The performance of a blower of this type, the smallest of the series offered is shown in Figure 3.

These tests also were made with a calibrated turbine, Pitot tube and a series of nozzles at the end of a duct. The smoothness to which the points plot can be taken as an indication of accuracy of observation. The relation of the parabola of highest efficiency, $Q^2=KH$, (Q=quantity, H=head, K=constant), to the dot at the top of efficiency curve located by the same nozzle in each case is worthy of note. This suggests that if the discharge connection is reduced to the proper area the blower can be operated always at highest efficiency, regardless of speed. Beyond this throat the duct should be expanded to reduce velocity losses.

The head or pressure curves show the facility with which a number of these blowers can operate in parallel on the same duct, and how rapidly the dischage increases at constant head with increase of speed. The variation of power required as the blower is worked along the path of highest efficiency is also worthy of note.

Incidentally, the test results show that this blower, developed especially for forced draft work, is practical with either steam turbine or motor drive. On account of high efficiency and noiseless running at required pressures this blower is also useful for heating and ventilating service, including mine ventilation.

◆

THE STRENGTH OF CROSSARMS.

The strength of crossarms has been tested by the Forest Service of the United States and it was found that for all ordinary pole-line conditions the crossarm is stronger than the pole. The arms tested were of Douglas fir, long-leaf pine (50 per cent. to 100 per cent. heart), short-leaf pine (plain and creosoted) and white cedar. The arms were about 3 x 4 in. in section (somewhat varying) and 6 ft. long, with three 1½-in. vertical pin-holes on either side of the centre. The two inner pin-holes were each 8 in. from the middle. For the test the crossarm was gained and bolted to a short piece of pole and the outer end of the attachment bolt was supported by an iron strap bracket. Vertical load was applied by the testing machine acting on a series of distributing levers, which brought equal load to bear on rods passing through the six pin-holes. The maximum load which the crossarm carried ranged from 4,800 to 10,240 lb. (based on a standard section of 3.16 x 4.10 in., the average size of Douglas fir arms). The crossarms of long-leaf pine were strongest, ranging from 9,000 to 10,240. Douglas fir and short-leaf pine were slightly weaker. White cedar showed a strength of only about 5,000 lb.; the failure in the case of white cedar was in nearly all cases a brash tension failure. In each case the corresponding lateral strength of the arm would be about 80 per cent. of the vertical strength, or about 4,000 lb. for the white cedar crossarm. Since tests of poles have shown that their resistance to side pull is rarely as high as 3,000 lb., and usually below 2,000, it is seen that the crossarm is the stronger. The values above given are all averages of a considerable number of samples.

The compressive strength of the wood in these crossarms ranged from 4,700 lb. per sq. in. for the white cedar to 9,000 lb. for the better samples of long-leaf pine and about 7,000 lb. for Douglas fir. Short-leaf pine ranged from 7,300 for the plain arms to something below 6,000 lb. per sq. in. for the creosoted arms.

It is concluded that for standard 6-ft. crossarms the question of strength need not enter into calculations of line construction except in rare cases of abrupt change in grade. The ability of the timber to resist decay, and methods of preventing decay, are much more important.

THE BLOOR STREET VIADUCT.

The following is extracted from a report by Commissioner of Works Harris, of the city of Toronto, to the Board of Control on the proposed Bloor Street viaduct:—

> "We are making a thorough survey of the route adopted for the Bloor Street viaduct, and taking the necessary levels and cross-sections, to enable us to prepare plans and specifications for the proposed bridge. I have gone into the matter thoroughly with Mr. C. W. Power, Engineer of Railways and Bridges, who advises me that a concrete bridge would involve minimum maintenance charge, but that other considerations enter into its construction, which renders it inadvisable to use this material. Extensive bridges of this class are, as yet, an experiment, and we do not think that the city of Toronto should make any investment along experimental lines, especially where the issue is so much in doubt. It is found, frequently, in structural concrete, that the slighting of a comparatively small portion of the work destroys the integrity of the whole structure. **Concrete bridge design is not well understood, while that of steel is upon an assured basis.**"

Mr. Harris surely did not desire that the last sentence of the above should be read literally. If he did mean it, we can only say that Mr. Harris has misunderstood what he has been told regarding concrete bridge design. To the question of whether concrete or steel should be used for the Bloor Street viaduct, we have nothing to say. That is a question to be decided on the local conditions—foundations cost, maintenance, suitability, etc. To the statement of Commissioner Harris that "concrete bridge design is not well understood" we must take issue. The analysis of stresses and the knowledge of the action of concrete is to-day on as high a plane as any other branch of structural design. Commissioner Harris is on uncertain ground when his duties compel him to report on work demanding a knowledge of engineering.

◆

WATER STERILIZATION.

In an engineering contemporary the treatment of drinking water by means of violet ray sterilization, in Chicago, is described. The plant is the initial installation for sterilizing water by this means in a commercial way in America, and it is, therefore, interesting to note what results have been obtained. One of the most interesting features of it has been the experience with air. It seems that the water to be treated must be perfectly free from turbidity, either in the form of solid material or in the gaseous state as from liberated air. Erratic results were obtained with a perfectly clear water until the experimenters one day noticed through the peek-hole of the lamp that the water in the sterilizer appeared cloudy to the eye, although the final product was crystal clear. The installation of a tank to eliminate the air solved this problem. In an $11\frac{1}{2}$-in. diameter sterilizer the proper position for the lamp was found to be $2\frac{1}{2}$ in. from the surface. The brilliancy given to water by treatment with aluminum sulphate seems to be particularly advantageous, in permitting the rays to penetrate the water.

There is some evidence to indicate that violet rays kill spores as well as vegetative bacteria. Ordinarily, a sterile water offers a nidus for a host of harmless organisms, but the analyses of samples taken from commercial bottles at Chicago at various intervals up to a month gave insignificant counts. Such results are manifestly dependent on the care with which the empties are washed. It is to be hoped that further corroborative results on a number of these points, as well as the limits in the rate at which water can be treated, will be obtained. The current cost at this plant is necessarily so low that it is hardly a factor in the total expense.

However, assuming a 110-volt, 4½-ampere lamp capable of sterilizing 150 gallons of water per hour, and estimating the cost of electricity at $25 per kilowatt per year, or 0.3 cents per kw-hour, the cost for 1,000,000 gallons is only $10, a figure not beyond the reach of those who wish a final polish on a water already coagulated, settled and filtered, and who do not care to take the possible chance of a taste and odor due to a chemical sterilization. For small domestic supplies, such as high-class residence towns, hotels and bottled-water service, this new method of meeting the ever-increasing demand for a more safe drinking water will bear study.

ANOTHER SEWAGE DISPOSAL SCHEME.

We noted in last week's issue that the United States Secretary of War had decided to refuse the application of the Sanitary District of Chicago for the right to divert an increased amount of water from Lake Michigan. This question has been up for discussion for some time, and Canadians will be pleased to note the action of the Secretary of War. A new scheme has now appeared, which, if allowed to materialize, would cause ill effects as great as increased diversion of water for the Chicago Drainage Canal.

The municipalities along the Niagara frontier, from Buffalo to Lewiston, in New York State, are investigating the possibilities of joint action with regard to their sewage disposal. It has been suggested that the towns and cities in that vicinity collect their sewage in a trunk sewer tunnel, which would run from Buffalo, on Lake Erie, to Lewiston, on Lake Ontario. As the fall from Lake Erie to Lake Ontario is over three hundred feet, by this means it is expected that about 250,000 horse-power would be utilizable by the installation of a power house at Lake Ontario or on the Niagara River. Leaving aside the practical difficulties, such as irregularity of flow, necessity of a pressure tunnel, and the consequent difficulty in collecting sewage from the towns along the route, etc., the promoters of this visionary scheme neglect to consider the effect of dumping the combined sewage of practically a million people, without treatment, into Lake Ontario. It is extremely likely that a good deal of opposition will develop if it is attempted to carry out the plan. The scheme, on the face of it, looks like a veiled attempt to secure water power privileges for the interested municipalities. No doubt the Canadian Branch of the International Joint Commission and the Commission of Conservation will look after Canadian interests when the right time comes. Their energetic action in the case of the Chicago Drainage Canal diversion cannot be too highly commended.

EDITORIAL COMMENT.

It is stated that President Maurice Connolly, of the Borough of Queens, New York City, has prepared an ordinance providing for a tax of $1 on every funeral cortege which passes through the borough, for the purpose of establishing a fund for maintaining the roads of the borough. The proposed tax would be a revival of a former ordinance covering nearly the same ground. Practically all the convenient routes which lead to the several cemeteries in which the dead of New York are buried lie in the Borough of Queens. The income which would be derived from such a source is estimated to amount to about $100,000 annually. The present state of Yonge Street, Toronto, might warrant the York County Highway Board raising a fund in a similar way. There are four cemeteries on Yonge Street, and no doubt the annual income from such a source would be large. We offer this suggestion to them gratis, if it will in any way help in Yonge Street improvement.

* * * *

Ottawa is reaping the harvest from the council's policy of procrastination with regard to the water supply situation. Two typhoid epidemics in two years would appear sufficient to justify more action and less talk.

LETTER TO THE EDITOR.

CONCRETE FOR THE BLOOR STREET VIADUCT, TORONTO.

Sir,—According to the reports in the daily press the Commissioner of Works of the city of Toronto has recommended the city council to consider only the use of steel in the construction of the Bloor Street viaduct. He is reported to have added to this recommendation some reflections on the permanence of concrete construction which are liable to recoil on his department which, under his predecessor, has been a very successful user of concrete on a large scale, and in some novel and unusual ways. Doubt as to the strength and permanence of the Harbord Street bridge and of the poles of the city's hydro-electric system may be counted on to follow such comment, and we shall probably hear from Pro Bono Publico recommendations for the thorough painting of these and other structures before their permanence is seriously impaired.

It is unfortunate that concrete construction should thus seem to be attacked by one who, from his position, will be looked on by outsiders as an expert. By those who are able to appreciate the magnificent possibilities of concrete work this action will be taken as amusing or deplorable, according as they view it as a personal opinion or as the policy of the engineering department of a large city. By the general public it will be taken either as a sweeping condemnation of concrete or as another instance of the worthlessness of expert advice. In any event, the city council will be well advised if the recommendation is rejected.

Whether concrete or steel is the cheaper material there can be little doubt that from an architectural standpoint a much more pleasing effect can be secured from concrete. There are several steel viaducts in the city of Toronto, but only one of these, the Wilton Avenue bridge, has any artistic merit. The remainder stand as examples of what the bridge engineer can create when cheapness is the first and only consideration. Several of these refuse really to stand, but vibrate to such an extent that the city has given up the attempt to keep them lighted with electric lights. They are a continuous source of expense, and call for frequent renewals of the wooden floors and sometimes call in vain for paint. They were at their strongest the day they were erected and are weaker for every day they stand—concrete built at the same time would now be over ten per cent. stronger. A fine effect is, of course, possible with steel, but Toronto can only show one example in steel, while the

Harbord Street arch and the concrete bridges at Centre Island show what the works department has accomplished in the past in very satisfactorily harmonizing structures to their surroundings.

Great stress is laid on the fact that good foundations must be obtained for a concrete arch, and this elementary engineering consideration is granted. The steel superstructures of the skyscraper office buildings can stand an amount of settlement which would wreck a concrete arch, but they are carried to rock on concrete footings. The foundations of a steel viaduct ought to be at least as secure, and, if made so, can as safely carry a superstructure of concrete as of steel. As a matter of fact, it is doubtful if the foundations for the Bloor Street viaduct would require to be carried as far down as the piers under the C.P.R. building. In the absence of information to the contrary it is fair to assume that only ordinary difficulties would have to be overcome in getting down to depth.

The point has been raised that failures of concrete structures have occurred. Leaving out the "tu quoque" arguments of the failure of brick and steel which prove nothing concerning concrete, the fact need only be emphasized that in every case the contributing cause was outside entirely of the material used—dishonest or unskillful workmanship or design, not poor material.

One argument on which might be poured the choicest sarcasm of a Macaulay flaying a Montgomery is that it is inadvisable for the city of Toronto to take the lead in using concrete for a work of such unheard-of magnitude. With a graduate of Toronto University building the largest steel truss bridge in the world, another responsible for the foundations of most of the office buildings in America and a Toronto engineer building concrete arches unsurpassed for magnitude in Canada, it is time some one awakened the Rip-van-Winkle responsible for this amazing argument. Without leaving this continent for examples we can find one viaduct with foundations going to double the depth required, another of double the proposed height, another of double the length, and still have left the notable achievement at the Florida Keys of one running over two miles over the ocean. If these are too far afield we shall be content to mention that the pioneer work has been done by Port Arthur and that before the Bloor Street viaduct is designed in steel the city of St. Catharines will have one of concrete 70 feet high and 700 feet long.

Were it not for the size and importance of the city of Toronto it would not be worth while to take up this matter seriously. But we have here a case in which steel is to be recommended to the express exclusion of concrete when the latter is necessarily permanent as against the certain deterioration of steel, whence an artistic architectural effect is certain to be obtained in concrete and almost certainly not in steel, and where it is within the bounds of possibility that concrete construction may be cheaper in first cost and is certain to be cheaper if a fair valuation is placed on maintenance expenses.

The Canadian Cement and Concrete Association is not opposed to steel construction and will not oppose steel for the Bloor Street viaduct if a committee of engineers should recommend it. The stand taken by the association is that the city of Toronto has much to gain and nothing to lose by rejecting the present recommendation of the Commissioner of Works and allowing concrete and steel to compete on equal terms for use in the construction of the Bloor Street viaduct.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.
W. SNAITH,
Secretary-Treasurer.

Toronto, August 6th, 1912.

PROGRAM FOR THE SIXTH ANNUAL CONVENTION OF THE ILLUMINATING ENGINEERING SOCIETY TO BE HELD AT HOTEL CLIFTON, NIAGARA FALLS, ONT., SEPTEMBER 16th to 19th, 1912.

1. Report of Committee on Progress. This report will deal with the recent progress and developments in the lighting industry both in this country and abroad.

2. A report of the Committee on Nomenclature and Standards, which will deal with certain definitions and terminology of illuminating engineering.

3. "Steel Mill Lighting"—a report of the committee on illumination of the Association of Iron and Steel Electrical Engineers—to be presented by the chairman, Mr. C. J. Mundo.

4. "High Pressure Gas Lighting," by Mr. F. W. Goodenough, chairman of council, Illuminating Engineering Society, London, Eng.

5. "The Status of High Pressure Gas Lighting," by Mr. George S. Barrows. This paper will be a collation of domestic and foreign correspondence pertaining to high pressure gas lighting.

6. "Recent Developments in Gas Lighting," by Mr. R. F. Pierce.

7. "Indirect and Semi-Indirect Illumination," by Mr. T. W. Rolph.

8. "Recent Developments in Series Street Lighting," by Dr. C. P. Steinmetz.

9. "Research Methods," by Dr. E. P. Hyde.

10. "The Problem of Heterochromatic Photometry and a Rational Standard of Light," by Dr. H. E. Ives.

11. "Reflection from Colored Surfaces," by Claude W. Jordan.

12. "Diffuse Reflection," by Dr. P. G. Nutting.

13. A Study of Natural and Artificial Light Distribution in Interiors," by Mr. M. Luckiesh.

14. "The Physiology of Vision," by Dr. T. A. Woodruff.

15. "The Efficiency of the Eye Under Different Systems of Illumination," by Dr. C. E. Ferree. This paper will be a report of a research carried on for the American Medical Association.

16. "A Proposed Method of Determining the Diffusion of Translucent Media," by Mr. E. L. Elliott.

17. "Illumination Charts," by Mr. F. A. Beuford.

18. "The Determination of Illumination Efficiency," by Mr. E. L. Elliott.

19. "An Absolute Reflectometer," by Dr. P. G. Nutting.

20. "Colored Values of Illuminated Surfaces," by Mr. Bassett Jones, Jr. This subject will be presented in the form of a series of experimental demonstrations.

21. One session will be arranged for, a potpourri, at which discussions will be in order on miscellaneous phases of illuminating engineering. It is expected that this session will bring out interesting and valuable points not particularly covered by the above papers and reports.

The scenic wonders of the Falls render possible an entertainment program which will surpass that given at any previous convention of this society.

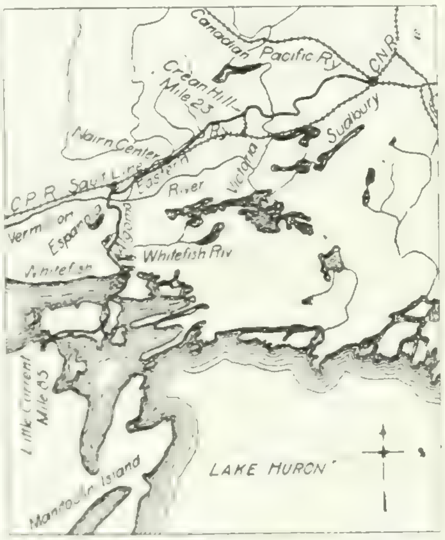
Inspection tours of the power houses and other wonderful development enterprises peculiar to this location have been arranged for.

Reduced railroad fares will be available for delegates.

THE CONSTRUCTION OF THE ALGOMA CENTRAL AND HUDSON BAY RAILWAY, AND THE ALGOMA EASTERN RAILWAY.

By R. S. M'Cormick.*

Algoma Central and Hudson Bay.—The construction of the Algoma Central & Hudson Bay was begun in the spring of 1900 by the Old Lake Superior Corporation, under the management of F. H. Clergue, a land grant and subsidy being arranged for at that time with the Canadian Government. In the spring of 1903 a continuous line had been graded from Sault Ste. Marie, Ont., to Josephine Junction, 170½ miles north, with a line extending down to Lake Superior, at Michipicoten harbor. This section, 20 miles long, was built in 1899-1900 to gain access to valuable iron mines in this territory, owned by the corporation. The grading work on the main line was not completely finished, however, as financial misfortunes overtook the corporation. Track was only laid to a point about 55 miles north of the "Soo." A large number of bridges and trestles between this point and Josephine Junction were not built, but otherwise the line was completed to subgrade.

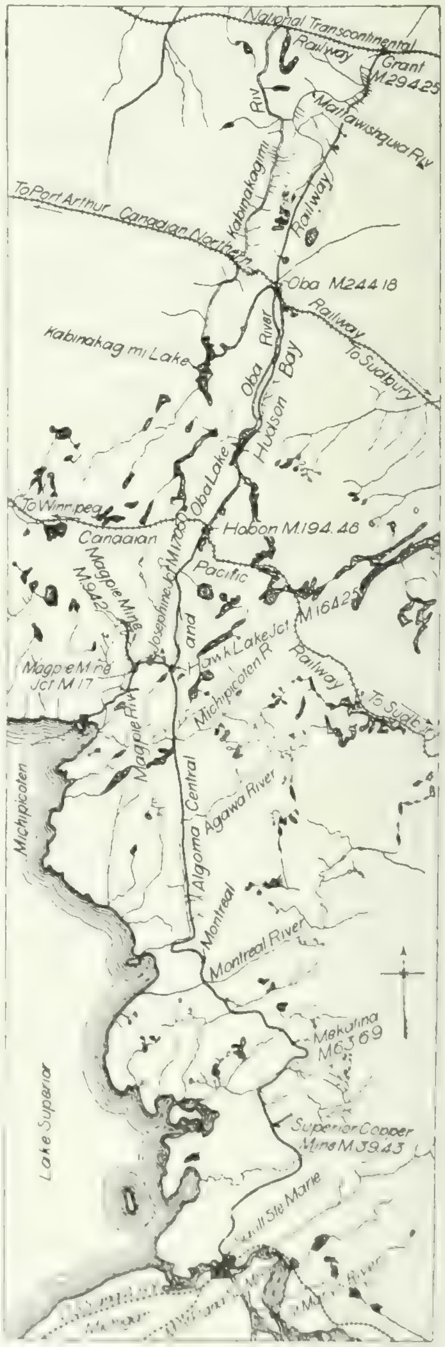


Map of the Algoma Eastern Railway.

Between the [illegible] 1908 additional track was laid to bring the end of steel at mile 68, no other work being done north of this point, however, [illegible] active measures were begun by an English syndicate to complete the road, which had, in the meantime, secured control of the Lake Superior Corporation, including the Algoma Steel [illegible] the completion and proposed extension of the railway, a report [illegible] F. H. McGuigan, of Toronto. Mr. McGuigan reported favorably on the completion and extension of the line to connect with the National Transcontinental Railway, Canada's new coast [illegible]

The necessary financial arrangements being successfully [illegible] line to connect the old grade near Hawk Lake with the Can[illegible] Hobon. S. Keemle, locating engineer, Toronto, was in [illegible] Junction, mile 170½, including regrading in cuts where slides had occurred, bringing up settled embankments, all the bridging (excepting Montreal River), track laying and ballasting.

In the meantime a spur of 9½ miles long was located from a point 17 miles from Michipicoten harbor on the line extending from the lake to the mines, northerly to a new iron mine known as the Magpie mine. In May, 1910, active work was started on this section. The company also started to repair and re-tie the upper 10 miles of the 20 miles extending from the harbor to Josephine Junction known as the Josephine branch, which had been wholly unused for over eight years. This line was in wretched shape. The ties were rotten, and as very little ballast had originally been used it was necessary to re-ballast the whole section. This work was done with company forces, with some help from the O'Boyle company.



Map of the Location of the Algoma Central & Hudson Bay Railway.

From May, 1910, to August, 1911, the work on the main line, north from mile 68 and south from Josephine Junction, the grading of the Hawk Lake—Hobon section, the building of the Magpie branch and the re-building of the 10 miles of the Josephine branch, proceeded with the usual ups and downs peculiar to railway construction work in such a country. Labor was poor and generally scarce, and bush fires, whiskey and all the troubles incident thereto [illegible] By August [illegible], 1911, the Magpie branch [illegible] practically $[illegible] The [illegible] compensated grade against [illegible]

The [illegible] from the junction to the [illegible] except for some [illegible] the river, at [illegible] per cent. compensated.

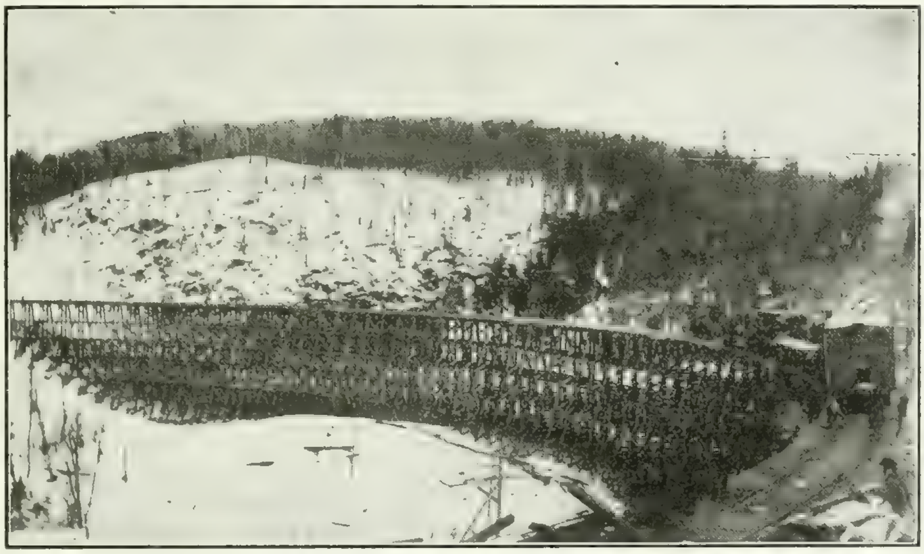
---

*[illegible]

was located. From the river crossing to the mine the line is heavy, and at mile 7½ there is a timber trestle 900 ft. long, 80 ft. high, located on a 12 deg. curve and a 1.75 per cent. grade. Up to this point the grade is 2 per cent. maximum, from here to the mine site it is 2½ per cent., 12 deg. being the maximum curve. Very large expenditures are being made by the company in opening the mine, and in addition to a plant for treating the siderite ore a model mining town is being built. This branch is laid with 80 lb. A. S. C. E. rail, with tie plates on all curves, and is most substantially built in all respects, except that timber and piles were used in bridging.

On July 15th the sub-contractors on the Hawk Lake—Hobon section finished the grading. These sub-contractors were Murdock Brothers on the lower 19 miles, and Cavicchi & Pegano on the upper 11 miles. The work was quite heavy, the grading quantities being 732,933 cu. yds. classified, 261,269 cu. yds. solid rock, 94,378 cu. yds. loose rock, and 377,286 cu. yds. common excavation. In addition there was 20,178 cu. yds. over break in rock cuttings, and overhaul amounting to 1,500,000 cu. yds. About 3,000,000 ft. B. M. of bridge timber, 40,000 lineal feet of piling, 170,000 ft. B. M. of culvert timber, 220,000 lbs. of bridge iron, 291 cu. yds. of dry stone masonry, 423 cu. yds. of cement masonry and other small items were required for this work.

The rock work was exceptionally well done, as the specifications only allowed common excavation for over break, and all the time the work was in progress this was enforced. On final estimate, however, a fair amount of over break was given as solid rock. Track laying and some ballasting was done this year, and the bridge work was completed. On January 10th, 1912, track was connected up giving a railway connection from the Canadian Pacific into the mines of the Michipicoten district. Some ballasting was also done this year.



Laying Track on Algoma Trestle.

Work on the main line completion progressed slowly from June, 1910, to May, 1911, at which time track had reached the Montreal River, mile 91½ north of the "Soo." Here a steel viaduct 1,550 ft. long and 130 ft. high located at the head of the falls 150 ft. high had to be built. This viaduct was designed in 1902 by Boller & Hodge, New York and was erected under contract by the Canadian Bridge Company. There are 1,745 tons of steel in this viaduct, and as the alinement is on a curve at each end, it was a very interesting piece of erection. The viaduct consists of tower girders supported on steel legs with concrete pedestal piers and end abutments. There are 13 30-ft. and 1 40-ft. tower girders situated on an island in the middle of the river. The intermediate girders consist of 1 85-ft., 5 75-ft., 10 60-ft., and 2 30-ft. spans. The structure is designed under the Dominion Government specifications, class 1 loading. Some poor work in concreting the piers requiring their rebuilding, delayed the erection, but track was laid over the viaduct in October, 1911.

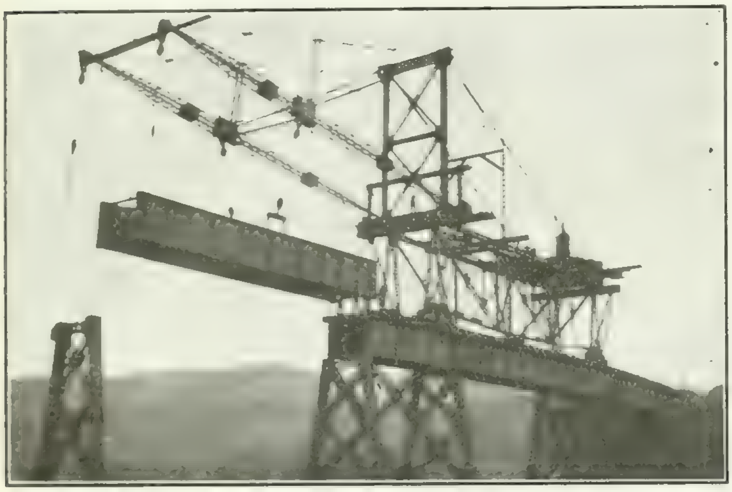
In the meantime track laying had progressed on the north end, the gap being closed about the middle of June, 1912. The slow progress made in track laying is due principally to the excessive amount of bridging and trestling on this line. Between the "Soo" and Josephine Junction there is about 16,000,000 ft. B. M. of bridge timber in 140 structures, besides 100,000 lineal feet of piling. Some of these bridges are very large, and as all the bridge timber used, excepting a few thousand feet cut in the country, is British Columbia fir, it is necessary to build these bridges from the end of steel.

The old line from Sault Ste. Marie to Hawk Lake Junction is through a most difficult country to build in, and while the location secured was good on the whole, the line is badly handicapped with heavy grades and sharp curvature. To improve this grade and alinement would require extensive relocating, which for the present is not contemplated. The route, however, is very picturesque and travelers have a treat in rugged scenery awaiting them on the opening for traffic of the Algoma Central north of the "Soo."

While the above work was progressing south of Hobon, a location was made north to the Transcontinental Railway at the new town of Hearst (or Grant) the first division point west of Cochrane, 101 miles north of the Canadian Pacific. This location is on the same grades and curvature as that of the Hawk Lake-Hobon section, viz., 0.6 per cent. compensated grade and 6 deg. maximum curves. Louis Whitman, locating engineer, had charge of the locating with Sanford Hazelwood and W. H. Wilkie in charge of the parties The route traversed by this line is through rough country for 30 miles north of the Canadian Pacific, but north of this the line enters the great clay belt of northern Ontario, and the grading work is light. The south 30 miles, however, bring up the average cost of this line to about $30,000 per mile, including track and structures.

The crossings of the Canadian Pacific and the Canadian Northern Ontario extension (under construction) are made at grade. There are very few bridges on this 100 miles, and none at all of any size excepting a bay crossing of Oba Lake, where four pile trestles were driven, one of them being 1,302 ft. long, with deck 10 ft. above the water. The balance of the bridging consists of pile structures, the largest being the crossing of the Mattawishquia River, 700 ft. long, near Hearst at the junction with the National Transcontinental. The grading quantities on this 100 miles will be, approximately, 360,000 cu. yds. solid rock, 250,000 cu. yds. loose rock, 1,500,000 common excavation, and 3,500,000 cu. yds. overhaul. About 80,000 lineal feet of piling and 1,500,000 ft. B. M. bridge timber are required. Corrugated ingot iron pipe is used principally for culverts, there being a few of native timber, but none of concrete. In August, 1911, a contract was let to the Superior Construction Company, Sudbury, Ont., for the construction of this section complete, including grading, bridging, track laying and ballasting. The grading is more than 60 per cent. completed, and track laying was started about June 15th, at Hobon. It is expected to reach the Canadian Northern crossing in October, thus placing the Algoma Central in a position to deliver construction material and supplies to the contractors for this line at Oba.

Explorations for extensions of the Algoma Central & Hudson Bay north of the National Transcontinental have been made. A copper metallic circuit telephone line has been constructed from Sault Ste. Marie, through to Michipicoten Harbor and extension to the mines and north to Hobon and Hearst will be made this summer.



Construction of Montreal Viaduct.

At Sault Ste. Marie, new terminals, consisting of a modern engine house, machine shop, store and office building and a new terminal station and office building are all contracted for and the work started. This work involves the expenditure of about $500,000, and includes an extension of the main line to reach nearer the centre of the city of Sault Ste. Marie. A new yard will be built at Tagona, the industrial centre, where extensive alterations and additions to the terminal facilities are being made. The company will also build a large coal and ore dock at Michipicoten Harbor in the near future.

The Algoma Eastern.—The original charter for the 85 miles of this railway now being completed from Sudbury to Little Current on the Manitoulin Island, was obtained by F. H. Clergue at about the same time the Algoma Central project was launched. As in the case of the latter road a land [illegible] of the charter. Actual construction of the line was delayed from year to year, after the first section of 13 miles, extending from Sudbury to Gertrude Mine, was constructed in 1900-1901. An extension of [illegible] connection was made with a spur track connecting with the Canadian Pacific at Victoria Mine station. This spur, three [illegible] per Cliff.

[illegible]

A party, in charge of Louis Whitman, locating engineer, was started at Little Current on a route over which the writer had run a line for the old Sault Company in 1900. This line traversed the islands and skirted the shore of the north channel to the mainland at the mouth of the Whitefish River where it cut through a range of high rock hills facing the lake, thence to a connection with the Canadian Pacific at a point on the Spanish River called Espanola. A section of 1½ miles of this original surveyed line was constructed in 1901 connecting the Spanish River Pulp & Paper Company's plant on the Spanish River with the Canadian Pacific Sault branch. This little section of spur was constructed by the Sault Company and turned over to the Canadian Pacific to operate, under an agreement contemplating the ultimate completion of the whole project.

When the writer took charge of the work, a location was pushed through to connect with the Sudbury end at Crean Hill, a distance of 62 miles from Little Current line with a maximum 1.25 per cent. compensated grade and maximum 11 deg. curves (with a 12 deg. curve near Whitefish) was secured at a cost of about $32,000 per mile complete including track, ballast and building. In July, 1910, a contract was let to the O'Boyle Bros. Construction Company for building the 20-mile section from Little Current to the main shore at Whitefish, and in March, 1911, another contract was let to the Superior Construction Company for the balance of the work from Whitefish to Crean Hill, 42 miles. The grading work on this 62 miles is practically complete and track laying has just been started at Espanola. The 62 miles of track will be laid and ballasted about October 30th, next.

The country traversed by this railway is almost wholly unsettled and south of Espanola is very rugged. From the Whitefish River to Little Current the scenery is most picturesque as the line here follows close to the water and winds around the headlands and bays of that section of the North Channel known as the Bay of Islands. The grading on this section, while practically all solid rock, was not excessive in cost, averaging about $20,000 per mile, including bridging. From Espanola easterly to the junction with the old line at Crean [illegible] country, but, from an agricultural point of view, of little value.

End of Steel A. E. Ry., May 22nd, 1912.

An under crossing of the Canadian Pacific Sault branch is obtained near the village of Nairn Centre, the Canadian Pacific tracks being carried over the Algoma Eastern on a 27 ft. 7 in. skewed deck plate girder span on concrete wing abutments. The bridging on the entire line from Sudbury to Little Current is light for such a country. The steel structures consist of one 105 ft. and one 60 ft. deck plate girder span on stone abutments and centre pier at the Vermillion River crossing, 17 miles west of Sudbury, one 180 ft. through riveted truss span at the Spanish River crossing, mile 42, one 176 ft. through riveted truss span at the second crossing of the Spanish River at Espanola (built in 1901) and two 100 ft. girder spans at two other points together with a 36 ft. deck girder span on concrete at an overhead crossing of the government trunk road near Espanola. These major structures are supplemented by a number of timber trestles and pile bridges. At Little Current, in order to cross the channel, in front of the town, through which there is considerable vessel traffic, a bridge, some 600 ft. long with a draw span is required. This structure will be erected this year.

View of Roadbed at Mileage 87, S. C. & H. B. Ry.

The traffic expected for this railway consists of ore, pulp and paper, coal and the products of the Manitoulin Island, which previous to the construction of this line, was entirely dependent on water communication with the main land. This island is 90 miles long averaging 8 to 12 miles wide, and is capable of great development. The population at present is about 20,000 and at least one-half of the island is fine agricultural land, particularly adapted to hay and stock raising. The construction of the Algoma Eastern formerly known as the Manitoulin & North Shore Railway has been most eagerly looked forward to for years by the Manitoulin Islanders.

The above work has all been in charge of the writer, as chief engineer of both roads. On the Algoma Central & Hudson Bay G. F. Horsey and C. Le B. Miles are in charge of the work at the north end, and L. C. Maxwell and J. A. Hedgecock at the south end as division engineers. B. E. Barnhill is division engineer of the Algoma Eastern with headquarters at Sudbury. W. C. Franz is general manager and G. A. Montgomery superintendent of both roads.

◆

ANOTHER ACCIDENT ON WELLAND CANAL.

Navigation in the Welland Canal is tied up as the result of an accident at lock 23, near Thorold, at 11.30 a.m. August 2nd, when the steamer Wiley M. Egan, bound light from Deseronto to Ashtabula, crashed into the lock and carried away all four gates. Water from the upper levels rushed through the narrow enclosure into the lower level of lock 22, carrying the boat back some distance.

New gates were sent from Port Dalhousie, and Superintendent Sullivan notified, but the placing of them will take some time. The loss is estimated at about $8,000.

PORT ARTHUR WATER SUPPLY.

The city of Port Arthur and Fort William in experiencing the growth and development which has been their lot during the past few years have at last had to face the problem of an abundant supply of pure water for drinking and domestic purposes. The supply of these centres has for many years been Lake Superior, and with the intake many thousands of feet from the shore this source left nothing to be desired, until the industries, many of which located along the water front began to pollute the water front with their discharged refuse; when this pollution reached the proximity of the intake, the matter took on such a serious aspect that the corporation council requested Mr. T. Aird Murray of Toronto to make a report on a possible future supply from certain sources north of the cities, and generally known as Hazelwood Lake and Current River; if this were not practical to make such recommendations as would give the citizens a clean and efficient service for considerable time to come.

In addition to the fact that the water on the land side of the municipalities was practically free from pathogenic bacteria and organisms, this source commended itself on account of the possibility of drawing the supply to the taps by gravity and thus reducing pumpage expenses.

That it is entirely feasible to obtain an abundant supply of water from the Current River at a static head requisite for city purposes, has been demonstrated by surveys and levels. At a point immediately above the Cascades a level of water may be obtained about 400 feet above the level of Lake Superior. This is practically the nearest point from which water can be diverted by a gravity system and the relative costs and efficiencies between a gravity and lake supply are based upon water being diverted from the river immediately above the Cascades.

In order to make a favorable comparison between the two systems it is necessary to assume an equal volume of supply by both gravity and pumping. In the preparation of the report Mr. Murray assumed that the quantity made available be 10,000,000 gallons per day, equal to a per capita supply of 100 gallons for a population of 100,000.

The feasibility of obtaining a supply from Hazelwood Lake was discarded after an investigation, owing to the boggy nature of the water shed and the increased distance from the cities which necessitated additional outlay for pipe, etc.

Chemically and characteristically, the water in Lake Hazelwood, in Hazelwood Creek near the junction at Current River, and in the Current River itself are the same for all purposes.

It is reported that, before the natural level of Hazelwood Lake was raised and flooded lands added, that the water was clear instead of bog colored as at present. At the present time the bog coloring matter both in Hazelwood Creek and in the Current River, is extremely high and for all practical purposes, may be taken as similar in content. So high was the color of this water that the different phases of the chemical analyses of the same, depending on the color of the reagents and precipitates, was rendered extremely difficult and to this fact the slight variations in the table of analysis is due. In the tabulation of the ammonias, this, of course, does not hold, for the water is distilled at as constant a temperature as possible before the reagent is added to compare the tint.

It is possible that if the flood land was scraped and al brush, weeds, tree stumps and soil to a depth of at least one foot were removed that the original clear color might be recovered.

The drainage area of Hazelwood Lake is about 24 square miles and the lake itself about 1,875 square miles, and it is at once seen that this would involve an immense amount of work and an expenditure of about $201,666. That this water ever was sufficiently clear to allow of its use as a domestic supply is based upon hearsay evidence, and that the removal of the organic soil and vegetation will effect the removal of the present bog coloring matter sufficiently to render it suitable for domestic supply without artificial treatment, is problematical.

The question, however, of a gravity supply from Current River deserves serious consideration as the water may be conveyed from a point much nearer the city and the quantity available is ample for all future city requirements.

The waters of the Current River watershed appear to be free from sewage contamination, but reference to the chemical analysis proves this water to be heavily charged with organic matter. The oxygen consumed averages 19 parts in million. The water is very soft, averaging 53 parts in one million, equal to 3.71 grains of hardness to the gallon. The total alkalinity of the Current River waters is low, being 25 parts in one million; and the alkalinity of Hazelwood Lake and Creek is still lower, being 18.5 parts in one million. The amount of vegetable dye or peaty coloring matter in this water is also extremely high and shows a color content of 156 parts per million on the platinum cobalt scale. Generally speaking the water is fit for human consumption but owing to the coloring matter it is extremely objectionable.

The examination of the waters was made in the early spring, and it must be anticipated that the vegetable content will prove much more objectionable in the autumn when the process of decay sets in.

The coloring matter is in almost perfect solution, and cannot be removed by filtration alone, but can be removed by a combined method of filtration and coagulation. It has been shown that to remove 57 per cent. of the coloring matter, leaving a color content of 67 parts per million, will require the use of 3 grains of alumina sulphate per gallon and 7/10ths of a grain of soda ash. No data is to hand of such large quantities of coagulant being necessary elsewhere. The color of this water is extremely difficult of coagulation, owing to the low alkalinity of the water, as water required a pronounced alkaline base in order to set up the necessary [illegible]

ITEMS INCLUDED IN COST OF GRAVITY SCHEME TO PROVIDE 10,000,000 GALLONS PER DAY FROM CURRENT RIVER.

Head works and dam	$ [illegible]
[illegible]	[illegible]
Filtration plant and coagulation basin ..	120,000.00
Duplicate 24-inch mains, head works to [illegible]	[illegible]
Single 24-inch main, reservoir to River [illegible]	[illegible]
[illegible]	[illegible]
[illegible] Street, Balsam and Van Norman ...	20,205.00
[illegible]	[illegible]
	[illegible]
[illegible]	[illegible]
	[illegible]

The cost of sodium carbonate and sulphate of alumina in this country is very high as it is not manufactured in this country and is, therefore, subject to duty. Calculations of the cost of sulphate of alumina and soda ash delivered at Port Arthur show that the cost of coagulants at the above ratio of treatment amount to $9.30 per one million gallons decolored, and that if 97 per cent. of the color be removed the cost is $22.08 per one million gallons of water decolored. Apart from this cost there must be considered the cost of cartage from the rail cars to the treatment works and the expense of filtering.

It will be readily seen that owing to the density of the coloring matter and the low alkalinity of the Current River waters, that the removal of this color is its chief objection to its availability. Although the color is less in Hazelwood Lake and Creek than in the main stream, the alkalinity is lower and the cost of treatment is much the same, there being required a greater proportion of soda ash than alum.

Items included in cost of pumping scheme to provide 10,000,000 gallons of water from Lake Superior, with an intake at city limits:

Duplicate 24-inch water pipe	$ 55,000.00
24-inch mains	350,000.00
12-inch mains	26,264.00
Pumphouse	8,000.00
Pumps	24,000.00
Removing old pumps	3,000.00
New well	4,500.00
Two houses	7,000.00
	$477,764.00
Deduct cost of pumps not required at present	12,000.00
	$465,764.00
Add 10 per cent. for contingencies, supervision, etc.	46,576.00
	$512,340.00

In order to compare the relative cost and efficiency of a gravity supply with a pumping supply, it is necessary to estimate the cost of a pumping supply delivering from a point at the city limits 10,000,000 gallons of water per day to the city. And a plan has been prepared which shows the layout of a force main system, designed to deliver 10,000,000 gallons of water per day. It is suggested that duplicate steel intake pipes be laid into about 41 feet of water 2,500 feet in length, working under a static head of 15 feet [illegible] inches. Each of the pipes will be capable of delivering to the pump well approximately 8,000,000 gallons per day, or a total delivery of 16,000,000. The suggestion, as far as a steel pipe is concerned, is only tentative, as no borings have been made at this point to prove the class of strata. If solid rock, which is probable, it will be as economical and more efficient, to construct a tunnel.

Duplicate lines of [illegible]-inch force main are shown from the pumphouse to the corner of Algoma and McDougall Streets. In former reports [illegible] mains were suggested, but [illegible] supply than [illegible] per day.

Under a [illegible] gallons per day supply, [illegible] the energy required to raise the water from the pumphouse to McDougall and Algoma [illegible]. If the pipes be [illegible] diameter then the energy required [illegible] pounds to [illegible].

COST OF INSTALLING PUMPING SUPPLY FROM CITY LIMITS AND 24-INCH DUPLICATE FORCE MAINS IN ORDER TO SUPPLY 10,000,000 GALLONS PER DAY, IN ACCORDANCE WITH PLAN, $512,340.

Operating Cost.

To pump 10,000,000 gallons per day for low level supply requires 953 H.P., and for high level supply 238 H.P. Total horsepower, 1,191.

Above is for a head of 500 feet, assuming that low and high level is half this amount, or 250 feet head in each level.

*1,191 H.P. at $15	$17,865.00
Operating for 365 days at $10	3,650.00
Incidental expenses per annum	500.00
Annual operating expenses	22,015.00
$22,015.00 capitalized at 5 per cent. equals a capital amount of	440,300.00
Total capitalized cost of pumping scheme from city limits, delivering 10,000,000 gallons per day	952,640.00

***Note.**—Power costs fifteen dollars per H.P. when consumption reaches 10,000,000 gallons.

Capitalized Cost of Gravity and Pumping Supplies Compared.

With 57 per cent. of the color removed:—	
Current River scheme	$1,432,819.00
Pumping scheme	952,640.00
Balance in favor of pumping	$ 480,179.00
With 97 per cent. of the color removed:—	
Current River scheme	$1,861,500.00
Pumping scheme	952,640.00
Balance in favor of pumping	$ 908,860.00
With no color removed:—	
Current River scheme	$ 644,319.00
Pumping scheme	952,640.00
Balance in favor of gravity scheme	$ 308,321.00
Cost of gravity scheme apart from operating expenses	$ 600,619.00
Cost of pumping scheme apart from operating expenses	512,340.00
Balance in favor of pumping	$ 88,279.00
Cost of gravity scheme, capitalized operating expenses only	$ 832,200.00
Cost of pumping, operating expenses only	440,300.00
Balance in favor of pumping	$ 391,900.00

The question has been raised as to what effect the choice of either of the above alternative systems may have upon the problem of the disposal of the city sewage.

At present the sewage of both Fort William and Port Arthur is discharged in a raw state into Thunder Bay. It has been felt that any decision to rely upon Thunder Bay water for purposes of domestic supply will entail the necessity, in the near future, of a large expenditure in trunk sewers and efficient disposal works for the purification of the sewage before it enters the bay. Fort William has a supply of water by gravity independent of the bay water, and it has been suggested that if Port Arthur could also obtain a similar source of supply, then the necessity for sewage disposal will cease to exist.

The real question to be asked is: Apart from any law of the land prohibiting the discharge of raw sewage into fresh water, will the citizens themselves be content to turn their harbor into a cesspool and sewage disposal area? Apart from the question as to any effect such a discharge of sewage may have upon the domestic water supply, is it not possible and very probable that as the Twin Cities grow in population and the amount of raw sewage increases and the effect upon surrounding waters becomes apparent to the senses, that the citizens will demand that the nuisance be removed.

The history of the pollution of Toronto harbor and the demand by the people that an apparent nuisance be removed by the construction of trunk sewers and disposal works, is an illustration to hand.

In Toronto there has recently been installed an up-to-date filtration plant to remove turbidity and bacteria from the water; also there has been constructed trunk sewers and sewage disposal works, not with the object of removing disease infection from the sewage and safeguarding the water supply, but simply for the purpose of removing from the bay what has been considered a nuisance and disgraceful condition in Toronto harbor.

With similar increase in population, conditions will gradually assume just as objectionable features at Port Arthur and Fort William as at Toronto.

Apart from the actual water consumed from the tap, there is also a summer floating population to be considered, which will at times consume the water direct from the bay.

The question of sewage disposal has not been gone into in any detail, but it is considered that when this problem is taken up, that a trunk sewer system should be constructed from north to south, with disposal works located west of the Canadian Pacific Railway, and north of the McIntyre River. The area suggested is hatched with black lines on Plan B.

Conclusions of the Report.—That owing to the density of color matter in the Current River and its branches, that this watershed does not present a character of water which can economically be presented as an efficient domestic supply to the city.

That a pumping supply be installed at the north city limits.

That duplicate 24-inch intakes be installed.

That the pumping units at the new pump-house consist of the present turbine pump, and a new 2,000 gallons a minute turbine pump.

That the routes for the new 24-inch duplicate force mains be adopted.

That the present water wheel driven pump be maintained at the present pump-house as an auxiliary supply.

That hypochlorite treatment apparatus be installed for use only when required.

The estimated cost of construction of scheme is $512,340.

◆

NEW GRAIN ELEVATOR FOR WEST ST. JOHN, N.B.

The Canadian Pacific Railway have recently concluded arrangements for the construction of a one-million bushel grain elevator at the above-mentioned point.

The elevator will be of reinforced concrete. It will be capable of unloading 160 cars in 10 hours, and of shipping to ocean vessels at several different berths. The elevator will be electrically-driven, a power plant for the generation of electric power being included in the contract. An extensive shipping gallery system will also be a part of the work. The elevator is to be ready for the winter shipping season of 1913 to 1914.

The approximate cost of this work is $500,000, and the John S. Metcalf Company, Limited, of Montreal, have been awarded the contract to erect the structure.

ALUMINUM OVERHEAD CONDUCTORS.

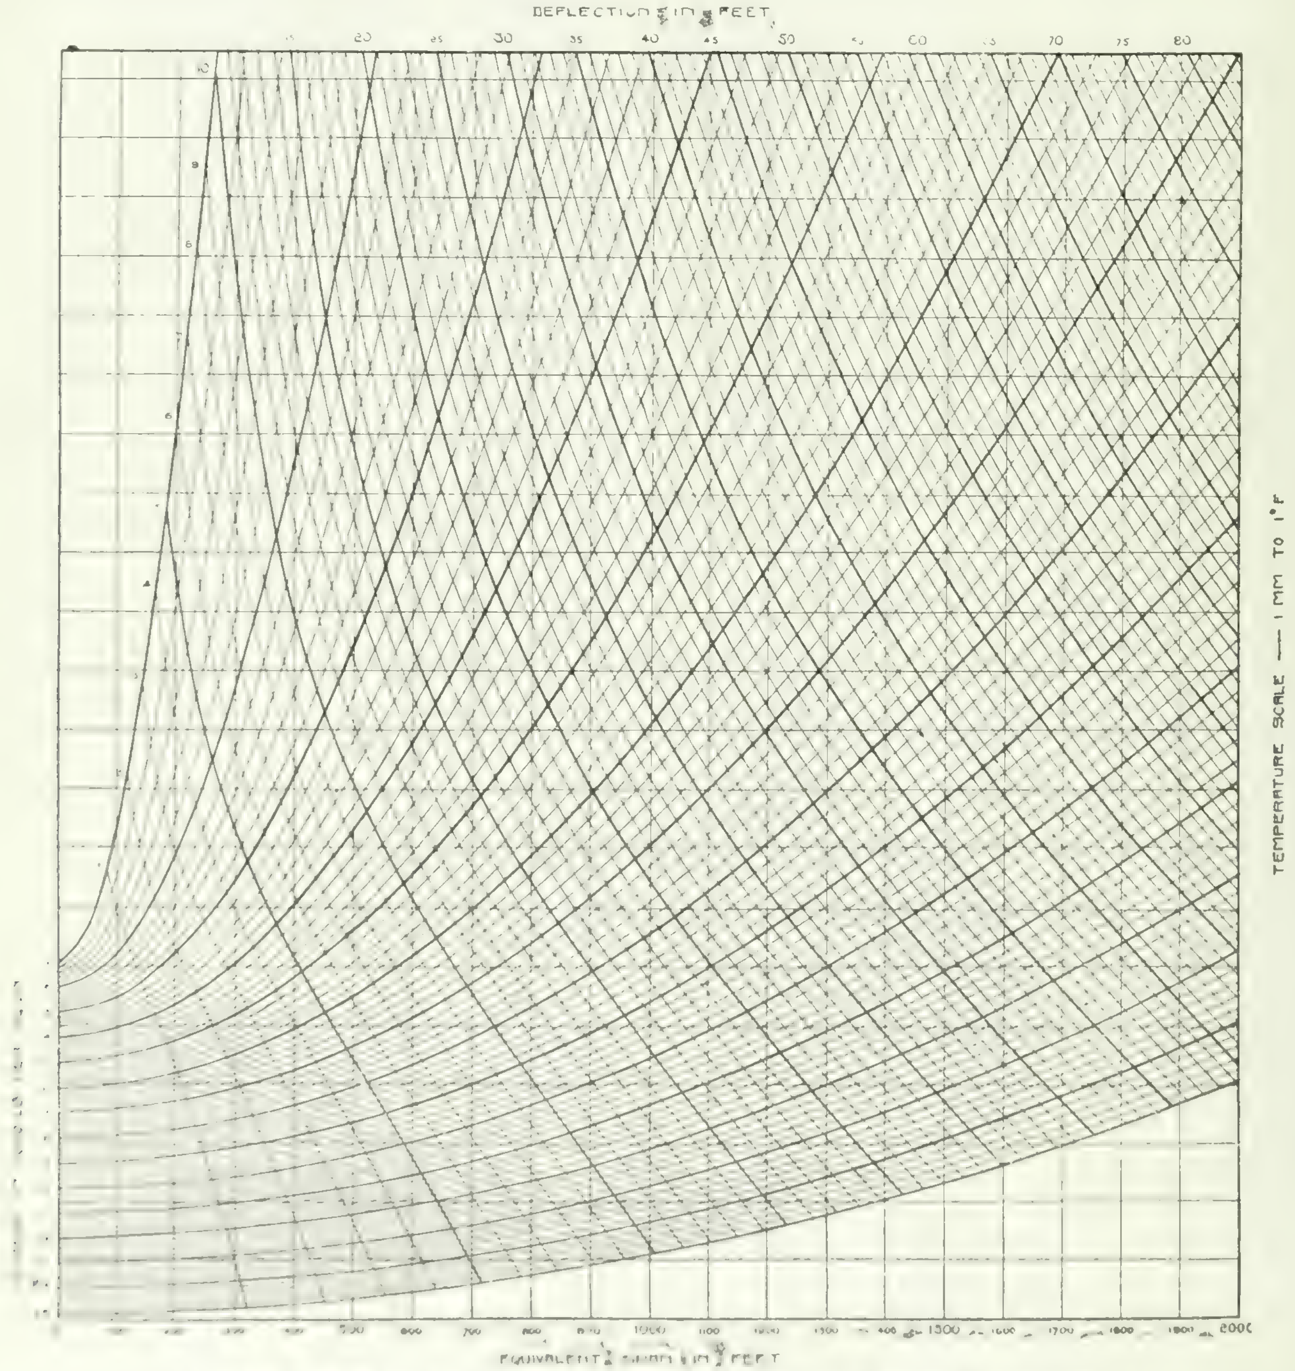
The accompanying chart has been developed by the British Aluminum Company, Limited, of 109 Queen Victoria Street, E.C., for the purpose of determining the deflection and stress in overhead conductors of aluminum. The Electrical Review received permission to reproduce the chart, of which the company retains the copyright. As the use of metal is increasing, we present the matter herewith to our readers.

The company claims that this is the first logically correct means of determining the physical characteristics of aluminum conductors that has yet been placed in this country, and it would take the place of the calculations, often [illegible] approximations, which have hitherto been used. Information not found on the chart will be readily supplied by the company; a useful and complete comparison between copper and aluminum conductors will also be found in the article by Mr. E. V. Pannell, which was published in *The Canadian Engineer* issue of July 18th, 1912.

It is important to note that the chart as here reproduced is reduced in the ratio 5:2; the temperature scale is therefore modified, and each division represents 20 mm., or 20 deg. Fahr.

1. At constant temperature the intercept of the ordinate of the span with the curve of required stress will give the corresponding deflection; e.g., span 700 ft., stress 10,000 lb. per sq. in. Deflection 7.2 ft.

2. To allow for a rise of temperature follow the ordinate vertically upwards (1 mm. to 1° Fahr.); e.g., as above, allowing for a rise of 50° Fahr. Deflection 11.8 ft., stress 6,100 lb. per sq. in.



Universal Stress-Deflection Chart for Standard Aluminum Overhead Conductors.
Based Upon the Laws of the Elastic Catenary.

Modulus of Elasticity [illegible] lb. per sq. in. Coefficient of linear expansion [illegible] per 1° Fahr. Weight per sq. in. per ft. run 1.175 lb.

3. Again, as example 1, but taking into account a wind pressure of 30 lb. per sq. ft. on a conductor of 0.6 sq. in., the stress to be as before, multiply the span by the appropriate value of "q" given below, i.e., 700 × 2.33 = 1,631. Proceed as before, but divide the deflection so obtained by "q," i.e., 39/2.33 = 16.7 ft.

4. The deflection on the line in still air will be found by following the horizontal line through the point just determined until it intercepts the ordinate corresponding to the true span of 700 ft., giving a deflection of 13.6 ft., and a stress of 5,300 lb. per sq. in.

The value of "q" is the ratio of the total loading per ft. run to the weight of conductor per ft. run. Thus, if "w" be the weight and "p" be the effective wind pressure per ft. run of projected area (reduction factor 0.6) then $q = \sqrt{w^2} + p^2/w$.

Cross-section of conductor, sq. in.		0.1	0.2	0.4	0.6	0.8	1.0	1.2	1.4	1.6
Value of "q" with wind pressure of	30 lb. per sq. ft.	5.21	3.48	2.77	2.33	2.08	1.92	1.79	1.71	1.64
	20 lb. per sq. ft.	3.58	2.61	1.99	1.72	1.57	1.48	1.41	1.36	1.32

FIRST REPORT OF MONTREAL TRAMWAYS COMPANY

The first comprehensive report of the Montreal Tramways Company has just been compiled. The appearance of this report has been awaited with interest, the reason being the many changes which have taken place in connection with the affairs of the company during the past year. It is only two years since the present management assumed control of the street railway. It was not until about a year ago that, in the reorganization, the Montreal Tramways Company took the place of the Montreal Street Railway Company. Many changes have been effected during the year, among these being the formation of the holding company known as the Tramways and Power Company, through the medium of which the desired object of the present control was brought about—namely, the joining up of the street railway interests with those of the Canadian Light and Power Company.

The common stock of the Tramways Company, which company succeeded the Street Railway Company in all its rights, franchises and privileges, was in the nature of a bonus stock to accelerate the exchange of street railway shares on the basis of the offer made public at the time. The public was unwilling to commit itself to any very definite views regarding the value of the tramways common stock, some claiming that it was too much of the nature of water to be of much value, and others assuming that its value was somewhere in the vicinity of $30 to $35 per share. Of late this stock has been advancing constantly and recently it reached par. This week buyers were asking 110 for it.

Difficult as it has been to place any specific value on Tramways Common, the work of valuing Tramways and Power has been much more difficult, inasmuch as the latter company is a holding company into which go the surplus earnings on the stock of both the Tramways Company and the Canadian Light and Power, so that it becomes necessary to know somewhat of the earnings of both companies before the value of Tramways and Power can even be approximated. The stock has been experiencing a somewhat interesting movement of late and prices advanced to 60, later declining again to slightly above 50.

The financial report just issued shows that the company has made progress since the last annual report. The result of the nine months makes a good showing as compared even with the entire previous twelve months, as the following will show:—

	9 Months, 1912.	12 Months, 1911.
Gross earnings	$ 4,355,403	$ 4,775,300
Op. expenses	2,618,943	2,679,805
Exp. p.c. of earnings	60.13	56.12
Net earnings	1,736,549	2,095,080
Pass. carried	104,458,960	118,268,080
Car earnings per passenger	4.06	3.94
Transfers	34,947,315	40,488,545
Total pass. carried	139,406,275	158,756,625
Car earnings per pass. total carried	3.04	2.93

It will be observed that the car earnings per passenger shows a considerable increase. This is not surprising to Montrealers who have been raising objections to the overcrowding of cars. It is estimated that on the basis of passengers carried there should be an increase of 27,000,000 in passengers for the full year. The total carried last year was somewhat less than 159,000,000, while during the nine months period, according to report, somewhat less than 140,000,000 passengers were carried, making about 186,000,000 passengers per year.

It is also worthy of comment that the earnings for the nine months of this year are in excess of those for the full year ending September 30th, 1910, as well as for all full years previous thereto. The financial report for the nine months ending June 30th will, it is understood, be presented at the annual meeting on August the 6th and is as follows:—

Gross earnings		$4,355,403.57
Operating expenses		2,618,943.65
Net earnings		$1,736,459.92
From which deduct:—		
City percentage on earnings	$279,030.17	
Interest bonds and loans	449,513.67	
Interest debenture stock	600,000.00	
Taxes	50,850.00	
		1,379,393.84
Surplus		$ 357,066.08
From which has been appropriated for:—		
Contingent account		150,000.00
Transferred to general surplus		$ 207,066.08

No statement has heretofore been made of the number of shares of street railway which have actually been turned in for exchange. While President Robert in his report does not mention the actual number still outstanding, he states that only a few shares have not been exchanged. Reference is also made to negotiations in progress between the city and the railway for the purpose of securing a new contract.

The recent general manager, Mr. Duncan McDonald, has been succeeded by Mr. James E. Hutcheson, former superintendent of the Ottawa Street Railway, who has already taken up his work. It is understood that other changes will take place on the staff shortly.

FUEL OIL FOR SHIPPING

Officials of oil companies have learned that the Canadian Customs Department will probably decide to admit fuel oil for shipping use free of duty to Canada. Since July 12, when a tank steamer with a cargo of fuel oil for shipping use reached Vancouver from San Francisco, and a duty of 2½c. a gallon was demanded, the companies engaged in the fuel oil trade have been awaiting a decision by the Minister of Customs on an appeal taken as a result of this duty. Many of the trans-Pacific steamers of the Canadian Pacific and Grand Trunk railroads use fuel oil, and the imposition of such a duty would mean a doubling in the price of the product of these and other companies operating oil-burning ships.

Within the last seven years, according to oil authorities, practically all the local steamers at Vancouver and on Puget Sound have been converted into oil burners, while to-day a large majority of the larger off-shore liners are burning fuel oil. The saving in space and operating expenses has appealed to owners, and with the improvement in atomizing the fuel, its use has become much more satisfactory. Many manufacturing plants also have discarded coal for oil, and this ever-growing market has brought the importations of oil to Vancouver and vicinity to unexpected proportions.

Hon. Winston Churchill, the First Lord of the British Admiralty, recently announced that an investigation into oil fuel would be made. Oil burning engines are going to play an important part in many of the new crafts that are now being built and those in contemplation in the principal shipyards of the United States and England. According to a well-informed marine builder, there are no less than 242 steamers fitted for burning liquid fuel, the largest being the Toyo Kisen Kaisha liner's Tenyo Maru and Chiyo Maru of 13,454 tons gross and 13,431 tons gross respectively. In this connection it is of interest to note that the new Cunard liner Aquitania of 50,000 tons gross in the course of construction on the Clyde is to be similarly equipped, while the White Star boat of 18,000 tons which is now being built at Belfast for the Cape-Australian routes, and which is to be named the Ceramic is also to use oil. Quite a large number of the oil burners are now employed in the Pacific, two of them the Ventura and Sonoma recently inaugurated a service for the Ocean Steamship Company between San Francisco and Sydney, New South Wales. Another line of steamers burning oil fuel, the Crown Line, will soon be running between Pacific Coast ports and Australia.

The Colonial Transportation Company of Mexico is equipping its barges with oil engines and the use of oil for fuel promises to supersede other fuel upon nearly all the river and coastwise vessels on the east coast of Mexico. There is [illegible] for fuel by manufacturing plants in various parts of Canada and the United States.

Since the British coal strike in the early part of this year [illegible]

[illegible]

makers that many English firms are, as a result of the late strike, seriously considering the advantages of motor transport. Commercial travellers are using motor-cycles in increasing numbers when calling upon their customers, as they can travel, it is stated, a hundred miles upon a gallon of petrol (gasoline) and carry their samples, unless they are of great bulk, be entirely independent of the railways and be able to call upon a greater number of people than they possibly could if restricted to steam travel.

◆

DISTRICT HEATING BUSINESS.*

By A. D. Spencer.

The district heating business is nearly as old as the electric lighting business. As early as 1890 a number of electric lighting companies were selling exhaust steam for heating purposes. At the present time there are over 300 heating plants in the United States. The National Electric Light Association committee gives answers from 100 companies, one-half considering the business directly profitable, while practically all agree that it is of great advantage in connection with electric supply.

While the value of a combination electric and heating system is being recognized more fully as the companies extend their field to include the large commercial establishments formerly considered out of the reach of the central station, it is impossible to find another business so well established and in which so many companies are engaged where one-half believes that the business is yielding no profit.

It is doubtful if a majority of heating companies have the necessary data to make up a reliable operating balance. Heating plants are outgrowths of the electric business and generally are operated in connection with it; therefore, the expenses frequently are not separated. The heating revenue is credited to the fuel account and often assumed to be practically all profit; a cost analysis is considered unnecessary. Where an analysis is made, it is many times inadequate, the general expenses, fixed charges and depreciation being omitted.

Failure to show profit may be due to inadequate rates. Many managers consider heating revenue practically all net gain and they establish schedules without considering the value of the service to the consumer or of its cost to the company. The popularity of the service shows conclusively its value.

The value to the consumer is easily from 10 to 25 per cent. more than the cost of maintaining his own plant, due to the absence of smoke and dust, to lower insurance rates, to the release of valuable space otherwise occupied by the plant, and to the greater convenience and reliability of the district heating service. The value of the service will generally permit rates based on the cost of supplying live steam, and rates should always be so based, rather than on the not always correct assumption that the steam is a byproduct.

Faulty construction or improper operation may cause a financial loss. The same care should be exercised in designing and constructing a heating system as in the electric-supply system. In general, the distribution system should [illegible] density of business with the minimum length of mains. The load on existing mains should be increased and extensions made only where it is certain profitable business can be obtained.

---

*[illegible] District Heating Association, at [illegible]

Customers' installations should be subject to supervision. Where flat rates are in use, rigid regulations should be enforced, underground construction should be of best quality to reduce maintenance costs and minimize heat losses. But it must be kept in mind that investment charges on expensive underground construction form a serious item in the cost of district heat supply, and construction costs must not become so heavy that the charges more than offset the resulting operating economies. Where meters are used, a thorough system of inspection and tests is necessary to prevent serious losses of revenue. Above all, adequate records are essential for intelligent and economical operation.

Local conditions have much to do with the success or failure of heating systems; and plants are operated in many places where local conditions do not warrant the investment. This is partly due to the idea that any heating revenue is net profit, and to considerations of policy, such as necessity for occupying the territory to prevent undesirable competition and the ability to offer heating service in connection with electric service. Among the points to be considered in local conditions are location of steam plant, density of available business, probable growth of district, obstructions to underground construction, probable loss of electric-plant capacity and efficiency due to back pressure, length and character of heating season, probable coördination of heating load and electric loads and relative costs of steam coal and domestic coal. These points apply to exhaust heating. Where live-steam heating is contemplated, other considerations enter and the chances of loss become much greater.

Plants depending principally on electrical business may be operating at a loss because they carry undesirable business, such as restaurants, etc., which require summer service. Low rates may be intentionally established to facilitate taking over private plants, with combined heating and electrical load, but this does not seem warranted except where the value of the service to the consumer will not permit higher rates and where the net result is an advantage to the entire electric business.

DEPRECIATION AND SINKING FUNDS.*

By C. A. Smith, A.C.U.A., Accountant Municipal Tramways Trust, Adelaide.

I have decided to continue the discussion on depreciation and sinking funds as introduced by George Macoun in his paper, which was read before the Australasian Tramway Officers' Association in Sydney on October 9th, 1908.

Mr. Macoun's object was evidently to open up ground for discussion with a view of promoting a better understanding of the subject generally. He quotes the statement of James Dalrymple (manager of the Glasgow Tramways), who, at the Municipal Tramways' Association at Leeds in September, 1906, said: "I have always looked upon municipal corporations very much as I look upon an individual. If I, as an individual, borrow £1,000 to start business, I must pay that £1,000 back before I am a free man," and concludes that he approves of the remark "that a sinking fund has nothing whatever to do with a depreciation fund." Undoubtedly Mr. Dalrymple is right in the latter contention, but his argument that because an individual should pay off his loans the corporation should do the same is not necessarily logical, nor is it incumbent upon the individual to repay his loans, unless, perhaps, with the borrowed capital. Mr. Dalrymple's ideal of a "free man" and "free corporation" is largely a matter of sentiment and will be dealt with in connection with municipal debt and credit later on. Mr. Macoun also says that at the same meeting G. W. Holford, general manager of the Salford Tramways, stated the view that rolling stock, buildings and overhead equipment could be maintained out of revenue, but that a reserve for renewals of permanent way is absolutely necessary. I do not think it advisable to introduce to such an extent different principles in the treatment of different parts of the undertaking, as this destroys to some extent the value of the comparative statements of operating costs. It is clearer and better to keep operating expenses, including ordinary maintenance, distinct from renewals, and separate accounts should be kept for the renewal of each class of plant and machinery, etc., but permanent buildings of an incalculable length of life may be maintained out of revenue.

The rates at which the various tramway undertakings provide for their depreciation reserve are as variable as they are interesting. Especially interesting is the reserve of the Glasgow Tramways, which to-day stands at about 50 per cent. of the capital cost. In the opinion of Mr. Dalrymple, therefore, the Glasgow Tramways have depreciated 50 per cent., notwithstanding their high standard of maintenance and the large sums already expended in renewals. This is referred to as being a very gratifying financial position for the Glasgow corporation; undoubtedly, nevertheless, the reserve may be unwarranted, and I have very grave doubts as to whether the Glasgow corporation values its assets at only half of the capital cost.

Obsolescence.—As Mr. Macoun has pointed out, obsolescence is a quantity as incalculable as an earthquake, and it may happen that in the reserve to cover obsolescence there may be a provision greatly in excess of the requirements of the more modern parts. Whichever way it may occur, in all probability it may only be partial in an electrical tramway system for a great number of years, and a large residual value may remain; but if it is a question of life or death, which we cannot cover by insurance, we must take the risk.

As a matter of course the renewal fund is raised from year to year, and renewals are made during the same periods, so improvements are introduced and obsolescence gradually gives place to modern inventions, and the great "bogey" obsolescence, which has hitherto been more imaginary than real, is no more to be provided for, other than in the renewal fund, than an earthquake.

Depreciation is not provided for generally by state governments, but they pay for their renewals, when convenient, out of the then current year's revenue. Such renewals sometimes include a proportion of capital expenditure left unrecorded as such. This is a system to be deprecated. Ultimately the undertaking may thereby show a greater percentage of revenue to the capital cost recorded in the books, but a government which treats its accounts in prosperous seasons in this manner shows fictitious results and deludes itself and the public, believing that its railways and tramways are subsequently paying, whereas, had the capital expenditure out of revenue been capitalized instead of written off as expended, a loss might have been manifest later. Revenue expenditure is thus imposed upon in prosperous seasons, and the so-called capital cost is kept far below the actual capital outlay.

This system is also to be deprecated because in poor seasons the permanent way and rolling stock become starved, and depreciation then sets in at on increased ratio and there is no provision to meet it. Generally speaking, however, the tendency is to load the capital and let the working cost down too lightly.

---

* Abstract of paper read at third conference of the Australasian Tramway Officers' Association.

A company with keen competition and limited rights is situated very differently from a company with a monopoly and limited rights. Both of these must charge a price sufficient to cover all losses and also sufficient to provide profits with which to pay lucrative dividends. Again, a municipality with a monopoly and an unlimited franchise is situated so favorably that its costs of transport should be unapproached by any other system, being free from competition and the necessity of making profits. But under any system the price of the ticket should be sufficient to create an ample reserve for renewals, as this undoubtedly is required to provide for one of the losses which should be covered in the price paid for the fare, being the extent to which depreciation is estimated to have occurred.

Depreciation.—The subject is very wide because different classes of assets depreciate at different rates, but as a matter of principle when capital is spent in the purchase of machinery, plant, land or buildings with a view to a profit being earned, provision must be made for the replacement of the capital before the return can be regarded as profit.

In determining the rate of depreciation the main facts to be kept in view in reference to a particular subject are:

First—The original cost.
Second—The annual repairs required.
Third—The probable life.
Fourth—The market value.
Fifth—The break-up or residual value.

In allowing for depreciation the rate may be calculated on the original value or upon the diminishing value from which the depreciation of previous years has already been written off.

Where the depreciation allowed is on the original cost a much lower rate is sufficient than where the depreciation is calculated on the diminishing value. The usual method is to calculate depreciation on the diminishing values, the effect being that in later years the charges for depreciation are lighter; but this, as a rule, is counterbalanced by the increasing cost of repairs as the assets get older. As an example, if the life of a machine be taken at twelve years with a residual value of 10 per cent. of the prime cost, then depreciation would need to be written off at 7½ per cent. per annum each year. To arrive at the same result, if the percentage is written off the decreasing value each year, it will be necessary to write off at the rate of 17.46 per cent. per annum on the decreasing value; and again in providing a reserve for renewals to be invested at compound interest at current rates pending the amortization of the plant, a still lower percentage may be taken, shown as follows: £100 in twelve years on diminishing values, with a residual value of £10, equals 17.46 per cent. per annum; £100 in twelve years on original cost, with a residual value of £10, equals 7.50 per cent. per annum; £100 in twelve years invested at 3½ per cent. interest, with a residual value of £10, requires a reserve of 6.16 per cent. per annum.

The latter system of providing and investing the reserve is preferable, as the annual charge is regular and lower than [illegible] and there is provision available to carry out the renewals as they become necessary.

Reserve for Renewals and Sinking Fund.—The reserve for renewals should stand entirely upon its own foundation and not be associated with the requirements of a sinking fund which may exist for distinctly different purposes.

The object of the reserve for renewals is to replace worn-out assets. The object of the sinking fund is to accumulate capital for the purpose of paying back borrowed capital.

The reserve for renewals and the sinking fund may be [illegible]

In determining the reserve for renewals we take into consideration the amortization of the plant and provide for its continuance, or, in other words, we keep up the value of the capital, either in plant or investments, and base its upkeep on its life.

In determining the sinking fund, should we not also consider the amortization of the community, which is responsible for paying off the loan, or whether the community may be considered at all to amortize? In the former case the machinery and plant will, we know, be entirely renewed in a given number of years, and the community using that machinery and plant will be obliged morally and economically to pay the cost; but having done that, the community, as a community, continues as juvenescent during the period of the depreciation and renewal of the whole undertaking. Also, as a sinking fund is the accumulated wealth of a continuing community, the question is, how far will the present generation participate in the advantages of the sinking fund? and just to this extent should they contribute toward it in the price they pay for their tram fare. It is not a simple proposition that if the life of a generation is forty years one-fortieth should be paid off yearly; but the proposition is this—provided that obsolescence is not contemplated, at what rate should a continuing, ever-juvenescent and increasing community accumulate capital in the form of a sinking fund, or is there any moral obligation or economic reason why it should create a sinking fund at all? In forty years, in all probability, owing to the increased population, the debt per head will have been reduced 50 per cent., and with increased land values I consider it quite unnecessary to bestow upon the next generation a system fully equipped and free of cost.

◆

WATERPROOFING CONCRETE.

A method of treating concrete proposed in a report submitted to the National Association of Cement Users, is the following. On flat surfaces lay a base of concrete at least 2 inches thick, and plaster while still wet with ⅛ inch of neat cement, trowelled hard; follow with another layer of finishing concrete not less than 3 inches thick. On wall surfaces, as soon as the timbering has been removed, thoroughly wet the surface, trowel on ⅛ inch of neat cement, and follow with a 1 inch coat of 1 : 2 cement mortar before the neat cement has begun to set appreciably. If the surfaces treated in either way are of large areas, the materials applied should be reinforced to obviate cracking.

◆

TESTS FOR INSULATED WIRE.

A revised set of regulations issued by the Electrical Department of New York City provide that the insulation shall be of rubber or other homogeneous compound which has been approved, and specify a definite thickness for each size of wire. As a protection against too soft an insulation, the rules stipulate certain tests, among which is the following: The braiding is carefully removed from a portion of the sample, and the copper wire is connected with one terminal of an electric circuit, of which a testing tool forms the other terminal. The portion of the sample from which the braiding has been removed is placed on a flat surface, and the tool edge, which is placed across the sample, is pressed down on to the insulating cover with a pressure of 5 lbs. which is maintained for about a quarter of an hour. The electric current, which must be at least 100 volts alternating, is then turned on, and the tool edge must not sink far enough through the insulation to touch the copper wire and complete the electric circuit.

MANUFACTURE OF RAILWAY TIES

Approximately 70% of ties purchased in Canada in 1910 were hewn. It is apparent that methods of manufacture of ties are not undergoing any great general and permanent changes. Sawn ties were 30 per cent. of the total, which is the same proportion as in 1909. The only important species which has a majority of sawn ties is oak, 95 per cent. of which were sawn ties. Cedar ties were 81 per cent. hewn, and 61 per cent. of the jack pine ties were hewn. Hemlock and Douglas fir were about evenly divided in the method of manufacture. In the case of tamarack, 98 per cent. were hewn ties, while the minor varieties were principally sawn ties. The hewn ties are nearly all pole ties, the sawn ties are made chiefly from larger timber.

Sawn ties cost on the average 36 cents per tie. Hewn ties cost 3 cents more, or 39 cents per tie. Oak was the most expensive of sawn ties, costing 74 cents per tie. White pine was the cheapest of the sawn ties, costing only 23 cents per tie. In hewn ties, oak was also the most expensive, costing 68 cents, and spruce ties were the cheapest, costing 25 cents per tie.

The steam railways use 96 per cent. of all the ties. The decrease in use of ties in 1910 is due chiefly to decreased purchase by the steam railways, which used 5,159,697 ties less in 1910 than in 1909. All the white pine and chestnut ties purchased in 1910 were purchased by steam roads.

Hewn cypress ties were imported, but not used by steam roads.

With electric roads 61.4 per cent. of the ties purchased were hewn, as contrasted with the steam roads, where 70 per cent. were hewn. Douglas fir constituted 50 per cent. of the sawn ties and cedar constituted 34 per cent. Cedar made up 57 per cent. of the hewn ties and Douglas fir 20.7 per cent. The species which are chiefly used sawn are cedar, Douglas fir and oak. The species which are chiefly used hewn are hemlock, tamarack, cypress, spruce and jack pine. All the cypress and jack pine ties used were hewn. The average price of hewn ties was 37 cents, or 2 cents per tie less than was paid by steam roads. It is interesting to note that whereas with steam roads hewn ties cost 3 cents per tie more than sawn ties, with electric roads sawn ties cost 9 cents per tie more than hewn ties.

Imports from the United States of cross-ties in 1910 amounted to $1,096,832. Exports in 1910 were 1,995,582 ties at a value of $463,508. Of this total $376,913 was to the United States. The balance of imports over exports was $633,324, which represents about 891,000 ties at the average price paid for ties in Canada in 1910.

Two plants are now being established for the chemical treatment of railway ties. One is being erected at Fort Frances, Ontario, and the other is being started at Winnipeg. It is stated that a plant will also be erected at Vancouver. The plant at Fort Frances will be capable of treating 2,000 ties per day. The zinc-chloride-aluminium patent immersing process will be used, which both prolongs the life of the timber and rends it fireproof. It is questionable if this process will give as good results in Canada as would creosote.

This is a matter which for some years has been necessary for the preservation of the forests of Canada. At the same time it would have reduced the annual cost of railway maintenance. The average life of untreated ties as reported by the steam roads is: cedar, 9 years; tamarack, 8 years; hemlock, 7 years; Douglas fir, 7 years; jack pine, 6 years; spruce, 6 years. As may be noted from the tables, cedar is the species principally used, because of its durability, but the supply of cedar is rapidly becoming exhausted. Unless preservative treatment of ties is introduced, the species of short life will have to be used untreated, which, on account of the necessary frequent renewal, will increase the cost of mileage maintenance. If treated ties were used, which would cost about 30 cents extra per tie for creosoting and equipping with tie plates, the inferior species, which are very plentiful and cheap in Canada, could be used with economy. With such a treatment these woods would last at least 15 years, and if protected from wear would probably last much longer.

The lodgepole pine of the West would be greatly increased in usefulness by this treatment. This species is used chiefly for mining timbers and props and occurs, fire-killed, in vast areas on the mountain slopes of Alberta and British Columbia. It cannot be used for lumber, on account of checking, and, if untreated, it lasts only about 5 years when used for railway ties. At present this wood stands dead and perfectly seasoned and would take chemical treatment readily, after which it would make lasting and economical ties. By the use of such inferior qualities of timber, railway companies would assist conservation and at the same time decrease the cost of railway maintenance.

HILL ROADS IN CANADA.

The Canadian Northern Railway has granted trackage rights from Emerson, Man., on the international boundary line, to Winnipeg, 68 miles, to a new company formed in the interest of the Great Northern and the Northern Pacific. The new corporation is known as the Midland Railway of Manitoba. The agreement is for 20 years with a provision for extending it to a total of 999 years.

Trains of the United States roads are allowed to be run into Winnipeg but are not to do any local business unless by order of the Railway Commission, in which case the Canadian Northern is to have 80% of the gross receipts. The rental of the Winnipeg Terminal is to be $2.50 for each revenue train movement, with 50 cents additional for every car above eight, and certain other charges.

The line to be used is a part of the 355 miles of Northern Pacific's road in Manitoba, all of which was leased in 1901 to the provisional government for 999 years and subleased by it to the Canadian Northern.

PERSONAL.

MR. W. H. SCOTT has been appointed general agent for the Manitoba Government Telephone Commission.

MR. W. W. POWELL has been appointed land surveyor in the offices of the city engineer of Vancouver, B.C.

MR. H. RUSSELL HILL, B.A.Sc., was recently appointed to the position of sales manager for the Tagona Water and Light Company at Sault Ste. Marie, Ont.

MR. F. F. LONGLEY, resident engineer of the Toronto filtration plant, has resigned his position on the city's service and has accepted a position in the firm of Allen Hazen, New York.

MESSSRS RIDOUT AND MAYBEE, patent solicitors, are removing from their present premises at Manning Chambers to new and more commodious quarters at 59 Yonge Street, corner of Colborne Street. Owing to the increase in the legal business of the firm, Mr. J. F. Edgar, barrister-at-law, has now been associated with the firm as counsel.

MR. C. H. RUST, municipal engineer, city of Victoria, B.C., has been honored by the American Society of Civil Engineers, having been elevated to the position of First Vice-president, the first time in the history of the society that a Canadian has been so honored.

MEETINGS.

The 23rd annual convention of the Canadian Association of Stationary Engineers closed on July 25th last in Belleville, Ont., with the installation of the following officers,—President, J. A. Robertson, Stratford; vice-president, C. Cosford, London; conductor, F. H. Chester, Belleville; doorkeeper, H. L. Bishop, Hamilton; secretary, A. Kastella, Stratford; treasurer, W. E. Archer, Toronto.

COMING MEETINGS.

THE WESTERN CANADA IRRIGATION ASSOCIATION.—Sixth Annual Convention Kelowna, Okanagan Valley, B.C., August 13, 14, 15 and 16, 1912. Secretary, Normon S. Rankin, P.O. Box 1317, Calgary, Alta.

THE UNION OF CANADIAN MUNICIPALITIES.—August 27, 28 and 29. Meeting at City Hall, Windsor, Ont. Hon. Secretary-Treasurer, W. D. Lighthall, K.C.

CANADIAN FORESTRY ASSOCIATION.—Convention will be held in Victoria, B.C., Sept. 4th-6th. Secy., James Lawler, Canadian Building, Ottawa.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Second Annual Meeting to be held in Toronto, Sept. 16, 17 and 18.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Annual Assembly will be held at Ottawa, in the Public Library, on 7th October, 1912. Hon. Sec'y, [illegible] 5 Beaver Hall Square, Montreal, Que.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

EIGHTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.—Opening Meeting, Washington, D.C., September 4th, 1912. Other meetings, Business and Scientific, in New York, beginning Friday, September 6th, 1912 and ending September 13th, 1912. Secretary, Bernhard G. Hesse, Ph. D., 25 Broad Street, New York City.

INTERNATIONAL ASSOCIATION FOR TESTING MATERIALS.—Sixth Congress will be held in the Engineering Societies Building, 29 West Thirty-ninth Street, New York, Sept. 2-7, 1912. Secretary, H. F. J. Porter, 29 West Thirty-ninth Street, New York.

ILLUMINATING ENGINEERING SOCIETY.—Sixth Annual Convention to be held at Hotel Clifton, Niagra Falls, Ont., Sept. 16-19, 1912. Secretary, Preston S. Millar, 29 West Thirty-ninth Street, New York.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Ninth Annual Convention will be held in Cincinnati, December 3, 4, 5 and 6, 1912. The Secretary, 150 Nassau St., New York.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. [illegible] Ottawa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W. Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meet- [illegible]

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

[illegible] Secretary, Mr Hugh [illegible] Carter Cotton Bldg., Vancouver, B.C. Headquarters: McGill [illegible] ge, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; [illegible]

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone- [illegible] University of Manitoba, Winnipeg.

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewit, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President, J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Jas. Anderson, Gen. Mgr., Sandwich, Windsor and Amherst Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, A. F. Wickson; Toronto. Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, [illegible] Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, [illegible] Regina.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman; Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—[illegible] Secretary, [illegible]

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Hon. [illegible] Secretary, Norman S. Rankin, [illegible]

WESTERN CANADA RAILWAY CLUB.—President, [illegible] Secretary, [illegible] Winnipeg, Man. Second Monday, except [illegible]

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only, unless otherwise noted, at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close		Noted in issue of
8-5	—Electric Generating Machinery, Canora, Sask (S.)	7-18
8-31	—Trenching and Backfilling, Edmonton, Alta (S.)	8-8

(Canora specifications are also on file at the office of The Canadian Engineer, Rooms 617-628, Transportation Building, Montreal.)

COPIES OF ENGINEER WANTED.

One copy each of our issues of July 4th and 11th, 1912, are required. The usual extension of the senders' subscription will apply in this case.

TENDERS.

Dunnville, Ont.—Tenders for road machinery will be received until August 14th, 1912, by the Corporation of the County of Haldimand. For full particulars apply to Alan Mair Jackson, county engineer, Dunnville, Ont. (See advt. in Canadian Engineer.)

Eastview, Ont.—Sealed tenders addressed to the Reeve of the village of Eastview, will be received by H. R. Washington, secretary-treasurer, up to 4 p.m. Saturday, August 10th, 1912, for the construction of a concrete sidewalk along the northerly side of the Montreal Road from Cumming's Bridge to Notre Dame Cemetery.

Edmonton, Alta.—Tenders for trenching and backfilling approximately 25 miles will be received by the City Commissioners, city of Edmonton, until noon of August 31st, 1912. Specifications, etc., at the office of The Canadian Engineer, 62 Church Street, Toronto, or at the office of the Gas Engineer, city of Edmonton. (See advt. in Canadian Engineer.)

Edmonton, Alta.—Proposals for the design, manufacture and fixing complete of electric lighting fixtures for the Parliament Buildings, Edmonton, will be received up to 12 o'clock noon, August 31st, 1912, addressed to John Stocks, Deputy Minister of Public Works, and endorsed "Proposals for Lighting." Plans and particulars can be obtained upon application to the office of the provincial architect, New Parliament Buildings, Edmonton.

Fort William, Ont. — Sealed tenders addressed to the chairman of the Utilities Committee and marked "Tenders for water pipe," will be received up to August 28th next. (See advt. in this issue of Canadian Engineer.)

Grayson, Sask.—Sealed tenders will be received by W. B. Thomson, Town Secretary, until August 10th, at 6 o'clock p.m., for the erection and completion of a public hall building in the town of Grayson, Sask. Plans and specifications may be seen at the office of the above.

Guelph, Ont.—Tenders for the construction of bridges will be received until noon of Aug. 14, 1912, by the County Clerk of Halton County, at Milton. Plans and specifications may be seen at the county clerk's office, Milton, or at the office of Messrs. Malcolm & Rudd, engineers, Metropolitan Bank Building, Guelph. (See advt. in Canadian Engineer.)

Jackson's Point, Ont.—Tenders for the construction of a 90 ft. through truss steel bridge, with concrete abutments and concrete floor, at the mouth of the Black River, on Jackson's Point, will be received up to noon of August 17th, 1912. Plans and specifications at the office of Frank Barber, Esq., civil engineer, 57 Adelaide St. E., Toronto. (See advt. in Canadian Engineer.)

Montreal, Que.—Tenders will be received up to noon of 12th August, 1912, for the hiring of one or more spoon dredges; also one or more floating or land derricks for clamming material from flat scows to the shore; also one or more attending tugs and the necessary scows. Full particulars may be obtained upon application to Mr. F. W. Cowie, chief engineer. M. P. Fennell, jr., acting secretary, Harbor Commissioners of Montreal, Montreal.

Ottawa, Ont.—Sealed tenders addressed to R. C. Desrochers, Secretary Department of Public Works, will be received up to 4 p.m., August 28th next for the construction of a breakwater at Port Arthur, Ont. (See advt. in this week's issue of The Canadian Engineer.)

Ottawa, Ont.—Sealed tenders addressed to R. C. Desrochers, Secretary Department of Public Works, will be received up to 4 p.m. on Monday, July 10th, for the construction of a wharf at Metchosin, B.C. (Nanaimo District).

Ottawa, Ont.—Sealed tenders addressed to the Director of Contracts, Department of Militia and Defence, Ottawa, will be received up to noon of August 12th next for the construction of a fence around the military cemetery in Montreal.

Ottawa, Ont.—Sealed tenders addressed to R. C. Desrochers, Secretary Department of Public Works, will be received up to 4 p.m. Monday, August 26th, 1912, for the construction of a wharf and approach at Parry Sound, Ont.

Ottawa, Ont.—Tenders for additions and alterations to laboratory No. 1 experimental farm, Ottawa, will be received until August 24th. Plans, etc., at the office of R. C. Desrochers, secretary, Department of Public Works, Ottawa.

Ottawa, Ont. — Tenders for external painting, Work Point Barracks, Esquimalt, B.C., will be received up to noon of August 20th, 1912. Specifications, etc., may be seen at the office of the officer commanding District No. 11, Victoria, B.C., and the Director of Engineer Services, headquarters, Ottawa. Eugene Fiset, colonel, deputy minister, Department of Militia and Defence, Ottawa.

Ottawa, Ont.—Tenders addressed to A. J. Jarvis, Asst. Deputy Minister and Secretary of Agriculture, Ottawa, will be received up to noon of August 19th, for the several works and materials required in the erection and completion of a stable and barn at Rosthern, Sask. Specifications and plans at the office of the superintendent of the experimental farm station, Rosthern, Sask.

Ottawa, Ont.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, for the erection and completion of superintendent's residence at Lockport, Selkirk District, Man., will be received until August 20th, 1912. Plans and specifications at the department, and at the offices of W. Z. Earle, district engineer, Winnipeg, Man., and A. S. Innes, supt., Lockport, Man.

Redcliff, Alta.—Bids are wanted for the building of a ferry of the standard government type at Redcliff. Detailed drawings and blue print will be furnished upon application to C. W. White, secretary-treasurer of village.

Sherbrooke, Que.—Tenders are being called for two steel highway bridges for the township of Ascot, Quebec. W. W. Baker, secretary. Tenders close August 10th, 1912. Plans and specifications at the office of the secretary.

Toronto, Ont.—Sealed tenders endorsed "Tenders for Packing House," will be received by the Department of Public Works of Ontario up to Monday, August 12th, for the erection of a packing house at Jordan Harbor. Plans may be seen at the department and at the fruit station, Jordan Harbor, Ont.

Vancouver, B.C.—Messrs. Sharp and Thompson, 536 Hastings Street West, will receive (bulk and separate) tenders up to noon August 21st next, for the following trades: Constructural steel and concrete, bricklayer, stonemason, terra cotta, carpenter, external and internal millwork, bronze and ornamental iron, sheet-metal work, roofer, tiling and marble plasterer, painter and decorator, glazer. This is for a new club house to be erected in this city.

Vancouver, B.C.—The city council have accepted the recommendation that tenders be called for the paving of Seaton Street, which will involve the construction of an expensive sewer.

Winnipeg, Man.—Tenders for the manufacture and delivery f.o.b. at the power house, Point du Bois, Man., of one 300 k.w. 3 phase transformer, will be received until noon of August 14th, 1912. Specifications, etc., at the office of the City Light and Power Department, 54 King St., M. Peterson, secretary, Board of Control office, Winnipeg.

Winnipeg, Man.—The Chairman, Board of Control, will receive tenders [illegible] of August [illegible], for the supply of [illegible] Specifications, etc., may be obtained at the office of the City Engineer, [illegible] James Avenue. M. Peterson, secretary, Board of Control office, Winnipeg.

County of York, Ont.—Tenders for the construction of [illegible] River at [illegible], in the County of York, will be received up to noon of Saturday, August [illegible]. Plans and specifications at the office of Frank Barber, Esq., county engineer, 57 Adelaide St. E., Toronto. (See advt. in Canadian Engineer.)

Township of York, Ont.—Tenders for the construction of [illegible], Township of York, will be received at the office of Frank Barber, Esq., township engineer, 57 Adelaide St. E., Toronto, up to noon of August [illegible]. Plans and specifications at the office of the engineer. (See advt. in Canadian Engineer.)

CONTRACTS AWARDED.

Buchanan, Sask.—Messrs. Hanks and Bertram, Canora, Sask., have been awarded the contract to erect a school building in this municipality.

Calgary, Alta.—Messrs. John Gunn and Sons, of Winnipeg, have secured the contract for the Canadian Northern bridge across the Bow River inside the city of Calgary limits at a price said to be $150,000.

Georgetown, Ont.—The tender calling for the erection of a combined bridge and dam over the Credit River has been awarded to Frank Barber, 57 Adelaide St. E., Toronto. The contract is let on a cost basis plus a fixed extra for professional services.

High River, Alta.—The John McDougall Caledonian Iron Company, Montreal, have been awarded the contract to build and install the pump in a new pump house that will be constructed by this municipality by day labor.

North Toronto, Ont.—J. T. Connolly, 606 Avenue Road, Toronto, has been awarded a contract to lay 30,000 square yards of asphaltic concrete at $1.90 per square yard, and construct 5 miles of storm sewer at a unit price.

J. H. McKnight Construction Company, Toronto, have been awarded a contract to lay 30,000 square yards of Dolarway pavement at $1.70 per square yard.

J. K. Allen, Toronto, has been awarded a contract to lay 30,000 square yards of Tarvia pavement at $1.25 per square yard.

North Vancouver, B.C.—The city council have awarded a contract to W. Evans Company, to lay a cement sidewalk with gutter, curbs, etc., on Lonsdale Avenue. The price for the work is $3,905.50.

Penticton, B.C.—Messrs. Grant, Smith and Company, of Spokane, have been awarded a contract to construct fifty-seven miles of the Kettle Valley Railway.

Regina, Sask.—Messrs. Wilson and Wilson have been awarded the contract to erect an addition to the Regina Institute at a cost of $88,500. Other bidders and their tender prices were: R. J. Lecky and Company, Regina, $109,962.; Parsons Building Company, Limited, $95,580.; Smith Bros. and Wilson, $90,000.

South Vancouver, B.C.—The contracts for the four new schools in the municipality were let by the school board to Messrs. McPhalen Bros., whose tenders were the lowest received. The total cost of the construction of the schools will be $142,000, divided as follows: Sexsmith, Sixty-first and Ontario, $35,300; Secord, Victoria Road and Sixty-first, $36,200; Gordon, Ferris and Knight Roads, $35,700; Norquay, Ferguson Road, $35,200.

Vancouver, B.C.—The recommendation of the city engineer for the awarding of the contract for the paving of Broadway Bridge to Laurel, to La Placa Bros., at $47,636 was accepted, as well as another recommendation giving a contract to the same firm for the resurfacing of Main, Hastings to Harris, at $10,340.

Victoria, B.C.—On the recommendation of the Electric Light Committee of the city council the tender of Hutchison Bros. for installing a lighting system on portions of Government Street and Dallas Road was accepted. The contract price for the first mentioned thoroughfare is $10,350 and for Dallas Road, $6,648.

Winnipeg, Man.—The city council has accepted the tender of the Canada Cement Company for from 15,000 to 25,000 barrels of cement to be delivered this year at $2.40 per barrel gross, including sacks.

◆

RAILWAYS—STEAM AND ELECTRIC.

Calgary, Alta. — The Canadian Pacific Railway will double track about eight miles of its track from the Ogden shops through the city to Sunalta.

Halifax, N.S.—The receipts from the operation of the Halifax Electric Tramway Company, Ltd., for the week ending July [illegible], showed a decrease in comparison with a similar period last year. They are as follows:

1911	1912	Decrease.
$7,591.50	$7,440.07	$151.43

Hamilton, Ont.—A report states that a project calling for the construction of a new incline to carry street cars to the top of the hill behind the city is under way. Mr. T. F. Webb is interested in the project.

Tarvia

Preserves Roads
Prevents Dust–

Main Street, Wolfville, N.S., Constructed with Tarvia X.

Millions of Yards Treated

FOR a hundred years macadam roads have been standard. The motor driven vehicle, however, added a new destructive element to road wear that macadam had not provided for. A stronger binder than stone dust was found necessary to hold the road together under this traffic.

The new conditions brought forth a variety of bituminous binders. Of these Tarvia, manufactured from refined coal tars, was the first to be used and is now standard for this purpose.

Tarvia is made in three grades—"Tarvia X" for road and pavement construction. "Tarvia A" for hot surface application, and "Tarvia B," applied cold, for dust prevention and road preservation.

Millions of yards of macadam have been successfully tarviated in all parts of the country. The use of Tarvia waterproofs the macadam, prevents its disintegration, keeps down the dust and gives a surface that is smooth, well bonded and automobile-proof.

Towns and cities which have used Tarvia for a number of years are proud of their roads and pavements, while the records show that its use has been most economical—the saving in maintenance expenses having generally more than paid for the cost of the treatment.

Booklet showing roads in various parts of the country treated with Tarvia and giving details of the process mailed free on request.

THE PATERSON MANUFACTURING COMPANY, LIMITED
MONTREAL TORONTO WINNIPEG VANCOUVER

THE CARRITTE-PATERSON MANUFACTURING CO., LIMITED
ST. JOHN, N.B. HALIFAX, N.S.

LIGHT, HEAT AND POWER.

Duncan, B.C.—It is the intention of this municipality to erect a power plant at Skutz Falls, on the Cowichan River.

Moose Jaw, Sask.—The new generator at the Manitoba Street station has been connected with the mains. Many householders and power users are now receiving a normal supply.

Welland, Ont.—The ratepayers voted in favor of spending $45,000 on a hydro-electric service to light the streets, stores and residences. The vote was 329 for and 183 against. D. Black, town engineer.

◆

GARBAGE, SEWAGE AND WATER.

North Vancouver, B.C.—The municipal council have decided to finish the Rice Lake tunnel. Ald. Dick is chairman of the Water Works Committee.

Ottawa, Ont.—The municipal council have started negotiations with Mr. Allen Hazen, of New York, regarding the erection of a mechanical filtration plant on Lemieux Island. Mr. Weston Fuller, Ottawa, is looking after Mr. Hazen's interests in this matter for the present.

◆

BUILDINGS AND INDUSTRIAL WORKS.

Edmonton, Alta.—Plans have been completed for the erection of a new barracks for the R.N.S.M.P in this city. It is to cost $70,000. Messrs. Nesbitt and Miller are the contractors and Rowland W. Lines is architect.

Fort William, Ont.—A company taking the name of the Mount McKay Pressed Brick Company has been formed, and will expend $200,000 on a plant. Mr. James Gowanlock, Dr. W. H. Hamilton, and W. A. Dowler, K.C., all of Fort William, are the organizers.

Lethbridge, Alta.—The federal government will erect a laboratory at the quarantine station for the purpose of veterinary medical research. The plans for the new building are being prepared by Ernest Carver, of this city. The building will be two stories and of brick construction.

Montreal, P.Q.—Messrs. Mackenzie, Mann and Co. will erect construction plants near the site of the new tunnel. These buildings will be of frame covered by galvanized iron, and they will contain steam driven air compressors, steam boilers, steam and electric hoists and derrick and electrical ventilation blowers. The buildings will be surrounded by high fences.

North Toronto, Ont.—The Finance Committee have re- [illegible]

BRIDGES, ROADS AND PAVEMENTS.

Fredericton, N.B.—The municipal council has decided to lay more Tarvia pavement than was first proposed, and to cover the Hassam pavement with the same material.

Hamilton, Ont.—At a meeting of the Cost and Material Committee of the projected Toronto-Hamilton highway, the following recommendations were adopted. That the roadway be eighteen feet in width with a space of three and a half feet on each side, the eighteen-foot strip to be constructed with a concrete base and brick or other topping. The cost of this work was estimated at $600,000. T. Kennedy, Dixie, Ont., president of the committee.

Prince Rupert, B.C.—The municipal council have adopted the recommendations of the acting city engineer, Mr. Mason, regarding a sewer system. The plans provide for a system of concrete modern sewers, egg-shaped in section, according to the latest ideas, and calculated to carry off all surface water as well as sewage.

Toronto, Ont.—The Works Commissioner will recommend a steel bridge on St. Clair Avenue to replace the concrete work which was damaged recently.

Vancouver, B.C.—The Railway Commission have ordered the construction of a bridge across the second narrows at a cost of $2,000,000. City Engineer of Vancouver, F. L. Fellows.

◆

FIRES.

Montreal, P.Q.—The premises of the Montreal Abattoirs, Ltd., were damaged by fire to the extent of $200,000.

Vancouver, B.C.—The furniture plant of Max Freed was destroyed by fire with a loss of $70,000.

◆

CURRENT NEWS.

Berlin, Ont.—The ratepayers will vote August 31st on the following proposals: To spend $15,000 for the erection of a tuberculosis sanitarium; to spend $17,000 on an addition to the car barns and for the purchase of two new cars; to spend $5,000 for the erection of a civic abattoir; to spend $6,000 on the erection of municipal barns; to spend $6,000 on a bridge across the Grand River. H. Johnston, city engineer.

Dauphin, Man.—It is reported that local contractors have so much work on hand that the erection of a new church has had to be postponed and that several hundred additional mechanics could find employment here.

Montreal, P.Q.—Mr. Philippe Herbert has had his design accepted by the committee of judges for a memorial to His Late Majesty King Edward VII. The design shows King Edward in his official robes and in a very life-like pose, holding the sceptre of state, and provides for a granite pedestal thirty feet high, of exceedingly handsome and massive design, while the bronze figure of the King will be ten feet high, making forty feet in all.

New Westminster, B.C.—Friction has arisen between the municipal council and the gas company in this city, the former claiming that the franchise of the latter has expired and threatening damage action if pipe laying is continued.

Ottawa, Ont.—The government has received five tenders for the construction of the elevator at Fort William, Ont., as follows:—J. A. Jamieson, Barnett McQueen, the J. S. Metcalfe Co., J. H. Tromanhausen, the Canadian Stewart Co.

St. Catharines, Ont. — Another accident caused by a [illegible] the Welland Canal, caused considerable damage and obstructed navigation for several hours.

CANADA'S PACIFIC COAST

Mr. E. J. Chamberlin's recent statement that the Panama Canal will not affect the shipment of grain eastward, has caused considerable comment on the coast. Vancouver and New Westminster have been looking for almost immediate shipments of grain, especially in view of the great congestion that annually occurs on the prairie, and which is growing greater with the expansion of production of wheat. Mr. Chamberlin declares that the tropical heat will so affect grain in transit that it cannot be shipped via Canada's western Canadian ports, which will include Prince Rupert, once the Grand Trunk Pacific is completed. This point has been raised before though not by an official and public man of Mr. Chamberlin's standing. As an argument it may be stated that grain is shipped every year and has been shipped for many seasons past from Seattle, Tacoma and Portland, the ultimate destination being Europe. This grain passed through the tropics in transit, and it has not been so ruined that the traffic has ceased.

This point is argued also by Senator R. H. Pope, who was on the coast recently. He says that this danger may be relieved if not entirely avoided by giving the wheat a chance to dry after it is threshed.

He makes the suggestion that the government should advance farmers money on their crop at a reasonable interest to enable them to hold it until they can sell advantageously.

This point will apply further than in reference to quick marketing of wheat for exports. Farmers cannot afford to hold their wheat, for they need the money badly by autumn, and as a result they sell as soon as they can get the grain to the nearest elevator. The result is that they often have to take what is offered, accept the buyer's grading and are subject to many methods whereby they are deprived at times of their full measure. If Mr. Pope's suggestion could be carried into effect it would mean a great deal to the farmer on the prairie who is doing much to give Western Canada stability.

Insofar as quick marketing affects export via the western ports of Canada, those interested in the question here do not anticipate that the flow of grain to the Pacific coast can be stopped. In the meantime, the necessary preliminary arrangements are going ahead to provide facilities for shipment.

This week another railway move has been made. The Pacific Great Eastern has filed its plan through North Vancouver, and makes the announcement that five surveying parties are in the field on the projected route to the north. Mr. D'Arcy Tate, of the Grand Trunk Pacific, is on the coast and the statement is given out that the Grand Trunk Pacific will buy out the new company. When Sir Richard McBride made public his railway policy in the House last winter, The Monetary Times pointed out that the Pacific Great Eastern was really intended for the Grand Trunk Pacific's accommodation between Fort George and Burrard Inlet. This was denied at the time, but present developments seem to show that the statement was right.

It looks as if coal will be extensively mined in the northern part of the province within the next year or two, though it is hardly probable that mines will be in operation before the completion of the Grand Trunk Pacific, which would provide facilities for shipment to interior points. Eastern Canadians and London financiers are interested in the British Columbia Anthracite Syndicate, which has large coal land holdings in Groundhog Basin in the Skeena district. This company obtained a charter at the last session of parliament to build a [illegible]. A route map has now been filed with outlet for the railway on Portland Canal. Sir [illegible] has acquired options on coal fields in the same basin, and has had [illegible] in the coal fields. Development of these coal measures on the coast will aid the proposal to establish iron works on the Pacific shore. The iron ore is here, and all that has been wanting is coke at a price low enough to warrant the initiation of the enterprise.

Timber as an investment has been recognized during the past two or three years, and it is realized that it will greatly increase in value during the next five years. That is why a considerable amount of money from Europe has come into British Columbia. Visiting timbermen from the United States are quick to tell what is going to happen for they can see conditions of fifteen or twenty years ago in the middle states being duplicated on the Pacific coast. For that reason, Mr. Hans Dierks, of Kansas City, who was here recently, advises owners to sit tight, for lumber manufacturers will have to come to British Columbia, and this opinion is held by other prominent lumbermen.

GRAIN GROWERS GRAIN COMPANY.

The Grain Growers Grain Company, which is the organization of the Western Canadian Farmer, held their meeting in Winnipeg on July 16th, under the presidency of Mr. T. A. Crerar. The years' statement showed a net profit of $121,614, against $69,000 the previous year and but $790 five years ago. The paid-up capital is $568,000, and, after paying a ten per cent. dividend, $60,000 was added to the reserve fund, which now stands at $200,000, this despite the difficulty in handling last year's crop, owing to low grades, tough wheat and traffic congestion.

The president said that the company had practically closed with the Canadian Pacific Railway a deal whereby they would lease the big terminal elevator "B" at Fort William, Ontario, and with the Manitoba Government for leasing its extensive system of internal elevators, both of which projects the meeting was asked to ratify. The company had also acquired timber limits in British Columbia estimated to contain 300,000,000 feet.

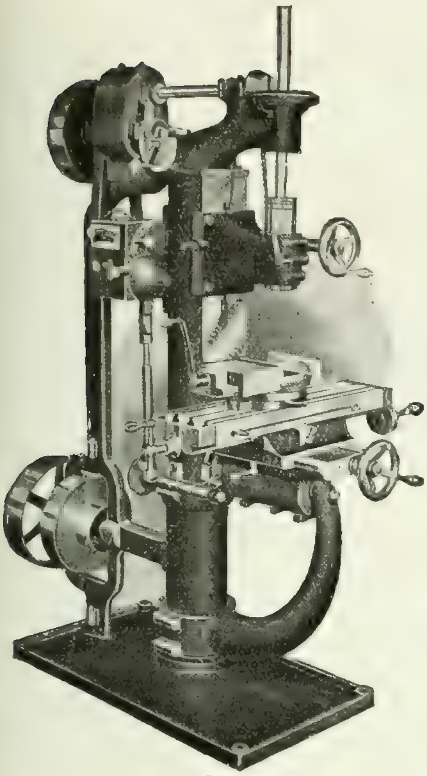
The profits of the company for previous years were as follows: 1911, $69,575.46; 1910, $59,663.78; 1909, $53,000; 1908, $30,190.24; 1907, $790.54.

Speaking of future developments, Mr. Crerar favored the local unit method as practised by the farmers' elevators of Minnesota and the Dakotas, whereby other classes of merchandise were successfully handled by country elevators. It was necessary to secure best results to maintain the staffs all the year round, and lumber, binder twine and implements could be profitably handled during the summer months. He advocated the securing of a good coal area, as coal and lumber were rapidly going under control of combines. He favored selling to everyone, but giving a discount to their shareholders. Units would be built up by issue of stock to local subscribers, and there was no reason why in time the successful merchandising of the British co-operative societies should not be duplicated.

The company might further secure connection with a mortgage corporation and secure cheap money for farmers. The money power in Canada, he said, was becoming a menace and its evil possibilities might largely be overcome by co-operative credit societies.

NEW GAS ENGINE AGENCY.

Messrs. Richard Hornsby and Sons, Ltd., of Grantham, England, makers of the well known Hornsby-Stockport gas engines and suction plants, have just opened a Canadian office in the Cartier Building, 212 McGill Street, Montreal, in charge of Mr. [illegible] H. Anderson. For a number of years now this firm has been selling their engines in Canada with considerable success and in order to further develop their trade throughout the Dominion the Montreal office has been opened so as to render still more efficient service to intending purchasers in various parts of the Dominion.



You Need a Machine Like This on a Dozen Different Jobs

It's a No. 2 Knight Milling and Drilling Machine

This machine is very rigid, powerful and accurate, so that close work may be turned out with a high degree of satisfaction, and in the shortest possible time. The adjustments are quickly and easily made. On a large variety of work it is possible to make a saving of from 20 to 50 per cent. in time, as compared with other machines.

The fact that hundreds of Knight Machines are now in use in this and foreign countries proves that they are not experiments.

These machines are made in three sizes.

Briefly, the construction of the No. 2 Knight Miller is as follows:—Spindle of crucible steel, ground bearings; working surface of table, 29 × 8½ inches; feed, longitudinal and transverse; floor space, 60 × 68 inches; weight, crated for shipment, about 2,500 lbs.

TRADE ENQUIRIES.

The following among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending July 22nd, 1912:—

The commercial manager of an English firm manufacturing a patent lighting system is about to visit Canada with a view to appointing agents in each province.

A London firm stated to have a regular market for from three to four thousand tons of soft, smooth graphite per annum, desire to be placed in touch with actual mine owners in Canada.

A Johannesburg correspondent desires to secure agencies for Canadian manufacturers open to do business in South Africa.

From the branch for city trade enquiries, 73 Basinghall Street, E.C.

A Yorkshire company manufacturing petrol and paraffin engines, also a large variety of machine tools, wish to arrange for their sale in Canada.

◆

MINERALS IN QUEBEC.

The annual report of the Mines Branch of the Province of Quebec for 1911 has been issued, showing that last year the value of the production of the Quebec mines amounted to $8,679,786. This is an increase of $1,356,505, as compared with the preceding year. From about two million dollars in 1899, the value of minerals has climbed up to over eight and a half million dollars. In 1911, the mines of the province produced asbestos, copper ore, iron ores, mica, graphite, magnesite, and all kinds of structural materials.

Dr. J. A. Bancroft, professor of geology at McGill University, Montreal, reports on the region between the Kinojovis and the Harricanaw Rivers.

◆

A BOG PATCH NOT TAKEN INTO ACCOUNT.

A patch of boggy ground near Ardley on the line of the Great Northern Railway about five miles out of Vancouver, B.C., has been giving the engineers and maintenance-of-way men trouble during the last few days. The spot has got so soft during the last few days that it was considered unsafe to run trains over it and consequently passengers are being transferred at that point until the trouble can be remedied. Soundings in this particularly boggy spot have developed the fact that it is possible to go down nearly 300 feet before the underlying country hardpan is reached or any other kind of a firm foundation. The trouble is said to have developed through the piling up of material for the laying of a double track at that point, the extra weight causing the soft foundation to sink. The engineers are puzzled as to just what to do but meanwhile filling-in operations are being continued with a view of securing a substantial foundation.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

[illegible] Board of Railway Commissioners [illegible] date [illegible]

[illegible]

[illegible] Ry. between mileage 82.8 and 121.51 northerly from Hobon, on C.P.R. main line.

[illegible]

17053—July 17—Authorizing Campbellford, L. Ont. & W. Ry. to cross highways from mileage 128.9 to 131.23, in Twp. of Hope, County of Durham, Ontario.

17054—July 17—Authorizing Atlantic, Quebec & Western Ry. to open for carriage of traffic its line between Grand River Station, mileage 51½, and Gaspe Station, at mileage 102½.

17055—July 17—Naming express delivery and collection limits for city of Estevan, Sask.

17056—July 16—Authorizing C.P.R. to construct spur for Saskatoon Tent & Mattress Co., Saskatoon, Sask.

17057—July 17—Authorizing C.N.R. to cross 9 highways on its Alsask Southeasterly Branch.

17058—July 17—Authorizing James Bay & Eastern Ry. (C.N.R.) to construct bridge across Salmon River, mileage 22.1.

17059—July 17—Authorizing V.V. & E. Ry. to open for carriage of traffic its line from Abbotsford to Kilgard, B.C.

17060—July 17—Authorizing C.P.R. to construct spur for Winnipeg Supply Co., Ltd., Winnipeg, Manitoba.

17061—July 19—Authorizing C.P.R. to revise grade of present main line and construct additional main line track from mileage 17.35, Farnham S.D., to Iberville Jct., thence to mileage 41.8 to Highlands, Que.

17062—July 18—Authorizing C.P.R. to construct spur for Roofer's Supply Co., Ltd., Toronto, Ont. (Esplanade Street).

17063—July 18—Authorizing C.N.Q. Ry. to cross public road in Parish of St. Eustache, Que., County Two Mountains.

17064—July 5—Galt Interswitching, providing for same by G.T.R. in Galt, Preston and Hespeler, etc., Berlin and Waterloo.

17065—July 15—Authorizing C.N.O. Ry. to cross Jacques-Cartier and Union Ry. (G.T.R.) near Jacques Cartier Jct., Que. Interlocker to be installed.

17066—July 20—Re C.N.R. and G.T.P. spur to Tuxedo Park Co., Winnipeg, Man., apportioning cost of work, etc.

17067—July 17—Authorizing C.N.R. to cross public road on its Alsask Southeasterly Line.

17068—July 19—Authorizing G.T.R. to construct certain bridges on its Holmedale Branch, Brantford, Ontario.

17069—July 19—Directing G.T.R. to file within 15 days plan of location of station proposed at level crossing between tracks of G.T.R. and G.M. & S. Ry. at St. Gregoire; that St. Gregoire be established as regulation station with telegraph communication between Doucet's Landing and Victoriaville; that the Q.M. & S. Ry. be required to construct platform at proposed station for the transfer of passengers from G.T.R. to Q.M. & S. or vice versa.

17070—July 15—Approving of the C.P.R. station (proposed change) at Bredenbury, Sask.

17071—July 15—Approving of proposed change in location of C.P.R. station at Merritt, B.C.

17072—July 20—Directing the C.P.R. to appoint and maintain a permanent watchman, day and night, at crossing at mileage 101.6, Boundary Subdivision, near Fisherman, B.C.

17073—July 19—Authorizing Toronto Eastern Ry. to cross public road between Townships of Pickering and Whitby, in Concession 2 of each of the said Townships.

17074—July 19—Authorizing the C.L.O. & W. Railway to construct bridges 180.2 and 180.13, at Little Rouge and Big Rouge Rivers.

17075—July 19—Authorizing C.P.R. to construct spur on premises of Provincial Reformatory, on Lot 3, Con. 1, Twp. of Guelph, Ontario.

17076—July 19—Approving of proposed shortening of track circuit in connection with crossing bells at Argyle Street, Renfrew, C.P.R.

17077—July 19—Approving of proposed interlocking and signal device to be used in operating over the Lachine Canal by C.P.R.

17078—July 19—Authorizing C.N.O. Ry. to cross public road between Cons. 16 and 17, Township of Ferris, Dist. of Nipissing, Ont.

17079—July 19—Approving of C.N.O. Ry. station grounds at Smith's Falls, Ont., subject agreement between town of railway company, dated June 3, 1911.

17080—July 20—Authorizing C.N.O. Ry. to cross G.T.R. near Davenport Road, Toronto, question of taking of lands left to Chief Engineer of Board.

[illegible]—July [illegible]—Directing G.T.P. Ry. to repair approaches to crossing within 30 days under penalty of $25 on property of Donald McKenzie, Kirk, Alberta.

[illegible]—July [illegible]—Authorizing Lachine, Jacques Cartier & M. Ry. (G.T.R.) to take lands of Montreal, Park & Island Ry. in Parish of St. Laurent, Montreal, 597 ft. 100-ft. wide.

[illegible]—July [illegible]—Approving C.P.R. plan for steel trestle of bridge No. 26.8, and reconstruct bridge 109.4 on its Suffield-Kipp and Muskoka Subdivisions.

[illegible]—July [illegible]—Authorizing G.T.R. to construct spur for New Burford Canning Co., Ltd., County of Brant, Ontario.

17086—July 22—Approving proposed station and site of G.T.P. B.L. Co. at [illegible] Boundary Branch, Sask.

17087—July 20—Directing Dominion Atlantic Ry. to install gates at Gerrish Street, Windsor, N.S.; 20 per cent. from Railway Crossing Fund.

17088—July 23—Dismissing application Board of Trade, Pelly, Sask., re delay to shipments of freight C.N.R.

[illegible]—Directing C.N.R. to within [illegible] days to file plan for station at [illegible], Ont.

17090—July 22—Authorizing Toronto Suburban Ry. to cross C.P.R. Sudbury Division, by means of an undercrossing in Twp. of Vaughan, County of York, Ontario.

[illegible]—Authorizing C.N.O. Ry. to construct its line of railway across [illegible], District of Nipissing, Ontario.

[illegible]—Authorizing Campbellford, Lake Ont. & W. Ry. to cross Whitby, Port Perry and Lindsay Branch of G.T.R. at mileage 163.46, from [illegible].

17091—July 22—Authorizing C.P.R. to construct bridge No. 170.57 over [illegible] C.L.O. & W. Ry.

[illegible]—Approving [illegible] C.P.R. station on Lot 18, Con. [illegible], [illegible] C.L.O. & W. Ry.

The Canadian Engineer

An Engineering Weekly

THE HIGH TENSION TRANSMISSION SYSTEM OF THE HYDRO-ELECTRIC POWER COMMISSION OF ONTARIO.

FOURTH ARTICLE.

Dundas Station.—The Dundas station (Fig. 25) is the main interswitching station of the present system, and from here the outgoing transmission lines radiate to the various sub-stations.

The station equipment consists of four 750 kv-a. oil insulated, water cooled, 110,000 to 13,200-volt Westinghouse step-down transformers, employed to supply the city of Hamilton and vicinity; seven 110,000-volt Westinghouse electrically operated circuit-breakers equipped with condenser type bushings; six sets of outdoor type, 110,000-volt, electrolytic lightning arresters and two sets of 13,200-volt, electrolytic lightning arresters.

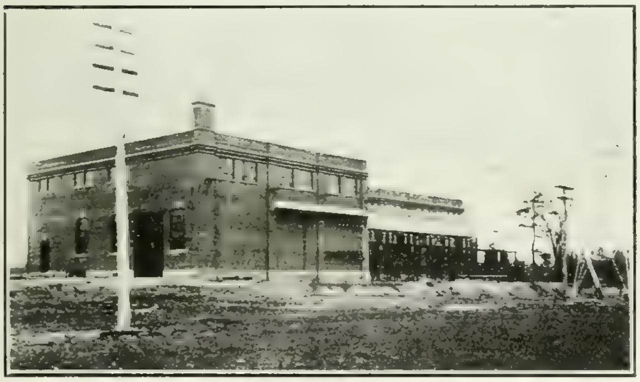

Fig. 25.—The Dundas Inter-switching Station.

Seven 110,000, three-pole automatic solenoid-operated oil switches, one for each incoming and outgoing line and one for each bank of three 750-kv-a. transformers are also installed. Two sets of 110,000-volt buses are supported on horizontal I-beams near the roof, in a manner similar to those at the Niagara Falls station. Disconnecting switches are provided on the line side of the oil switches, while on the station side two sets are installed and so arranged that any of the lines may be connected to either set of buses. (Fig. 26).

The same method of installing and removing transformers is employed as at Niagara. In fact, the same arrangement is in all stations in the system. The transformers are connected star delta with low-tension winding potential of 13,200 volts. A spare transformer is provided to replace the transformers of the connected bank, in case any of them become disabled.

The 13,200-volt switches and busbars are enclosed in concrete cells. The present structures accommodate the transformer switch, two line switches, and the service transformer switch. They are all automatic, electrically controlled oil switches, each provided with relays best suited for the requirements of the service for which they are employed. Service transformers are provided to supply light and power to the station. Three oil-insulated, self-cooled, 75-kv-a. transformers, stepping down from 13,200 to 2,200 volts serve the town of Dundas. (Fig. 27).

The apparatus in the station is operated from an enclosed control room situated at one end of the high-tension switch room, in which are located the main control and service boards, similar to those at Niagara. The control switchboard carries all the control switches operating at 110-volt d.c. for the remote control of the high and low-tension power switches, and also the meters. The service board is a regular switchboard employed to distribute the power to the different lighting and power circuits in the station.

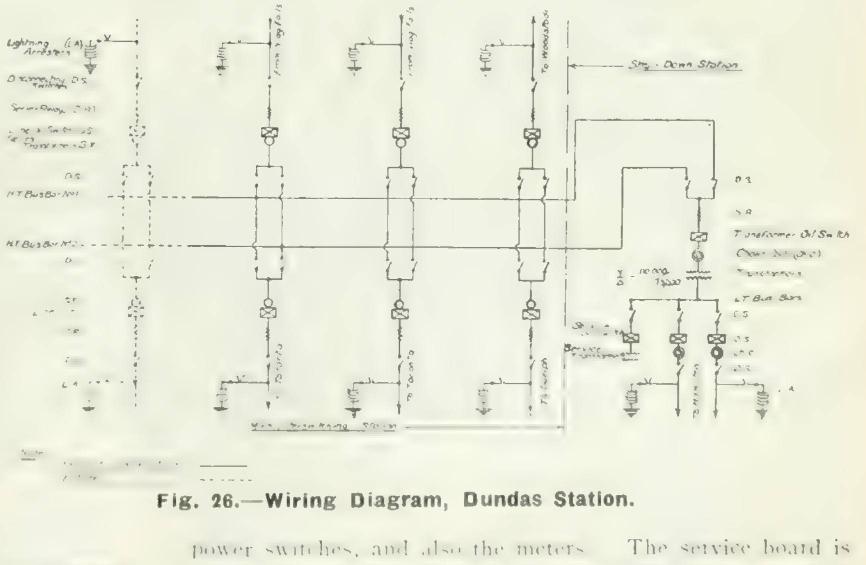

Fig. 26.—Wiring Diagram, Dundas Station.

The mechanical and cooling equipment in general is the same as in the step-up station.

Condenser bushings are used in both the Niagara Falls and the Dundas stations on all high-tension switches and transformers. The Canadian Westinghouse Company furnished and installed the entire equipments, with a few exceptions, of these two stations. Arrangements are being made at the present time for the installation of an additional bank of transformers and the necessary switches. (Fig. 28).

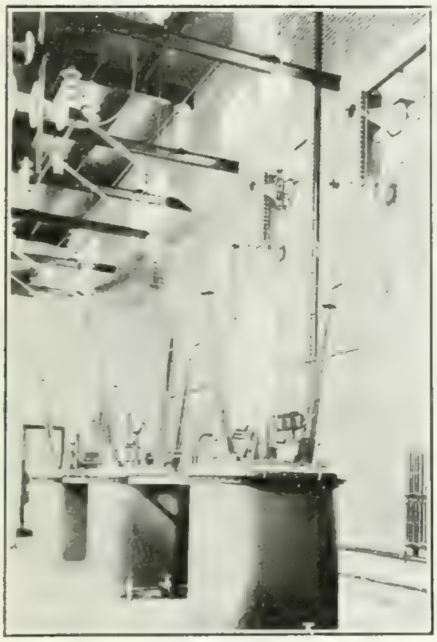

Fig. 27.—110,000-Volt Breaker Unit, Dundas Station.

Toronto Station.—This station (Fig. 29) is divided into three rooms, each running the entire length of the building, and consisting of the high-tension switching, transforming, and the low-tension switching sections.

The incoming lines are protected by electrolytic arresters placed within the building, and provided with horn gaps mounted on steel structures outside. The hoods for the outlets are built with a floor, upon which the entrance bushings, consisting of stacked porcelain rings with a pronounced petticoat, are mounted. The different sections of the bushings are clamped together with a brass bolt extending through the centres, the intervening spaces between the brass and porcelain being filled with concentric fibre rings and insulating compound. Since the arresters are placed inside and the horn gaps outside the building, six bushings are required for each line. [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] on the inner side of the arresters.

The [illegible] oil switch equipment [illegible] [illegible] [illegible] [illegible] [illegible] bushbar circuits. The [illegible] [illegible] [illegible] [illegible] [illegible] are similar to those at Niagara Falls and Dundas, with the exception that the [illegible] [illegible] are of a [illegible] [illegible] type. [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] built of annular ringed sections of compound clamped together, the interior space being filled with concentric cylinders of treated fibre compound. (Fig. 30).

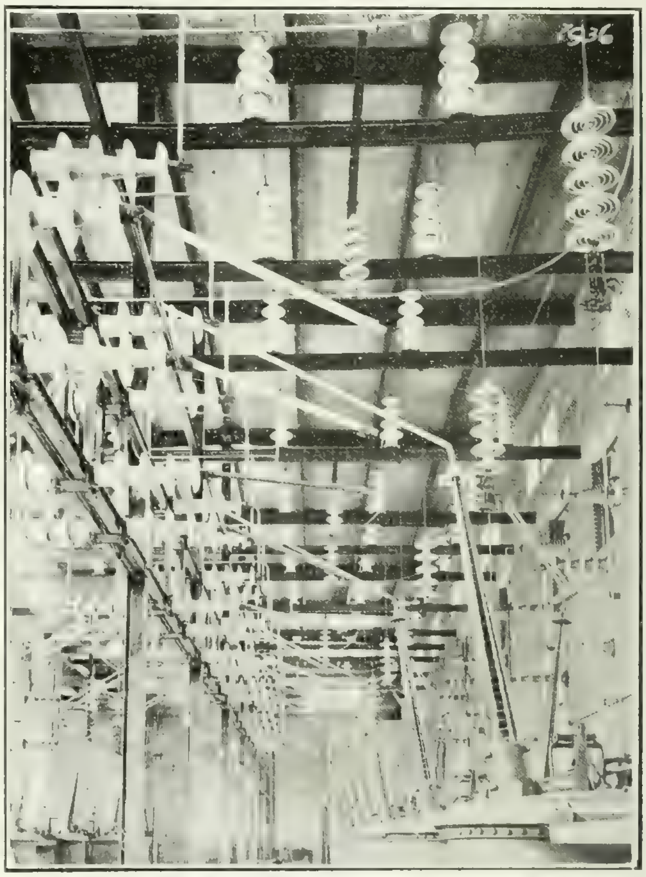

Fig. 28.—General View of 110,000-Volt Layout, Dundas Station.

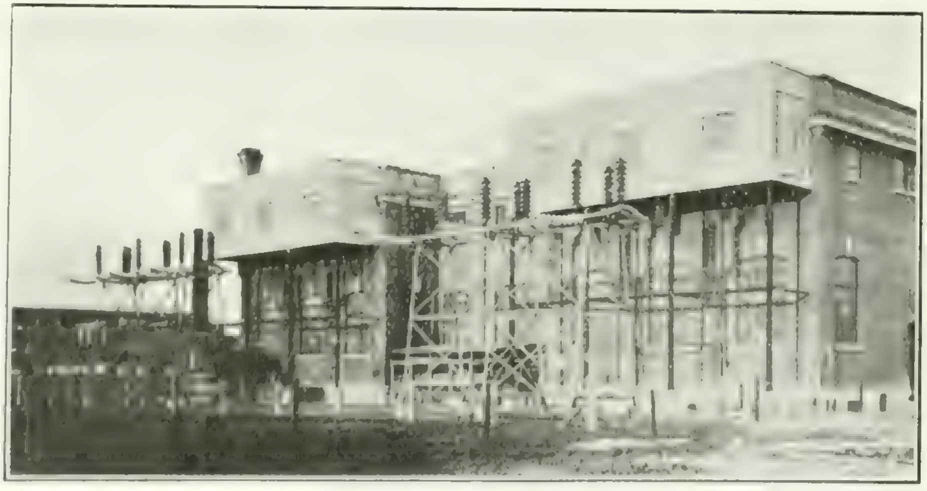

Fig. 29.—Toronto Station.

The transforming equipment consists of two banks of 1250 kv-a. transformers stepping down the transmission voltage to 13,200 volts. The low-tension leads branch and run through the oil switches to two sets of buses, each of which is divided into two parts. The cell work is built with pressed brick walls and concrete shelves. Ultimately, two ring buses will be installed, each being divided into four sections. At the present time there are eight feeders installed, each provided with automatic oil switches for connecting to either set of buses. The oil switches and buses are located in two rows on a gallery while the potential and series transformers are placed in compartments on the main floor immediately beneath the [illegible] [illegible]. The buses are protected by aluminum cell surge protectors. The outgoing feeders to the five municipal substations in different parts of the city leave the building by underground ducts. These municipal stations are located in such a manner that they may be electrically connected in a "loop" circuit.

The city of Toronto is at present installing transformers stepping down from 13,200 to 2,200 volts in the basement of the station, which will be used for city service, mainly to supply energy for the factory load of the city, a large part of which is located within one-half mile of the station. (Fig. 31).

9'-6"
Note - 4 bars ½" diam. over oil openings in concrete walls over 2'-6" wide, bars to be 12" longer than width of the opening

Fig. 30.—Transverse Section, Toronto Station.

The control switchboard is located on a small gallery. All 110,000 and 13,200-volt switches are operated from the board. Curve drawing meters are mounted on the feeder panel for recording both the load and power factors.

A concrete pump house has been constructed a few hundred yards distant on the shore of Lake Ontario with an intake pipe extending 500 feet into the lake to provide cold water for cooling purposes. Duplicate motor-driven pumps and a service equipment similar to that at the Niagara Falls station is employed.

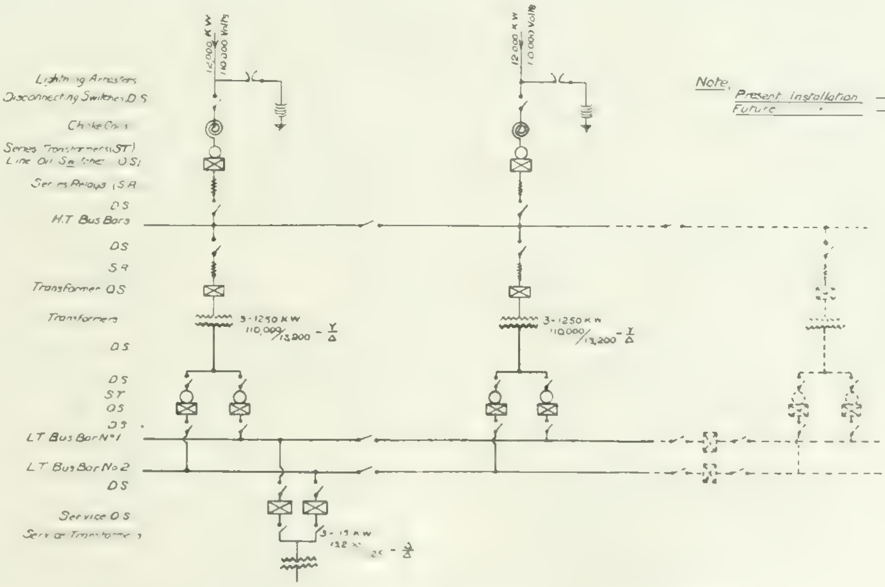

Fig. 31.—Wiring Diagram, Toronto Station.

Loop Stations.—The 110,000-volt equipment is similar in each of the "loop" stations. The lines enter the stations through automatic oil switches to the buses, and pass out through similar circuit-breakers. The incoming and outgoing lines in each station are provided with electrolytic arresters. The transformers are supplied with current at high potential, from the buses through automatic oil switches. Disconnecting switches are installed on either side of the oil switches, except on the transformer side of the transformer oil switch.

Each station is equipped with a bank of three single-phase 750 kv-a. oil-insulated, water-cooled transformers and also a spare unit available for use in case of an emergency. The low-tension winding potential is 13,200 in every case with the exception of Preston, where the greatest transmission distance is only six miles, and 6,600 volts potential was adopted for distributing purposes. All transformers are supplied with taps for both 6,600 and 13,200 volts.

The low-tension equipment is similar, and the general arrangement the same in all stations, the only difference being in the number of outgoing feeders. All feeders are equipped with automatic, hand-operated oil switches, disconnecting switches, switchboard panels containing indication and recording meters, relays and handles for operating the switches, and protected by electrolytic lightning arresters.

Provisions were made for six outgoing feeders at each of the present stations. Preston, Berlin and

Woodstock are now utilizing their full complement of feeders.

The service equipments, both electrical and mechanical are in general the same as those employed in the stations previously described, except that no storage batteries or motor generator sets are required because the switches are hand-operated. Duplicate water-pumps are provided to circulate the water employed to cool the transformers except in instances where city water service has been secured.

The spare transformers in any of these, as well as in London and St. Thomas stations, may be quickly connected in a bank in place of a disabled one.

London Sub-Station.—This station is a "loop" station with a branch line running off the main bus. The high-tension equipment is practically the same as that in the other "loop" stations just mentioned, with the addition of an oil switch connecting the buses and line supplying St. Thomas. There are four 110,000-volt and six 13,200-volt electrically operated oil switches, and three 1,250 kv-a. transformers installed in the station. A spare transformer is also provided for use in case of emergency. Four 13,200-volt feeders supply energy to the city of London's distributing station and to the provincial asylum.

St. Thomas Sub-Station.—This station will ultimately be a "loop" station, although it is a terminal station at the present time, and consequently has no 110,000-volt outgoing line equipment. The building, however, is constructed similar to the other standard "loop" stations.

Operation of System.

The Dundas station, because of its location, was designed as controlling station for the entire system. The chief operator and his assistants, who act in the capacity of load despatchers, are located at this point and by means of the private telephone system are able to keep in constant communication with the operators at the other stations. The switching equipment which has been provided makes it possible to cut out a section should trouble occur and yet supply energy to all the stations on the high-tension line. Since the Niagara station is the source of supply for the entire system it is essential that communication be maintained between this and Dundas station at all times, and a duplicate telephone line has, therefore, been provided.

Energy was first delivered to the Niagara transforming station for testing purposes on August 25th, 1910. The load and power factors of the system are both fairly high, while the voltage regulation is less than 2 per cent.

◆

THE PRODUCTION OF PIG-IRON IN THE ELECTRIC FURNACE.*

Extensive experiments have been carried out from time [illegible] "electrically fired" blast furnace. The coal supply of these countries [illegible] electric power being available, the subject has become of [illegible] Trollhattan, the site being particularly suitable by reason of [illegible]

Principles Governing the Design of the Furnace.—The following special considerations had to be carefully taken into account in the design:—

1. Working with high temperatures produced electrically, means must be taken to obviate current losses through the linings of the furnace, particularly because the materials in question increase in conductivity with the rise in temperature.

2. The construction must make allowance for decrepitation of the walls due to the intense heat and the contact with the charge.

3. The hot substances in the hearth must not exert pressure on the electrodes, as, in such a case, only very low voltages could be employed. This would, of course, necessitate excessive dimensions of electrodes and connections.

4. The combustible material does not "burn" in the ordinary sense of the word; therefore, to obtain uniformity in the quality of the products, the hearth must be made of large dimensions and must also act as a mixing chamber.

In order to fulfil these conditions, the hearth (K in Figs. 1 and 2) is made in the shape of a large crucible with a domed cover. The electrodes pass through this dome but do not come into actual contact with the hot substances in the hearth. The body is so designed that the descending substances discharge into the hearth as through a cone, leaving a clear space above the level of the slag, and surrounding the electrodes. The usual method of regulating the heat by raising or lowering the electrodes, for constructive reasons cannot be adopted here, and for the first time the heat regulation has been achieved by independent regulation of the voltages on each of the two phases of the current employed.

Construction of the Furnace.—The furnace is designed to produce 7,500 tons of pig-iron during 11 months of the year, or about 23 tons per diem. The following data were established as basis for calculation:—

(a) 1 cb. m. of wood charcoal weighs 150 kg.

(b) To produce 3 kg. of iron, 1 kg. of charcoal is required.

(c) 1 kg. of pig-iron can be obtained from 1.725 kg. ore.

(d) Specific gravity of ore employed = 2.5 kg./cu.dcm.

(e) Half of the mineral charged will fill the interstices between the pieces of charcoal of the same charge.

(f) The daily amount charged is 1.55 times the cubic contents of the furnace.

To produce 23 tons of pig-iron under these conditions, 51 cb. m. of wood charcoal must be mixed with 7.9 cb. m. of ore—say 59 cb. m. in all; this, divided by 1.55, gives a capacity of 38 cb. m. capacity for the furnace, divided roughly into 13 cb. m. for the hearth and 25 cb. m. for the body.

The building which contains the furnace covers a piece of ground 24 m. x 15½ m. The overall height of the building is [illegible] m. and the height from the ground level over the throat of the furnace is 13.7 m.

The furnace is composed essentially of two parts, the body C and the crucible or hearth K.

The outer part (shell) of the former varies in thickness from [illegible] mm. at the top to [illegible] mm. round the cone; it also carries all the iron supports for the fire-brick lining. The whole structure is supported on two girders by means of an octagonal channel-iron framework riveted to the shell. Thus the greatest part of the furnace, the dome of the crucible, is relieved of all stress, and independent expansion is possible for each of the essential parts. The joint between them is made with sand. The maximum internal diameter of the body is [illegible] mm., tapering to [illegible] mm. at the throat. The charging cone is actuated by a [illegible] h.p. motor, and the charges of ore and charcoal are raised to the charging stage by a 16-h.p. motor.

---

* [illegible]

The crucible hearth or melting chamber rests on a solid concrete bed, and like the body is encased in boiler plate, which here is 15 mm. thick. At the point where the weight of the dome is taken, the shell is reinforced by a steel band having a section of 200 mm. x 18 mm. The lining of refractory material is covered with magnesia bricks, and the floor of the hearth is formed of magnesia bound with tar. Fig. 3 shows the original section of the hearth, and its appearance after six months' working.

Four electrodes, (E, Figs. 1 and 2) two to each phase of the two-phase current used, pass through asbestos-packed gas-tight openings in the dome, making an angle of 65 deg. with the horizontal. Each electrode is made up of four pieces of carbon, has a total section of 660 x 660 mm. and weighs 1,300 kg. The average loss in weight by burning away is 5 kg. per ton of iron produced, but to this must be added an equal amount rendered unfit for any further use. Outside the crucible the electrodes pass through copper water jackets. Connection with the cable leads is made by cast-steel terminals, which clamp the cables to the carbons.

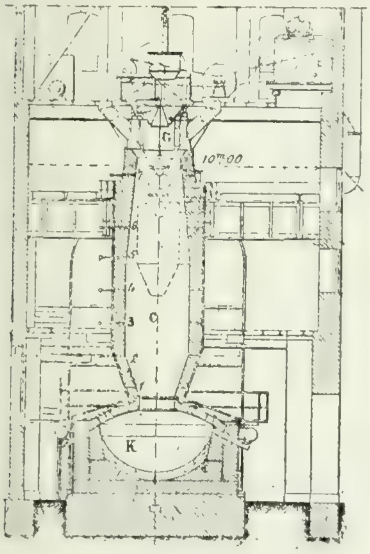

Fig. 1.

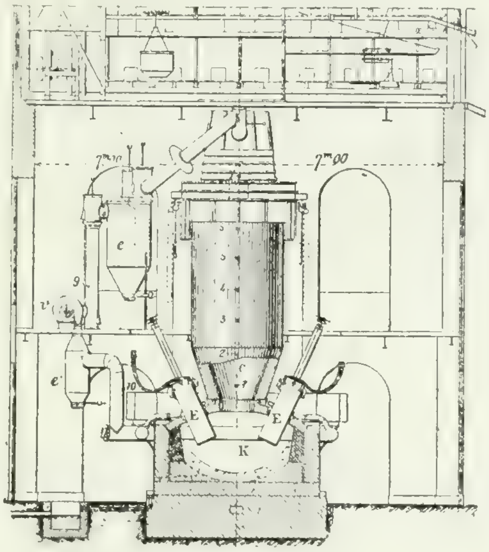

Fig. 2.

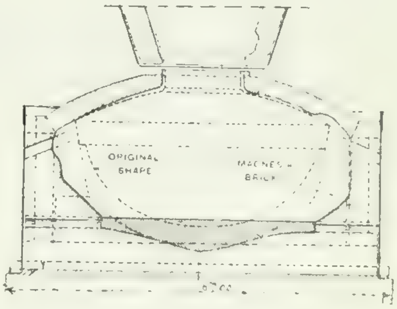

Fig. 3.

A quantity of gas extracted at the throat is drawn through a dust screen by a centrifugal fan, and is blown again into the space which exists between the molten mass and the dome. Four adjustable twyers or nozzles are used to distribute this gas, being arranged at intervals of 90 deg. apart round the crucible. This supply of waste gases into the crucible serves a double purpose: the gases are heated up in the crucible, and give off the absorbed heat as they pass into the upper zones, thus materially assisting the reduction; further, they cool the dome, and thus prevent its too rapid destruction. With gases at 200 deg. C., and containing equal volumes of CO and CO_2, 70 cb. m. per minute at a pressure of 325 mm. water gauge are blown into the crucible by the 8-h.p. electric fan. There are the usual fittings for drawing off the slag and the iron.

Electrical Equipment.—The supply is three-phase at 10,000 volts, and is transformed to two-phase current with a pressure variable in each phase from 50 to 100 volts. From the transformers the energy is led to the furnace by four leads, each lead consisting of six copper strips 200 mm x 8 mm. in section. Each strip, again, is connected to eight cables, each having 185 sq. mm. section; thus 48 cables having a total section of 8,800 sq. mm. are connected to each electrode.

Electric measuring instruments of various kinds are supplied, including platinum and platinum-rhodium pyrometers.

The current varied between 3,000 and 18,000 amperes, with a pressure variation of between 50 and 100 volts per phase. The power used varied considerably, the load ranging from 300 to 2,000 kw.

Conclusion and Results.—Three series of experiments were made by Messrs. Leffler and Nyström, of the "Jern-Kontoret," in the six months referred to, and the results are tabulated below:—

Number of experiment	I.	II.	III.
Mean primary load, kw.	1,319	1,717	1,680
Mean secondary voltage—			
Phase I.	65.2	75	81.9
Phase II.	65.9	83	88.2
Mean secondary amperes—			
Phase I	13,731	13,564	11,922
Phase II.	13,416	11,817	10,406
Kw.-hours per ton cast	2,296	2,481	2,241
Kw.-hours per ton cast, useful work	1,454	1,686	1,595
Kw.-hours per ton cast, losses	842	795	646
Efficiency, per cent.	62.33%	67.96	71.77%
Losses—			
Transformer losses	1.83	2.74%	2.12
Secondary losses (including leads)	3.31	3.83	3.03%
Absorbed by cooling water	6.53%	6.57%	6.53%
Radiation and other losses	26.00%	18.90	16.55%
	100	100	100
Calorific value of waste gases per cubic metre	2,786 cal.	2,892 cal.	2,544 cal.
Of this 80 only can be utilized	2,230 cal.	2,315 cal.	2,035 cal.
Consumption of charcoal in hectolitres per ton cast	25.02	22.88	21.10

The average consumption of charcoal in other furnaces is 62.8 hl. per ton.

In conclusion, it is interesting to note that the most serious incident in the six months' work was an explosion in the crucible due to the rapid descent into the molten mass of a quantity of powdered ore which had not been thoroughly dried.

SOME FALLACIES AND FACTS CONCERNING ENGINEERING WORKS IN GREAT BRITAIN.

By W. A. MARTIN,
Late Assistant General Manager of the Toronto Electric Light Company.

(Continued from last issue.)

Messrs. Willans and Robinson, Rugby.

A few years ago a visitor to any of the electric power supply stations in the United Kingdom would have expected to find in almost every power house long rows of vertical steam engines, all exactly alike, direct coupled to electric generators. The generators in the different power stations would have been constructed by a number of different makers, but the engines would almost invariably have been the then [illegible] Willans central valve high speed vertical engine. The output of each individual unit would generally have been less than 1,000 h.p. and the total power required would have been obtained by running [illegible] units together.

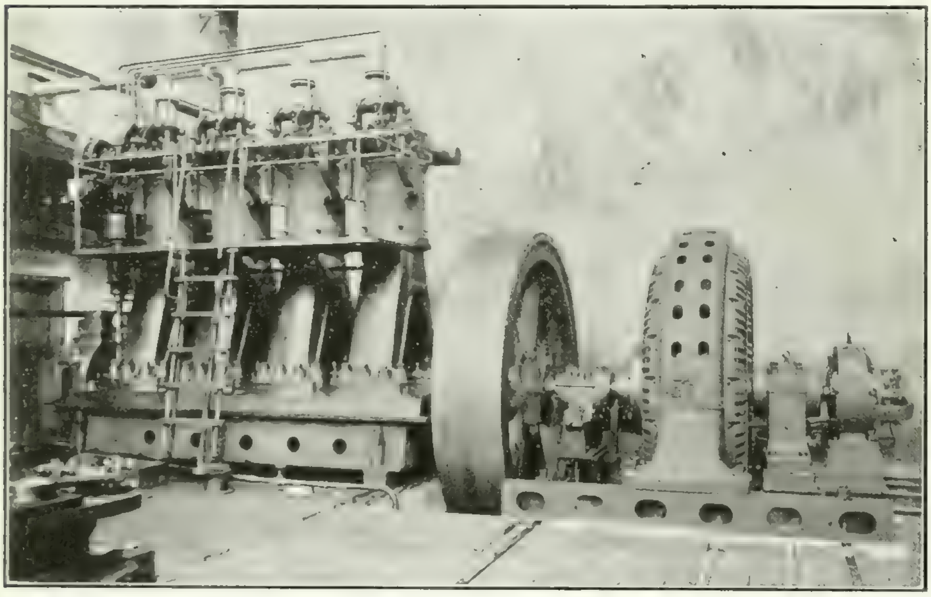

Fig. 6.—200-kw. Diesel Oil Engines Manufactured by Willans & Robinson, Ltd., for the Chilian Oil Fields.

The perfecting of the steam [illegible] compete with the Willans steam tur-[illegible]

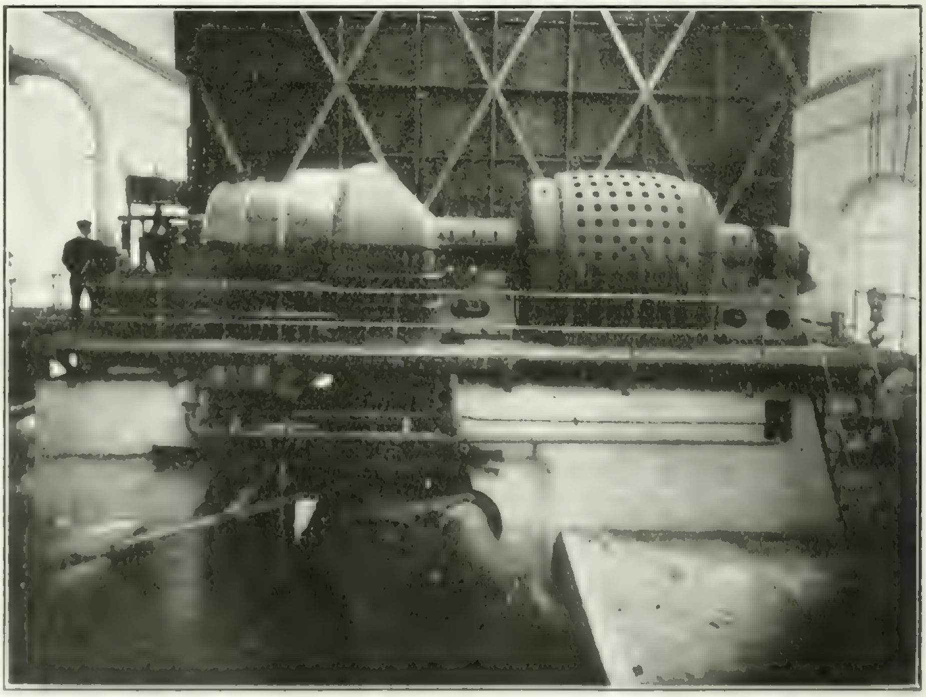

Fig. 7.—8000-kw. Disc and Drum Steam Turbine Built by Willans & Robinson, for the Sheffield Corporation.

[illegible] a source of trouble in steam turbines. Such troubles as were still encountered were due to the excessive unsupported length of the shaft and the admission to the turbine body proper of steam at high temperatures. The firm's latest disc and drum design overcomes these difficulties entirely. It embodies the impulse principle at the high pressure end and retains the reaction principle at the low pressure stages. A further advantage of this design is that it occupies considerably less floor space than the earlier types.

Messrs. Willans and Robinson have recently executed an order for one of their new disc and drum type 8000-kw. turbo generators for the Sheffield corporation electricity department, and through the courtesy of Mr. S. E. Fedden, the city electrical engineer, I was afforded an opportunity of seeing this plant in operation. It appeared to be running perfectly in every respect, and the engineer in charge spoke very highly of its performance, which, he informs me, was in some respects better than called for in the specifications.

The condensing plant is of the surface type with vacuum augmentor and Edwards type air pump, built by the turbine makers.

A 400-kw. set of the maker's earlier design has been working for a number of years, in the same power station in Sheffield with equally satisfactory results.

Messrs. Willans and Robinson are amongst those who believe that the prime mover of the future is the Diesel oil engine. I saw a number of these interesting engines in course of construction at their works. The firm's great experience in building high speed vertical steam engines particularly qualifies them for constructing engines of this type, which calls for specially careful workmanship and the use of the highest class materials. Here again I was struck by the large amount of work being executed for shipment, and was pleased to see steam turbines and Diesel engines being built for Canada.

The illustrations show the Sheffield disc. and drum turbine coupled to a Dick Kerr alternator. The Diesel engine shown is one of four 200-kw. sets sent last year to the Chilian nitrate fields.

Since returning to Canada I have been informed that the Electric Power Company has ordered a Diesel engine of about 600 h.p. capacity for their Oshawa plant from Messrs. Willans and Robinson after very thorough investigation by their consulting engineers, who sent an engineer to Europe for the purpose.

This firm has also, I am informed, recently received an order for a large steam turbine of some 9,000 k.w. capacity for shipment to British Columbia.

Messrs. The Sandycroft Foundry Company.

The Sandycroft Foundry Co., which is probably the oldest established concern of its kind in Great Britain, at their works near Chester specialize in the manufacture of mining machinery of all descriptions, including ore crushers, stamp mills, cyanide plants, winding engines, haulage gear, etc. They have also perfected an interesting alternating current motor known as the "Hunt Cascade Motor," which possesses the valuable property of being able to develop an output approaching its maximum over a very wide range of speeds. The Sandycroft Company have carried out a large number of contracts for complete mine equipment in India, South Africa, Spain, the Australian Colonies, South America and in other parts of the world. They are particularly interested in the prospects of mining developments in Canada, and intend to cater vigorously for this market.

They had a large amount of plant in course of construction at the time of my visit to their works and showed me, among other things, parts of an 8,000-h.p. steam engine they were building for one of the mines in South Africa. I was informed that the shipping weight of this engine, when completed, would be 280 tons.

Messrs. Mather and Platt, Limited.

This well-known firm was established nearly one hundred years ago and has recently built entirely new works on the most up-to-date principles, which are fitted with most modern machinery. They employ somewhere about 3,000 work-people, and the concern is the foremost in the world for the manufacture of machinery for the bleaching, printing, and finishing of cotton cloth; in fact, I was informed that almost all the machinery used in these processes of textile manufacturing owes its origin to them, and wherever cotton cloth is made the name of Mather & Platt is known in connection with the supplying of machinery for the finishing processes.

They are also very large electrical engineers, who have carried through the earliest railway traction work in Great Britain; and I was shown an immense amount of apparatus in course of construction in their electrical shops.

They were also the original manufacturers of the centrifugal turbine pump, now so widely known throughout the world.

Amongst their other departments those for the manufacture of fire appliances and plants for the purification of water are the most important.

A visit to these new workshops impresses one with the idea that the concern is full of enterprise and vigor, and is by no means falling behind in the engineering race, notwithstanding the long time it has been established.

Messrs. Dorman, Long & Company, Limited.

The Britannia Works of Messrs. Dorman, Long & Co., Limited, comprise steel furnaces, rolling mills and constructional and bridge shops. The steel is made by the basic open hearth process and is rolled into sections of all descriptions for use in engineering, shipbuilding, general constructional work and allied trades. The steel plant consists of ten basic open hearth steel furnaces and two large hot metal mixers and all operations in handling the material required for the manufacture of the steel are controlled by modern overhead electric cranes and charging machines. The output of ingots from this plant is approximately 20,000 tons per month. The hot ingots are delivered direct into the soaking pits of four rolling mills. The 32-in. and 31-in. reversing mills are steam-driven and the equipment is perhaps notable for the three-cylinder type of marine engine driving the finishing mills which is of 16,000-h.p. capacity. The entire mills are equipped with fast traveling electric cranes covering all operations. The output of sections of all kinds from these two mills is approximately 14,000 tons per month. The company have recently put into operation a new exhaust turbo station for the generating of electricity. The exhaust from the steam-driven mills is delivered through steam accumulators to four 1280-kw. mixed-pressure turbo-generators. This power station is of a most up-to-date and modern construction. The current from this station, in addition to driving two electric mills, supplies the power for the whole works. The electric mills consist of one 18-in. reversing mill and one 11-in. three high direct-driven mill. The sections rolled in these two electric mills are rounds, squares, flats, angles and bars of all kinds required in the engineering and shipbuilding trades. The output of these mills is approximately 6,000 tons per month.

The constructional and bridge department is the best equipped of its nature in Great Britain and has no equal on the Continent of Europe. The shops are 540 feet in length and consist of four bays with several lean-to buildings for special work. Each bay of the main shop is served by fast-traveling overhead electric cranes. Many novel features and improvements have been incorporated quite recently, all of which have independent motor drives. The shops are equipped with pneumatic and hydraulic appliances and are entirely closed in and well lighted. The output of bridge and building materials is approximately 3,500 tons per month. The current for both lighting and power purposes is generated at the company's central power station above mentioned.

At the Clarence Steelworks of the company the melting shop department consists of a gas-heated metal mixer capable of holding 400 tons of molten metal, and nine open hearth steel furnaces, of which eight are of 50 tons capacity and one of 60 tons. The bulk of the steel manufactured at these works is for special purposes in various carbons ranging from 0.08 per cent. to 1.5 per cent., a few of the specialties being soft steel for high conductivity wire and locomotive tubes, and hard steel for saws, picks, wire ropes, files, edge tools, etc. The ingots are taken from the steelworks and placed in coal and gas-fired soaking pits by two five-ton electrically driven cranes, from whence they are taken to the rolling mills, which are three high and consist of three trains of rolls, viz., cogging, roughing and finishing, the diameter of all three mills being 32 inches. The product of these mills is principally high carbon steel rails and billets, bars and slabs for the purposes above described.

A 100-ton electrically driven overhead crane is provided for changing rolls, so that the mills can be readily changed to roll various sections. Duplicate standards are also provided and a set is always ready fitted up with rolls and guides for the next section to be rolled. The blooms are cropped and cut to the required lengths by a pair of specially designed hydraulic shears. The blooms then go on to electrically driven lifting-tables which move them to each pass in the rolls. When the finished bar is rolled it is taken by live rollers, also electrically driven, to the hot saws. There are three "hot banks" and two saws, the second one being placed 291 feet from the rolls.

The wire department consists of wire rod rolling mill, wire drawing, annealing and galvanizing mills. The product is chiefly high-grade wire rods and wire for wire ropes. The department carries on a large export trade in wire rods and rope wire.

The sheet works department comprises eight sheet mills, four galvanized baths, eighteen puddling furnaces, and two ball furnaces. The capacity is 25,000 tons per annum of finished sheets, mostly iron, for roofing and other purposes.

The total number of men and boys employed throughout all the works is 4,500.

Dorman, Lang and Company are already catering for Canadian business and I was informed that they were manufacturing several sizes of structural steel beams in what is known as American sections and had shipped some two thousand tons of structural steel to Canada in the past year.

Messrs. Reavell & Company.

Messrs. Reavell & Company, of Ipswich, have concentrated their attention upon the perfecting of air compressors for all purposes. Their leading specialty is a 4-cylinder machine in which the cylinders are arranged radially in a [illegible] a perfectly even turning effort [illegible] efficiency, [illegible] in the small space taken up.

They are [illegible] used for directly coupling to electric motors.

There should be a considerable demand for compressors [illegible] where cheap electric power can be [illegible] have been installed in this country.

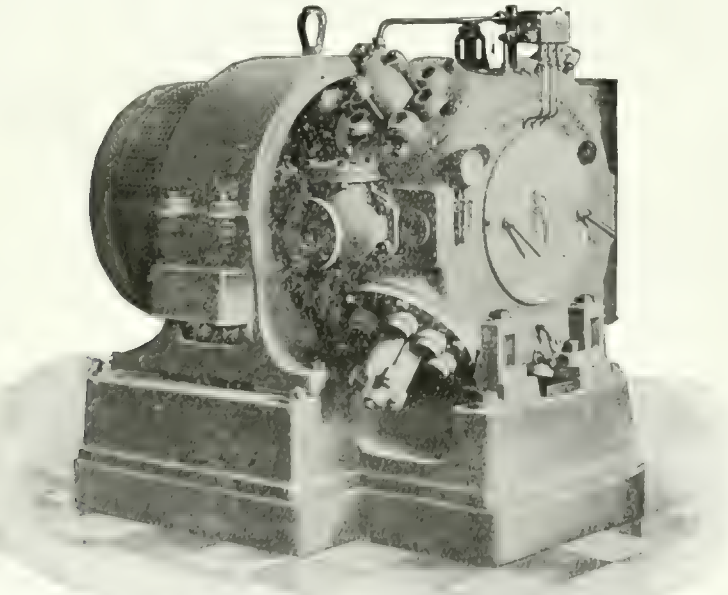

Fig. 8.—Four-Cylinder Reavell Air Compressor, Manufactured by Reavell & Co., Ipswich, Eng.

Messrs. Reavell also make ordinary straight line compressors, and for very large capacity plants the vertical type of compressor. I was particularly interested to see a large number of special compressors of very high pressure in course of construction for use with Diesel oil engines.

Ransomes, Sims & Jefferies, Limited. The Orwell Works, Ipswich, England.

This great business was established as far back as the year 1789 by Mr. Robert Ransome, and its history has been one of steady and continuous growth and expansion. At the present time about three thousand men and boys are employed at the Orwell Works.

Not only in Great Britain, but throughout the Continent of Europe and in all parts of Asia, South America, Africa and Australasia, where machinery can be used, is the name of Ransomes, Sims & Jefferies, Ltd., famous for the best steam engines and threshing machines the world has ever seen, as well as for stationary engines, ploughs, implements and the other specialties named.

The Orwell Works cover about thirty acres and consist of a group of four separate factories, comprising:—

(1) Engine and boiler works, foundry and smith shops.
(2) Threshing machinery and tea machinery works.
(3) Plough and implement works.
(4) Lawn mower works.

The various shops are well laid out and lighted by a first-class system of high-pressure gas, and in winter time warmed by steam for the comfort of the workmen.

The works are equipped with remarkably fine installations of the most modern machine tools and labor-saving appliances of all kinds, enabling the highest possible degree of accuracy to be attained in the production of work. The machine tools are so arranged as to ensure a continuous flow of work from the entrance of the raw material to the assembling and erecting shops.

Standardization and interchangeability of parts are carried to a high art in the Orwell Works, Ransomes, Sims & Jefferies, Limited, fully recognizing the great importance of this matter in connection with the supply of extra parts for their manufactures. Purchasers in distant countries have always the assurance, therefore, that no difficulties will occur in the adaptability of duplicate parts subsequently ordered.

In the threshing machinery works, where timber is necessarily largely employed, the most perfect system of wood-working machine tools prevails, thus ensuring rapidity of production combined with the highest degree of accuracy. Powerful electrically driven fans are provided in this department, which, by means of a system of exhaust pipes, extract all dust from the wood-working and grinding machines, thus maintaining the various floors in a clean and pure condition, conducing greatly to the comfort of the men. All threshing machines are thoroughly tested before leaving the works, being driven during the trial by electric motors.

The numerous types of threshing machines manufactured by the company are such as to fully meet the many different conditions of all the agricultural countries of the world, the threshing machines being equally suitable for dealing successfully with practically all kinds of cereals grown in both eastern and western countries. For countries where the threshed straw is utilized as food for animals, Ransomes, Sims & Jefferies' threshers are provided with a special apparatus, which reduces the straw to very short lengths, bruising it at the same time, thus facilitating mastication.

The plough and implement works, the largest factory of its kind in Great Britain, is one of the latest additions to the Orwell Works. This department comprises immense and magnificently laid out shops on the ground level, where thousands of types of ploughs and implements destined for all the agricultural countries of the world may be seen in various stages of construction.

The lawn mower works consist of a very perfect self-contained establishment, where the most modern and approved system prevails for the rapid, accurate and economical manufacture of motor, horse-power and hand-power lawn mowers of all kinds, together with well equipped stores where enormous quantities of these machines are kept in stock.

The Orwell Works include extensive stores for engines, threshing machines, ploughs and implements of various types, this being a matter of the highest importance in connection with prompt deliveries.

Electric cranes are in use in all the chief departments of the works, and the larger machine tools are driven independently by their own electric motors, which, together with the cranes, are supplied with current generated in the company's power house.

I visited a number of other engineering works while in the Old Country, notably those of Sir William Arrols & Company, Glasgow, the builders of the Forth Bridge; the Electric Construction Company, Wolverhampton, manufacturers of electrical apparatus; Callender's Cable and Construction Company, Erith, manufacturers of lead and paper insulated cables, anti-friction metals, alloys etc., and Galloways, Limited, Manchester, manufacturers of large gas engines, rolling mill engines, boilers and pumping plant, but space will not permit of my describing them here.

My entire visit convinced me that Great Britain is still able to hold its own as the premier manufacturing centre of the world and that in the design and manufacture of engineering apparatus and allied appliances is keeping quite abreast of the times.

I would strongly advise Canadian buyers who are contemplating making any large purchases of engineering plant to give full consideration to British-made goods before purchasing, and preferably to pay a visit to the works of some manufacturer in Great Britain who has specialized in the particular line of machinery required. Where buyers take the trouble to do this it almost invariably results in the purchase of British-made goods. Such a visit cannot but inspire confidence in the mind of the buyer that he is being shown methods and practices which can have but the one result, viz., the turning out of apparatus of the highest quality.

◆

A double roof of reinforced concrete is one of the features of the ice palace recently built in Hanover, Germany. The barrel arch of this roof, which, as a span of about 69 feet, is supported on nine reinforced concrete rafters, and the thrust is taken up by the rods placed beneath the floor of the structure and anchored to the concrete of the haunches. The panels between the rafters form a thin interior reinforced concrete ceiling, and, being a continuation of the compressing slabs of the barrel arch rafters, they form virtually a complete unit. The second reinforced concrete roof, which rests on the square rafters of the barrel arch, is of heavier construction, and is covered with a layer of waterproofing felt. The air confined between the two roofs acts as an insulating material, and is said to reduce largely the influence of outside temperature

SOME MECHANICAL CONSIDERATION OF TRANSMISSION SYSTEMS.*

By T. A. Worcester.

In any transmission system each of its elements, the supporting structures, the insulators and conductors, has a vital mechanical function and on each may rest the success or the failure of the system. In the early days of high voltage transmission these points were not given due consideration and there were many cases of the destruction of lines due to washouts, sleet and wind storms and frequent breakages of wires due simply to contraction at low temperatures. During later years, however, engineers have profited by these experiences and a greater study has been made of the details of mechanical construction, resulting almost entirely in the elimination of disasters except in cases of most unusual and severe conditions.

The purpose of this is to review in a general way the stresses which must be considered in the various elements of a transmission system and to point out some of the means which have been resorted to to meet certain special conditions. Consideration will be given chiefly to steel tower structures since they are by far the most important type of support for higher voltages. The wooden, steel and concrete poles have their field in the lower voltage range where they are able to compete against the built-up structure.

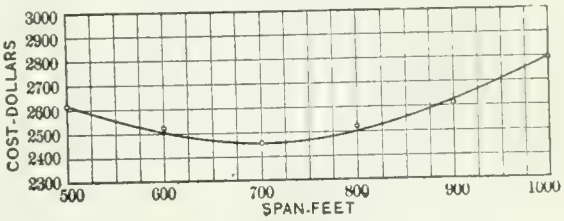

Fig. 1.—Cost per Mile of Towers and Insulators Erected.

Stresses.—The stresses which a tower must be designed to withstand are (a) those acting in a vertical direction, due to the dead weight of the conductors and insulators, plus an allowance for ice covering; (b) in a horizontal direction at right angles to the line, due to wind pressure; (c) in a horizontal direction parallel to the line due to wire breakages. All of these loads are applied at the ends of the cross-arms except a portion of (b) which is distributed over the entire tower.

The vertical load depends on the size, material and number of the conductors and ground wires, length of span and thickness of ice coating; the horizontal load at right angles to the line depends on these same elements which determine the exposed surface, and the wind velocity; the horizontal load in the direction of the line depends on the size and number of conductors, the amount of ice and the number of wires which may break at any one time. Each of these governing factors will be briefly discussed.

The size of conductor depends on electrical considerations except where the length of span is the governing feature.

The length of span, except in river or gorge crossings, is dependent upon the designer and must be chosen so as to give the line the least cost. As the span increases, the number of towers and insulators per mile decrease, but on the other hand the height of the towers must be increased to care for the greater sag and at the same time they must be made proportionately stronger and heavier to care for the greater loads per span. The effect of these changes on the cost of a line is shown by the curve, Fig. 1. The length of a span affects the loads in the vertical direction and in the horizontal direction across the line and not that parallel to the line, since the latter is governed by the size of the conductor, it being necessary to adjust the sag so as not to exceed the safe stress for the wires.

---

*A paper presented to the American Institute of Electrical Engineers, May 17th, 1912.

For every size of conductor there is a practical limit of the length of span beyond which the sags and height of tower becomes excessive and there is danger of the wires swinging together. For the smaller sizes of conductor this limit is quite low (300 ft. (91 m.) for No. 4 cable) and in many cases it will be found more economical to increase the size of conductor so as to permit using a greater span. The following tabulation illustrates this:—

	Size of Conductor	Span feet	Sag feet	No. of towers per mile	Cost of towers and insulators per mile erected	Cost of wire and freight per mile	Total per mile
Case I.	No. 4 B.&S.	300	10.5	17.6	$3080	$322	$3402
Case II.	No. 2 B.&S.	360	10 5	14 7	2570	514	3084
					Saving per mile. .		$318

These figures are based on the assumption that the same towers and sags would be used in both cases, giving the same clearance to ground. The sag in Case I is the minimum sag at which wires may be strung on the basis of 0 deg. Fahr., 8 lb. (3.6 kg.) wind, and ½ in. (1.27 cm.) sleet and with these same conditions and sag the span for No. 2 wire is calculated and found to be 360 ft. (109 m.) With this tower spacing and No. 2 cable the cost of the line is $318 less than with No. 4 cable and 300 ft. (91 m.) span. It is allowable to assume that the same towers can be used in the second case as in the first since the lightest tower which it is practicable to build would be sufficiently strong for the second case. However, it would be possible to put $20 more into the cost of each tower and still have the cost of the second line a trifle less than that of the first and the gain would accrue from the electrical advantages of the larger size of conductor.

A span of 360 ft. (109 m.) is not necessarily the most economical span for the No. 2 conductor. Further calculation indicates that a 500-ft. (152 m.) span could be used with only a very slight increase in the cost of the towers. This limit cannot be extended beyond 500-ft. (152 m.) even though the line with greater spans would have a less cost. Here again the limit depends on mechanical considerations rather than on costs and is governed by the danger of lashing together of the wires in gusty winds.

In long spans over rivers, etc., the standard main line towers and conductors are frequently used. This practice may be permissible in some instances where the spans are not very much greater than normal but when the towers have been designed to closely meet the demands of the standard spacing it becomes dangerous to use them for any appreciably longer spans. It is advisable in these instances to use dead end anchor towers with strain insulators and thus isolate the crossing span and prevent any trouble in other parts of the line from [illegible].

For such long spans it [illegible] necessary to use conductors of greater mechanical strength than are used in the main part of the line and the supporting structures must likewise be made correspondingly stronger. Too great care [illegible] should be used in the design of the steel work.

Ice and Wind.—The amount of ice which will form on [illegible] will probably never be settled to the satisfaction of all concerned. However, the various engineering bodies have about agreed that it is safe to consider ½ in. (1.27 cm.) ice in conjunction with 8 lb. (3.6 kg.) wind pressure and 0 deg. Fahr. as the worst combination of conditions likely to occur in the United States. It is conceded that there have been thicker formations of ice and greater wind pressures, yet the probability that they will occur simultaneously and with low temperature is so remote as to make it seem unnecessary to consider them. There is little doubt, however, that those engineers who have experienced destruction of their lines by sleet and wind storms will never use anything but the most conservative allowances. For spans crossing rivers, highways or railroads more liberal allowances are always made, the standard being ¾ in. (2 cm.) ice, 11 lb. (5 kg.) wind and 0 deg. Fahr.

Ice and wind on the cables work together to increase all of the loads on a tower structure; the vertical load and the horizontal load in the direction of the line, by giving increased weight to the conductor, and the horizontal crosswise load by giving greater surface for the wind to act upon.

Wind on Towers.—There is a great difference of opinion as to just how much wind pressure shall be allowed on the tower itself. It is certainly not sufficient to base this allowance on the same assumptions as are used for the conductors. Those assumptions are for wind velocities likely to occur simultaneously with heavy loading of ice and low temperature. Greater velocities may occur independent of these last factors. It is, therefore, advisable to allow for at least the highest recorded value. This value, as indicated by the Government anemometer is very nearly 100 mi. per hr., which corresponds to an actual velocity of 76.2 mi. per hr. and a pressure of 23.2 lb. (1005 kg.) per sq. ft. (=0.09 sq. m.) ($0.004 \times V^2$ for flat surface). The government anemometer records the velocities only at intervals and does not give all instantaneous values and these instantaneous values may be somewhat greater than those at the moment the record is taken, due to the gusty character of winds. It has been estimated that these gusts cause velocities 50 per cent. greater than those which are recorded. Another feature enters, however, to somewhat counterbalance this effect, viz., the height above the earth surface. The anemometer records are taken well above the earth surface, while transmission structures are seldom higher than 75 ft. In consideration of these variables and uncertainties it is not possible to give one value of pressure to be used on all lines. A safe range of pressure though would be from 20 to 35 lb. (9 to 16 kg.) per sq. ft. (=0.09 sq. m.) depending on the general character of the country which the line traverses, i.e., whether it is exposed to sweeping winds or protected.

It will usually be found that the maximum wind pressure acting on the bare towers and wires will have a greater overturning moment than that caused by the maximum wind assumed to accompany ice formation, acting on the ice-coated wires and towers, i.e., the greater pressure due to the higher velocity of the wind, even though exerted on a smaller surface, will overbalance the less pressure acting on the greater surface. For this reason the side pressure on towers should be figured for both conditions and the design should be based on the loads caused by the worst of the two.

In calculating the wind on the towers the entire projected area of the two lateral faces should be used as the surface over which the wind acts.

Wire Breakages. The most serious stresses which a transmission tower is called upon to withstand are those due to the breaking of conductors. Lines are put up with a view of not having the conductors break but there are certain unavoidable conditions which frequently produce breaks. The most usual of these are [illegible] burning of the conductors due to short circuits or grounds started by lightning, large birds, swinging together of wires, etc., or through malicious intent; (b) breaking of conductors due to crystallization or fatigue of the metal produced by kinking during erection or by insufficiently rounded edges of cable clamps and (c) by overloading of conductors during extreme conditions of temperature, wind, etc.

The causes in (a) have been overcome to a great extent by the use of various devices, principally the arcing ground suppressor, the ground ring and metal sleeve. The swinging together of conductors occurs only when light conductors are used in too long a span where they will be likely to lash in the wind. Ordinarily in well designed spans the wires swing in unison so that there is no danger of their coming together.

The breaking of wires due to kinking is frequently not given due consideration and many lines erected by careless workmen have suffered from this cause. The elasticity and strength of the metal on the inside of the bend is decreased enormously by a short bend and when the wire is straightened out and drawn taught by frequent strains in the line it will finally weaken to the point of rupture. Likewise, many breaks have been caused by repeated bending of the conductor at the wire clamp on the pin type of insulator. The localization of the stress by a hard metal clamp finally makes the metal of the conductor brittle and rupture occurs well below the average tensile strength. A clamp may have well rounded edges and still cause trouble. It is the rigidity of the clamp as well as too sharp an edge which is harmful.

When all of the wires of a transmission line are intact there is no pull on the towers in the direction of the line (i.e., on the intermediate towers, not the dead end or other special structures). As soon, however, as a conductor is broken the strain which it took to cause the break is thrown on the adjacent towers. Obviously, therefore, the maximum load which the cross arms must stand in the direction of the line is equal to the tensile strength of the conductor which is used. For the smaller sizes of conductor this rule is usually observed but for the larger sizes less liberal allowances are usually made. It is customary with the larger sized conductors to allow for a stress equal to one-half of the ultimate strength of the cables. This value is chosen since it is the maximum safe working stress, above which the cables are likely to stretch permanently.

With the suspension type of insulator the full length of an insulator string is thrown into the line when a break occurs and the strain in the conductor and on the cross arms is greatly reduced. But little consideration should be given to this fact, however, since there is a severe jerk when the insulator is drawn to its new position and the effect on the tower is not less and may be more than occurs when the pin type of insulator is used.

A question which naturally arises is how many conductors may break at any one time. This depends to a large extent on the cause of the breaks. If due to lightning or large birds it is probable that not more than one or possibly two conductors would break; but if due to poorly designed wire clamps, injury of wire during erection, or to excessive sleet and wind, it is conceivable that all might break. It is very rare, however, for all of the conductors to break, and further, it is hardly practicable to make such an assumption when considering main line towers since it would raise the cost of the line to a prohibitive value. It is usual to compromise by allowing for the breakage of only two cables of a three or six conductor line and to safeguard the system by interposing anchor towers at frequent intervals. These anchor towers would be capable of withstanding the strains due to the breakage of all of the cables and would thus divide the line into isolated sections so that any trouble in one could not be communicated to the other.

In the rigid type of tower practically all of the stress caused by the breaking of several conductors is cared for by the tower itself, i.e., the movement of the top of the tower is not sufficient to permit an even distribution of stress between the unbroken cables of the damaged span and those in the adjacent spans. With the flexible type of tower, however, the effect is different. The tower is designed to be rigid in the plane across the line and flexible in the direction parallel to the line so that it will bend and allow an even distribution of stresses in the adjacent spans. For instance, consider a three-conductor system with one ground wire and assume that each cable has an ultimate strength of 6,000 lb. (2,721 kg.) and is strung to have a tension of one-half of its ultimate strength under the worst conditions likely to occur, and assume that these conditions prevail. Suppose that one of the conductors has been injured or is defective and that it breaks under this load. The tops of the towers on either side of the break will be pulled over by the four cables in the next span until the total tension in them would be just balanced by that in the remaining conductors of the damaged span. The tension would amount to very nearly 12,000 lb. (5,443 kg.), i.e., 4,000 lb. (1,814 kg.) per cable or 33 per cent. more than the allowable stress. This load would not break the cables but it would stretch them beyond the elastic limit and permanently weaken them.

Suppose that two cables had broken instead of one. Each of the remaining two would be strained with nearly 6,000 lb. (2,721 kg.), an amount almost equal to its ultimate breaking strength. The stress would not be quite 6,000 lb. because the tension in the adjacent spans would decrease rapidly as the cables in the damaged span are stretched to greater length. However, the example serves to illustrate that it is necessary to use very much greater factors of safety in stringing conductors in a flexible tower system than would be used in a rigid system.

Foundations.—The foundations of a tower are of prime importance, yet under average normal conditions they offer but a small problem. In ordinary straight line work, over fairly level country, where the soil is hard or rocky and where the smaller sized conductors are used no special foundations are necessary; the ground stub with cross piece or foot may simply be buried in the ground with a little rock filler and if the spread of the tower legs is normal there is little to fear from tilting. With the larger sizes of conductor and longer spans the overturning moment frequently reaches such proportions as to make it advisable to use concrete foundations and thereby eliminate the need of spreading the tower legs an excessive amount. When towers must be placed where the soil is loose or marshy or where they may be endangered by floods or landslides it is essential that special consideration be given to the design of their foundations. It may be necessary to resort to any one of several types of construction; steel or timber piling, crib work, rock filling or concrete, or a combination of two or more of these. Fig. 4 shows one of the best types of foundation, used to meet a very special condition where it was necessary in order to gain entrance to a city to extend the right-of-way along the lake front and place the tower footings in the water.

Angle, hillside and anchor on long spans present serious problems from the foundation standpoint and must be carefully and liberally designed so as to allow no motion or slip whatever. It frequently pays to make a long detour in order to avoid bad hillsides or crumbly crests.

It must be remembered that a very slight tilt at the base of the tower means large displacement at the top which may exert considerable extra tension in the conductors and in the case of the suspension insulator may bring the conductors dangerously near the tower.

Factors of Safety.—In the design of all mechanical structures it is customary after assuming certain conditions of loading to allow a factor of safety; in other words, to design the parts so that their ultimate strength will be several times their assumed loading. The amount of this factor of safety depends on (a) the character of the load—whether steady, intermittent, or otherwise—(b) on the knowledge one has relative to the amount of load; (c) on the ease or difficulty of calculating the structure to care for the assumed loadings; (d) on the possibility of faults in construction and (e) on the risk to life and property. In a transmission structure the load is intermittent and reversing and our knowledge as to its amount is not definite. These features tend to demand a relatively large factor of safety. However, this tendency is more than counterbalanced by the facts that it is not difficult to calculate the stresses when a definite load is assumed, that the chance for faults in manufacture are but few and that the risk to life and property is a minimum.*

Another feature which makes it possible to use a small factor of safety is that a sample tower may easily be tested with the assumed loadings and with ultimate breaking loads. obviously if a factor of safety is used which will permit the tower to be strained with the assumed loads without being permanently deformed then such factor of safety will be satisfactory, provided the assumed loads correspond with the actual loads. The factor of safety for these conditions would be two if it is considered that the elastic limit of the metal is one-half of its ultimate strength. Many transmission towers have been built on this basis with a consequent saving in the cost of the line. On the other hand more conservative engineers have used values three and even four, these higher values being chosen to care for the uncertainty of load conditions. In one line recently built a factor of safety of 4 was used for all of the main line towers and three for all the strain or dead end structures. This at first sight seems illogical, but it is justified, since the strain towers are figured for a very definite condition, i.e., of all cables being broken in one span and with a maximum load of wind and ice on all those in the next span; whereas the intermediate towers are figured on an indefinite assumption; i.e., of having only two cables break while the others are heavily loaded. The use of these large values, however, makes the cost of the line excessive and for this reason it is common practice to use smaller values, two, two and one-half, or three for the intermediate towers and three or three and one-half for the strain towers. With this arrangement the main part of the line will be safe except in case of some unusual condition which produces worse loads than those assumed and in event of such an accident the strain towers will prevent the trouble from travelling to the next section of the line.

For the conductors themselves a factor of safety of two is [illegible] which [illegible] greater allowance is made for ice and wind than in other parts of the [illegible]

Flexible Towers. [illegible]

in using such a system in preference to the six-conductor single tower system, the principal ones being that there is less liability to complete shut-down in case of accident to a tower and that there is greater safety for linemen when repairing damaged towers, conductors or insulators. The reason for the present limited use of double tower lines is the high cost of such a system when made up of the rigid type of tower. If engineers would look more into the possibilities and cost of the flexible structures there would undoubtedly be a more general use of double tower lines.

THE FIRE HYDRANT.*

By C. W. Wiles, Delaware, Ohio.

In setting hydrants at least 6 in. of broken stone or brick should be placed at the bottom of the hydrant, and for at least 6 ft. along the supply pipe. Of course, if the hydrant is set in gravel or sandy soil this is not so necessary, but it will do no harm and may prevent trouble at some time.

In order to facilitate examination and make easy repairs, a gate-valve should be placed on each hydrant. Often this will save shutting off the supply from several streets.

Inspect carefully all hydrants, at least in the fall, before cold weather comes on, and again in the spring. First see that they are empty; if not, see if they have been properly closed. Often the rubber packing valve is defective and should be removed. Sometimes stones get between the valve and the seat, so that no amount of pressure will make it tight, even if there is no water in the hydrant chamber. It is well to test a leak at the valve by listening at the nozzle, or applying an aquaphone to see if there is not a small leak which escapes through the waste. Roots and grass often grow in the bottom of hydrants and prevent drainage.

If, upon examination, the hydrant is found empty and no apparent leakage at the valve, it is well to blow lightly to remove any sediment or mud that has accumulated in the branch supply line, and then close down and watch through the nozzle for it to drain. If all is in proper order, it should empty in five or ten minutes. If it does not, roots may partially obstruct the waste, or the earth may be so closely packed at the bottom as to leave no escape for water.

One of the most frequent causes of frozen hydrants is the opening and closing by inexperienced persons, who fail to fully close it, allowing the barrel to remain full of water. Every hydrant used at a fire or for any other purpose should be carefully examined immediately after its use by a competent person who fully understands its working.

The rule allowing no one but fire department employees, and then only at fires, or experienced waterworks employees to open or close any hydrant should be firmly enforced at all times, and even firemen should be fully instructed as to the methods of opening and closing hydrants, especially which way to open and close. Strange as it may seem, there are cities that have hydrants some of which open right and some left.

Stones, [illegible] and even calking hammers, have been found in hydrants after their use, preventing closing. Of course, this is the result of carelessness in laying mains, and the remedy is obvious to all waterworks men.

Pipe [illegible] along a street is a temptation to children and others to fill with stones; we understand from the pipe-[illegible] people that the size and variety of relics they find in mains would [illegible] a museum.

---

*Paper read before American Waterworks Association.

THE DUNMURRY SEWERAGE SCHEME.

By James Hunter.*

The results of the recent census lately published in Great Britain go to prove that the tendency of the wealthier portion of the population of all the large towns is towards migration to the suburbs....... It is chiefly due to this tendency of the population of cities to overflow and enrich the suburban areas near Belfast that caused the construction of a new drainage scheme for Dunmurry.

Dunmurry lies close up to the city of Belfast, and being delightfully situated as a residential area, the building speculators soon became alive to its possibilities in this direction, and in a short time what was formerly a sleepy country village began to develop into a township. Villas were built all round, a new church and new school buildings erected, and later on a factory, with its attendant new laborers' cottages.

The new population, fresh from the city where they had the advantage of the very best sanitary arrangements, were not long contented with the antiquated sanitary arrangements, which had for ages done duty about Dunmurry, and an appeal was made to the council to have Dunmurry put into a proper sanitary condition. After much discussion and many adjournments the council asked me to make a careful inspection of the Dunmurry district, and a report as to what should be done to remedy the grievances complained of. My report was adopted, and I was instructed to prepare a sewerage scheme along the lines indicated in my report, and Mr. Donald Cameron, of Exeter, was appointed consulting engineer. Accordingly, plans, etc., were prepared, passed by the council, and submitted to the Local Government Board, and, after the usual inquiries, were approved by that board.

The tender of Messrs. H. and J. Martin ($44,365), being the lowest, was accepted, and the work was started in November, 1909.

The scheme itself consists of the usual main and branch sewers, with septic tanks, filter-beds, and irrigation area. The main sewer, 12 ft. diameter, begins at the County Bridge, close to Dunmurry Station, and, following the course of the river, extends to the works at Glenburn, a distance of 2,000 lineal yards, crossing the river twice. At the river crossings the main is constructed with cast-iron piping carried on steel girders, the girders resting on concrete abutments, with concrete waterway between.

Where it approaches the works the main is also iron piping carried across a hollow at the river bank on concrete piers, and thence across the river on the parapet of the new approach bridge to works. Most of the main was laid in open cutting, but we had a rather difficult length of tunneling across the main road and under the mill-race, as the bottom for the entire length was through running sand. Indeed, everywhere in the trenches when we got below 9 ft. from surface we came into the same objectionable bottom.

The length of branch sewers is 3,090 yards, and covers all the outlying portions of Dunmurry.

For proper ventilation and cleansing, ventilating columns and Adamez patent flushing syphons have been fixed at the upper end of all branch sewers, while at the lower levels air inlet chambers have been formed at the side of the manholes and opening into same. These chambers are fitted with open covers and have flap valves of thin hammered copper, hung in narrow strips on metal frame, fitted to opening between chamber and manhole. For the cleansing of the main sewer we were able to utilize the river by constructing a concrete chamber with penstock, etc., in the wall at the upper end of main, close to railway station. We found this arrangement very useful and economical during the testing of the works and in the recent dry weather.

The scheme is designed on the separate system, and practically all street surface drainage has been excluded; however, ample provision against congestion has been made by fixing storm overflows at suitable positions along main and large branch sewer.

The Purification Works.—The purification works are situate about one mile from Dunmurry, in a secluded glen lying between the Dunmurry river and the river Lagan, and well away from any possible residential area. The council purchased three acres at this place from the Northern Banking Company, Limited, and that body very generously made a free gift of six acres additional, being the remainder of the field, together with a free bottom for the approach road. The approach is half a mile long, and is carried over the Dunmurry River at two places by bridges of 22-ft. span. Arches of bridges are of Staffordshire blue brick in cement mortar, and the abutments, waterway, wings, and parapets are of concrete. At the bridge close to works concrete training walls have been constructed to prevent erosion in heavy floods.

The Dunmurry River, I may here state, having its source in the hills, is very liable to sudden spates, and rises very rapidly, and is dangerous in flood, as the contractors found to their cost during the progress of the work.

The works consist of four septic tanks, with grit chambers and storm tank, etc., eight filters, and an irrigation area four acres in extent.

The septic tanks are all arched over with the exception of a 6-ft. length at each end, which is covered with planking, on top of which is a thick layer of peat-moss litter. By means of these lengths at each end the tanks are very easily examined and cleaned out. There are also the usual sludge lagoons and an irrigation area for storm water.

The filters are 4 ft. 9 in. deep, and filled 4 ft. deep with washed cinders: top, 12 in., ½ in. to ⅛ in.; bottom, 12 in., 1½ in. to ⅜ in.; and centre portion, ¾ in. to ⅜ in. The filters are worked by automatic gear supplied by the Septic Tank Company, London, and this is at present working satisfactorily.

The irrigation area is laid out level, and is under-drained by agricultural drain pipes laid at an average depth of 1 ft. 9 in. under the surface. These under-drains are joined to a 9-in. main pipe running the entire width of the area and discharging into the Lagan.

The effluent from the filters is distributed over the irrigation area by means of stoneware channels, 9-in. feeders and 6-in. carriers.

At the upper end of the 9-in. main at irrigation area a weir has been constructed in the river so that the main can be cleansed of sediment as often as necessary.

The septic tanks are designed to accommodate a population of 2,500, or double the existing population at the time the scheme was promoted.

The daily water consumption was taken as 25 gallons per head, and allowance has been made for treating three times this quantity, or 180,000 gallons. The dry-weather flow to works during recent dry spell averaged about 30,000 gallons daily.

An analysis of effluent taken on June 23rd last shows that the works, after twelve months' service, are acting well. Two samples were submitted for analysis, one from the gear chamber of effluent from septic tanks, and a second from the outfall pipe at river Lagan of the final effluent. Taking the standard of purity as the oxygen absorbed test, sample

---

* Paper read at the Royal Sanitary Institute Congress at Belfast.

No. 1 gives the amount of oxygen absorbed after four hours at 80 deg. Fahr., as 0.57 per 100,000 parts, and sample No. 2 gives 0.16 parts under similar conditions. The suspended solids the analyst gave as practically nil.

Under a separate contract carried out by the Messrs. Martin, the council have spent a sum of almost £2,000 in connecting up all the houses to the new system....... The district, from being the most insanitary, is now perhaps the most sanitary in the North of Ireland.

In conclusion, I may state that the pipes used in the system were supplied by Messrs. Candy & Co., of Newton Abbot, and have given great satisfaction. The manhole and lamphole covers were manufactured by Messrs. Adams, of York, and the automatic gear by the Septic Tank Company, of London.

◆

STATISTICS OF RAILWAYS IN THE UNITED STATES FOR THE YEAR ENDED JUNE 30, 1911.

The statements in this preliminary abstract are based upon compilations for the Twenty-fourth Annual Statistical Report of the Interstate Commerce Commission, covering the fiscal year ended June 30, 1911, and these advance figures, which do not cover switching and terminal companies, may be slightly affected by revision before final publication.

Mileage.—Substantially complete returns were rendered to the commission for 246,124.40 miles of line operated, including 11,006.86 miles used under trackage rights. The aggregate mileage of railway tracks of all kinds covered by operating returns was 362,710.18 miles. This mileage was thus classified: Single track, 246,124.40 miles; second track, 23,451.26; third track, 2,414.16; fourth, fifth, and sixth tracks, 1,747.10; yard track and sidings, 88,973.26. These figures indicate an increase of 10,943.59 miles over corresponding returns for 1910 in the aggregate length of all tracks, of which increase 3,391.33 miles, or 30.99 per cent., represent yard track and sidings.

Equipment.—It appears that there were 61,327 locomotives in the service of the carriers on June 30, 1911, indicating an increase of 2,380 over corresponding returns for the previous year. Of the total number of locomotives, 14,301 were classified as passenger, 36,405 as freight, and 9,324 as switching, and 1,297 were unclassified.

The total number of cars of all classes was 2,359,335, or 69,004 more than on June 30, 1910. This equipment was thus assigned: Passenger service, 49,818 cars; freight service, 2,195,511; and company's service, 114,006. The figures given do not include so-called private cars of commercial firms or corporations.

It appears that the average number of locomotives per [illegible] miles of line was [illegible], and the average number of cars per 1,000 miles of line was 9,586. The number of passenger-miles per passenger locomotive was [illegible], and the number of ton-miles per freight locomotive was 6,913,246.

The returns indicate that the number of locomotives and cars in the service of the carriers aggregated [illegible], of which [illegible] per cent. [illegible] were fitted with train brakes, and [illegible] per cent. [illegible] were fitted with automatic couplers. Of the 2,195,511 cars in freight service on June 30, 1911, the number fitted with train brakes was [illegible], and the number fitted with automatic couplers was [illegible].

Employees.—The total number of persons reported as on the pay rolls of the steam roads of the United States on June 30, 1911, was 1,669,809, or an average of 678 per 100 miles of line. As compared with returns for June 30, 1910, there was a decrease of 29,611 in the total number of railway employees. There were 63,390 enginemen, 66,376 firemen, 48,200 conductors, 133,221 other trainmen, and 40,005 switch tenders, crossing tenders, and watchmen.

The total number of railway employees (omitting 93,718 not distributed) was apportioned among the six general divisions of employment as follows: To maintenance of way and structures, 493,926; to maintenance of equipment, 344,112; to traffic expenses, 22,246; to transportation expenses, 629,654, to general expenses, 52,201; and to outside operations, 33,952.

The complete report will include summaries showing the the average daily compensation of 18 classes of employees for a series of years, and also the aggregate amount of compensation reported for each of the several classes. The total amount of wages and salaries reported as paid to railway employees during the year ended June 30, 1911, was $1,208,466,470.

Capitalization of Railway Property.—On June 30, 1911, the par value of the amount of railway capital outstanding, according to the returns of the companies filing reports with the commission, was $19,208,935,081. This amount includes capital held by the railway companies as well as by the public.

Of the total capital outstanding, there existed as stock $8,470,717,611, of which $7,074,917,559 was common and $1,395,800,052 was preferred; the remaining part, $10,738,217,470, representing funded debt, consisted of mortgage bonds, $7,825,269,102; collateral trust bonds, $1,183,766,188; plain bonds, debentures, and notes, $951,377,816; income bonds, $261,777,220; miscellaneous funded obligations, $195,430,395; and equipment trust obligations, $319,596,749.

Of the total capital stock outstanding, $2,740,467,285, or 32.35 per cent., paid no dividends. The amount of dividends declared during the year (by both operating and lessor companies) was $460,195,376, being equivalent to 8.03 per cent. on dividend-paying stock. No interest was paid on $755,449,047, or 7.25 per cent. of the total amount of funded debt (other than equipment trust obligations) outstanding.

Public Service of Railways.—The number of passengers carried during the year ended June 30, 1911, was 997,409,882. The corresponding number for the year ended June 30, 1910, was 971,683,199. The increase in the number of passengers carried during the year over 1910 was 25,726,683.

The number of passengers carried 1 mile, or the passenger mileage, as compiled for 1911, was 33,201,694,699. The corresponding return for 1910 was 863,198,370 less. The number of passengers carried 1 mile per mile of road was 139,101.

The number of tons of freight shown as carried (including freight received from connections) for the year ended June 30, 1911, was 1,781,637,954, while the corresponding figure for the previous year was 1,849,900,101, the decrease being 68,262,147 tons.

The ton mileage, or the number of tons carried 1 mile, as shown for the year ended June 30, 1911, was 253,78[illegible]. The total ton mileage as reported for the year ended June 30, 1910, was 255,016,910,451, from which it will be seen that the decrease in the ton mileage for the year ended June 30, 1911, under the return for 1910 was 1,233,208,612. The increase in the number of tons carried 1 mile in 1910 over 1909 was [illegible]. The number of tons carried 1 mile per mile of road for the year 1911 was [illegible]. The number of tons per train mile was 383.10.

The average receipts per passenger per mile, as computed for the year ended June 30, 1911, were 1.974 cents; the average receipts per ton per mile, 0.757 cent. The passenger service train revenue per train-mile was $1.30.921; the freight revenue per train-mile was $2.89.548. The average operating revenues per train-mile were $2.24.824. The average operating expenses per train-mile were $1.54.338. The ratio of operating expenses to operating revenues was 68.66 per cent.

Revenues and Expenses.—It should be noted that the following figures under the heading of revenues and expenses exclude returns for a few small roads because of deficiencies in their reports. For the year ended June 30, 1911, the operating revenues of the railways in the United States (average mileage operated, 243,433.61 miles) were $2,789,761,669; their operating expenses were $1,915,054,005. The corresponding returns for 1910 (average mileage operated 236,986.51 miles) were: Operating revenues, $2,750,667,435; operating expenses, $1,822,630,433. The following figures present a statement of the operating revenues for 1911 in detail:—

Freight revenue	$1,925,950,887
Passenger revenue	657,638,291
Mail revenue	50,702,625
Express revenue	70,725,137
Excess baggage revenue and milk revenue (on passenger trains)	15,430,683
Parlor and chair car revenue and other passenger-train revenue	5,274,450
Switching revenue	27,665,997
Special service train revenue and miscellaneous transportation revenue	9,479,809
Total revenue from operations other than transportation	24,707,757
Joint facilities revenue—Dr.	647,247
Joint facilities revenue—Cr.	2,833,280
Total operating revenues	$2,789,761,669

The operating revenues stated above averaged $11,460 per mile of line.

Operating expenses, as assigned to the five general classes, were:—

Maintenance of way and structures	$ 366,025,262
Maintenance of equipment	428,367,306
Traffic expenses	59,166,364
Transportation expenses	987,382,108
General expenses	73,689,373
Unclassified	423,592
Total operating expenses	$1,915,054,005

The foregoing operating expenses averaged $7,867 per mile of line.

MAGAZINES AND THAW HOUSES FOR EXPLOSIVES.

"Magazines and Thaw Houses for Explosives" is the title of Technical Paper No. 18 just issued by the United States Bureau of Mines. The authors, Clarence Hall and S. P. Howell, present the advanced practice abroad and in the United States on the use of material for the construction of magazines and thaw houses and strongly recommend the use of a lean cement mortar consisting of 6 parts of sand and 1 part of cement as the material to be used in the walls, roof, and doors of these buildings in order that the explosives within them may be properly protected, also in order that life and adjacent property may not be jeopardized when magazines and thaw houses are constructed the proper distances from other buildings.

In order that the explosives in magazines may be properly protected they must be guarded against bullets, fire, lightning, and unlawful entry. Different fireproof materials were experimented with to determine their resistance to the penetration of rifle bullets. Sand offered some advantages, but was rejected because it would eventually flow out on the floor of the magazine through the cracks in the walls and could not be depended upon to remain in the structure permanently; moreover, gritty materials of any kind are objectionable on the floor of a magazine. Mineral wool overcame this objection but had little value as a medium for resisting the penetration of rifle bullets. Therefore, in order to overcome the objectionable features of sand, Portland cement was mixed with it in order to form a lean cement mortar and thus enable the sand to be retained within the walls of the magazine, and still be friable enough to crumble readily under a blow. Tests to determine these two features were so satisfactory that a magazine having this cement mortar as a filling was constructed by the Bureau of Mines at a cost of $400 and having a capacity of 20,000 to 30,000 pounds. A working drawing showing the dimensions and necessary sections are included in the publication. The means provided for ventilation in the magazine of the Bureau of Mines has been found to be adequate and, accordingly, the storage of explosives in respect to their keeping qualities is favorable.

The cement mortar construction is effective in resisting the penetration of rifle bullets and owing to its friable nature offers an additional advantage for the reason that, in the event of an explosion in or near the magazine, the large masses of material would not be projected over the surrounding country. The galvanized iron covering is fire-resisting and at the same time it serves as an excellent medium for protection against lightning when the four corners of the building are properly grounded with metal rods.

The method of selecting a magazine site is emphasized and suggestions made. The permissible distance which must obtain between magazines and other structures in England, Prussia, Austria, Italy, Massachusetts, and also the proposed American table of distances are contained therein.

The proper method of thawing explosives in either small or large quantities and a suitable method of transporting them to the place where they are to be used is described in this Technical Paper.

A temperature not exceeding 90 deg. Fahr. is recommended in thawing explosives. In all cases explosives must be protected against moisture and high temperatures and for this reason thawing explosives by placing them before a fire or near a boiler or on steam pipes or by putting them in hot water is condemned.

Copies of this Technical Paper may be obtained by writing to the director of the Bureau of Mines, Washington, D.C.

TELEGRAPH LINES DAMAGED BY DYNAMITE EXPLOSION.

While attempting to loosen dirt for the steam shovel, used in the excavation of the Canadian Pacific Railway station extension in Vancouver, by a charge of dynamite the telephone and telegraph lines of the system were badly damaged. Two poles were cut in two and a third driven into the ground at an angle.

COMPARATIVE STRENGTH AND RESISTANCE OF VARIOUS TIE TIMBERS.

The following series of tests were conducted in the physical laboratory of the Armour Institute of Technology, under the supervision of engineers representing the track department of the Board of Supervising Engineers, Chicago Traction, and were published in the third annual report of the board recently issued. The purpose of the tests was to determine the comparative strength and resistance of various tie timbers used in the construction of street railway track under the board's supervision.

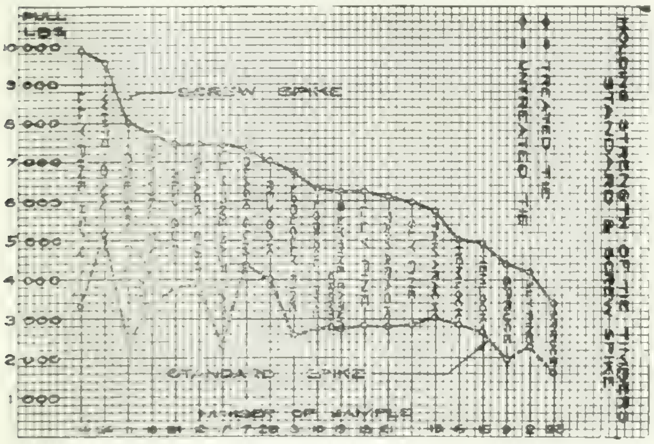

Fig. 1.
Comparative Holding Power of Standard Screw Spikes in Various Timbers.

Spike-pulling Tests.—The special object of these tests was to determine the comparative holding power of the standard track spike and of the screw spike developed by the Board in various timbers. Three spikes of each kind [illegible] samples were used [illegible] [illegible] in the same depth [illegible] [illegible] track construction. These spikes were then withdrawn at right angles to the face of the tie by [illegible] at a speed of [illegible] per minute. The [illegible] [illegible] [illegible]

The [illegible] the screw spike [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible]

Indentation Tests.—Tie plates were placed on a tie as in track construction. A steel casing with a face equal to that of the base of the standard rail (6 ins.) was mounted on the plate and then loads were applied at right angles to the tie plate, directly from the compression head of the testing machine, at a speed of 1/16 in. per minute, and an initial load of 500 lbs. was used in all tests, to which load frequent returns were made from the higher loads. All indentations were measured by a deflectometer reading to 1/1,000 in., fastened under the compression head of the testing machine.

The materials used in the test timbers were as follows: Short leaf yellow pine (untreated); loblolly pine, treated with chloride of zinc; short leaf yellow pine, early growth, treated with chloride of zinc; long leaf yellow pine, half sap, treated with chloride of zinc; long leaf yellow pine (untreated); black gum, treated with chloride of zinc; white oak (untreated); hemlock (untreated); spruce (untreated); long leaf yellow pine heart (untreated); red gum (untreated); red oak (untreated). All of these ties were well seasoned and dry. The screw spike was of the Board of Supervising Engineers' standard, and the track spike was of the standard railway type, 5½ ins. by 9/16 in. The tie plates tested were of the Board of Supervising Engineers' standard, one with a flat bottom, 6 ins. by 9½ ins., and the other having a corrugated bottom of the same size.

Results of Tests.—The results of the tests as presented in the accompanying tables and curves may be summarized as follows:—

(1) Although the holding power of the screw spike is approximately three times that of the standard 5½-in. by 9½-in. track spike in any given timber, the relative holding power in the different timbers is such as to make the screw spike in treated pine timbers fully equivalent to the standard track spike in good white oak.

(2) In reference to the resistance of the fibre of the wood to the indentation of a tie plate, the ratio of this resistance for a flat bottom plate to that for a corrugated bottom plate is decidedly greater than the ratio of the bearing area of the flat bottom plate to that of the corrugated bottom plate. In other words, for the same unit load per square inch of actual surface contact, the indentation with the corrugated plate is considerably greater than with the flat bottom plate.

(3) The chloride of zinc treatment used for preservative purposes on the loblolly and short leaf yellow pine ties has the additional feature of increasing the fibre strength of these timbers to such an extent as to make

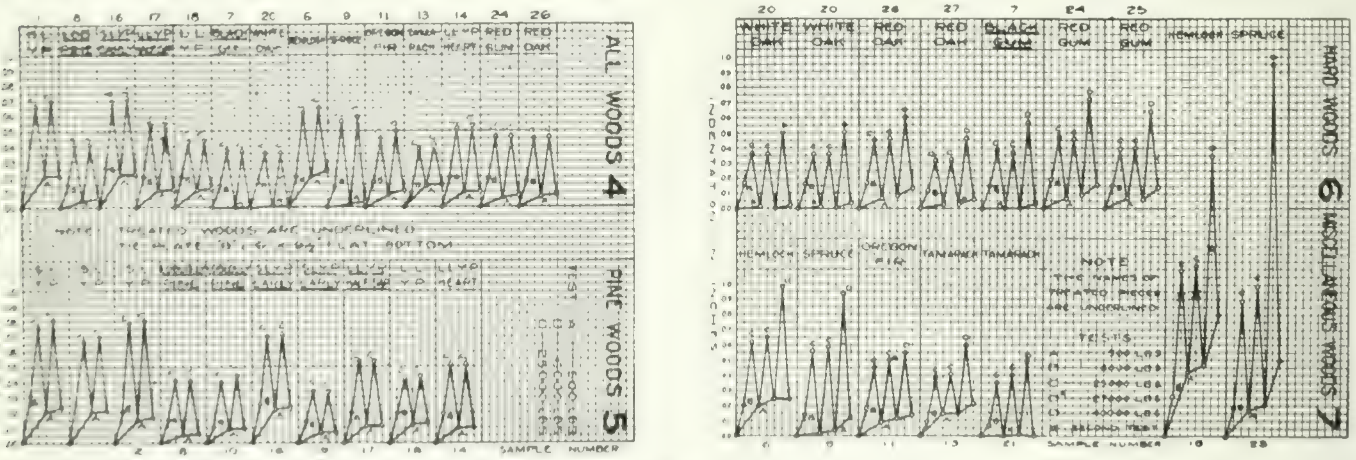

Fig. 2.
(4, 5) Comparative Deformation of Tie Timbers with Flat Tie Plate, for All Woods and for Pine Only.
(6, 7) Comparative Deformation of Hard Woods and Various Woods—Flat Tie Plates.

them compare favorably with the long leaf yellow pine ties in resisting indentation of a tie plate.

(4) The adoption of a flat tie plate with its increased bearing area as a remedy for track deflection, due to permanent deformation of the timber fibres, was fully warranted by the results of this investigation.

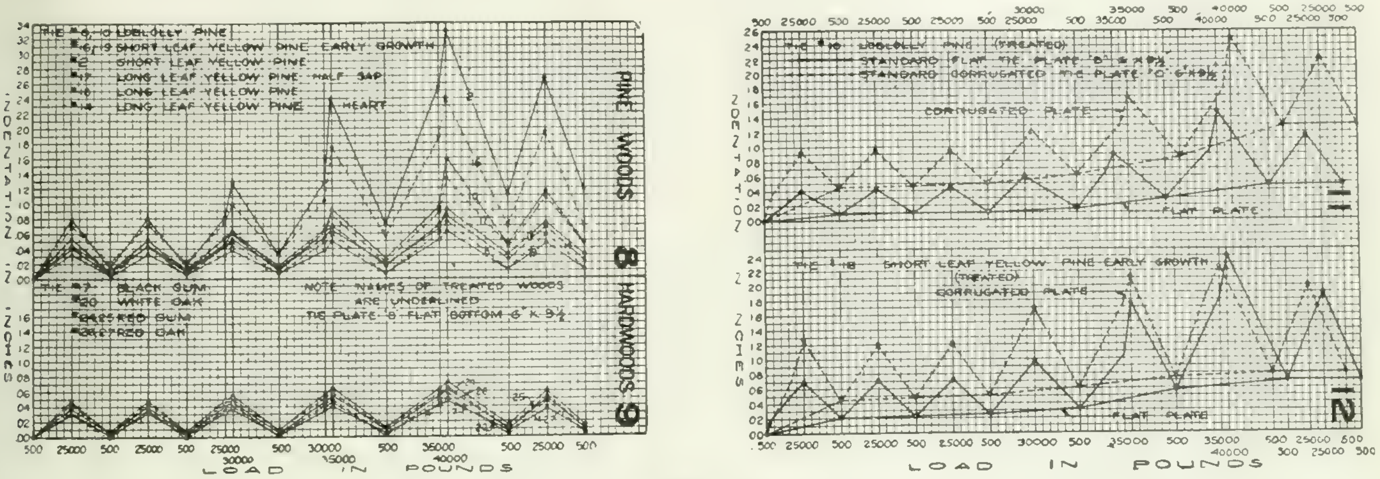

Fig. 2.

(8, 9) Comparative Deformation of Pine Ties and Hard Wood Ties Under Successive Load—Flat Tie Plates.
(11, 12) Comparative Deformation of Loblolly and Short Leaf Yellow Pines, with Flat and Corrugated Tie Plates.

Comparing the results of these spike-pulling tests with those previously recorded by the board, it is of interest that in all cases the preliminary data relating to the holding power of screw spikes were independently confirmed by the results of the 1909 tests, and were shown to be very conservative.

Holding Power.—Fig. 1 compares the relative holding power of standard and screw spikes in various timbers, these timbers being ranked according to the relative holding strength with the screw spike. The lower curve indicates the relatively less holding power of the standard spike observed in all cases. With few exceptions, this relative proportion holds throughout the test. It is apparent from the curves that the softer woods have not over one-half the strength of the harder woods, or of long leaf yellow pine, mostly heart.

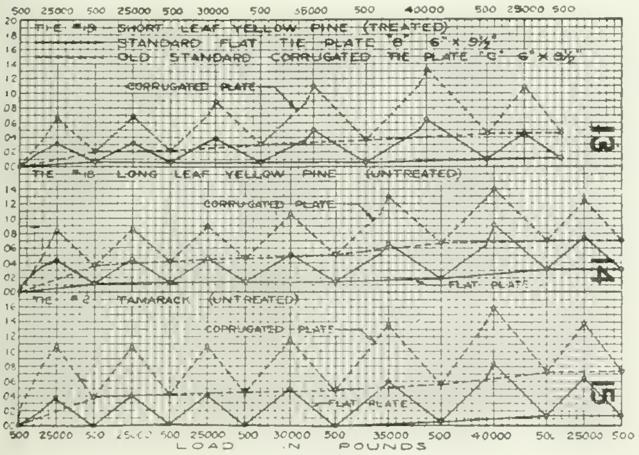

Fig. 2.

(13, 14, 15) Comparative Deformation of Short Leaf and Long Leaf Yellow Pines—Flat and Corrugated Tie Plates

Indentation.—The indentation tests, Figs. 2 (4, 5), are represented in the two forms; plates 4, 5, 6 and 7 summarize the results on typical timber samples with two or three applications of maximum pressure; plates 8 and 9 may be regarded as the deterioration tests indicating the permanent deformation of fibre and cumulative injury under excessive maximum loads; plates 11 and 15 represent typical deterioration tests, on various timber, showing, in addition, the fatigue curve resulting from the use of the corrugated tie plate as compared with the flat tie plate. The so-called fatigue manifests itself in the fact that with successive applications of the same pressure, the fibres did not show complete recovery. Gradual assent of the fatigue curve, therefore, indicates permanent deformation of the wood fibres, and in all cases, that of a corrugated tie plate is considerably greater than the flat plate, owing to the smaller bearing area.

During none of these indentation tests was the load entirely removed, as the resulting possible change in tie plate contact might have entirely vitiated the results indicating abnormal recovery at minimum load; consequently, the load was not reduced below 500 lbs. Plate 4 shows clearly recovery from load C to load A in succession, thus with short leaf yellow pine, untreated, permanent deformation resulted only from the first application of 25,000 lbs. load, but the second application showed practically no further deformation. Hemlock, untreated, on the other hand, showed continued deformation, while white oak showed practically complete recovery with no deformation. In these tests, load B represents approximately the tie plate load, such as would result from the passing of an ordinary car. In plate 7, some of the softer woods were tested to practical failure. Tests on hard woods (plate 9) are remarkable in the coincident of the results and the complete recovery.

Deterioration of Screw Spikes.—Examination of track built in previous years showed that where screw spikes have been inserted in ties treated with zinc chloride, a deterioration of the spike resulted. The reason for the damage is believed to be local, chemical and galvanic action in the bored spike hole, which usually contains water, each spike hole forming a single cell containing a strong solution of zinc chloride in which the screw spike is immersed. Free chlorine and hydrochloric acid gases assist in the destruction. While there seems to be no immediate remedy at hand which might be applied to stop or partially suspend the deterioration which is going on apparently at all times, the obviation of this difficulty in the future will be obtained by abandonment of zinc treated ties for ties treated with creosote.

MANUFACTURERS' STANDARD FOR FLANGED FITTINGS AND FLANGES, STANDARD AND EXTRA HEAVY PRESSURES, ADOPTED JULY 10, 1912, EFFECTIVE OCTOBER 1, 1912.

By W. H. Douglas, Secretary Committee of Manufacturers on Standardization of Fittings and Valves.

The standard recently adopted jointly by the Master Steam and Hot Water Fitters' Association and the American Society of Mechanical Engineers, and known as the "1912 U.S. Standard," is the outgrowth of an effort on the part of these two societies to establish a universal standard for flanged fittings and flanges for working steam pressures in ordinary use at the present time.

Without question, a universal standard is necessary and highly desirable; but any standard to be commercially successful must be designed to bring about the desired uniformity with the minimum inconvenience and expense, both to consumers and to manufacturers.

Before the "1912 U.S. Standard" was adopted by the two societies mentioned, there existed among the majority of manufacturers, in the United States, a generally accepted standard for flanged fittings and flanges. Most of the large flanged fittings manufacturers in this country had the entire pattern equipment necessary to build this line of goods and many had list prices and dimensions published for general distribution to the trade; in fact, these dimensions have been published in Kent's Pocket Book, 8th Edition.

After having thoroughly investigated the conditions which induced the two societies to adopt the "1912 U.S. Standard," the manufacturers of flanged fittings and flanges throughout the country realized that certain changes in the generally accepted standard were desirable. The tendency of modern engineers to use higher steam working pressures than was their practice some years ago has demonstrated the necessity for an increase in the strength of extra heavy end flange bolting in the larger sizes. In drafting up the "1912 U.S. Standard," the American Society of Mechanical Engineers provided an increase in the bolting of large extra heavy flanges; but this increase seems out of proportion [illegible] steam engineering practice. The manufacturers have, therefore, adopted a happy medium and have increased the bolting on these extra heavy flanges, but have been more practical in this increase than the "1912 U.S. Standard."

So far as the strength of the "Manufacturers' Standard," not considering the bolting, is concerned, the "1912 U.S. Standard" has no advantage whatever over the manufacturers' standard.

While the "1912 U.S. Standard" provides longer centre [illegible]

[illegible]

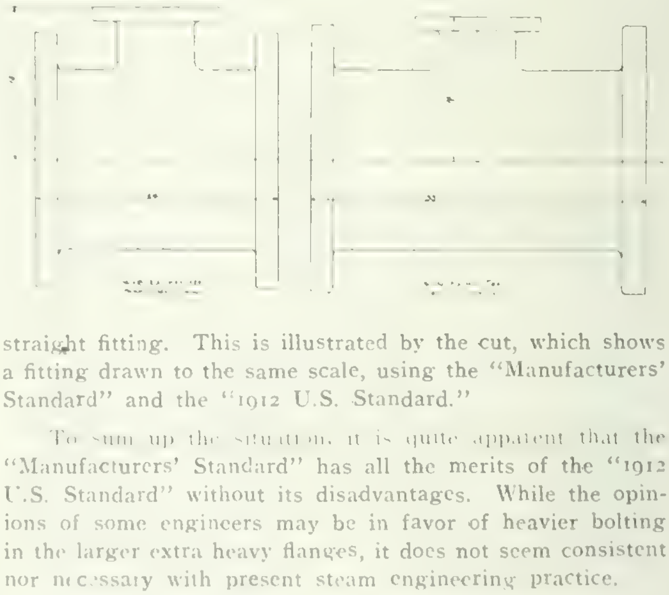
[illegible]

While the "1912 U.S. Standard" provides much heavier bolting on the very large extra heavy flanges, this excessive increase does not seem necessary, as the "Manufacturers' Standard" bolting is just as strong as the "1912 U.S. Standard" on the sizes which include the great majority of pipe lines; namely, the ten-inch size and smaller.

The "Manufacturers' Standard" is much more economical for the consumer of the future, in avoiding mistakes when making changes and additions to his plant, as no change is made in the centre to face dimensions from the present "Manufacturers' Standard." This standard is also economical for the manufacturer, as he can use his present equipment, which, to a large extent, is made up in very substantial fashion and cannot be changed without involving a very high expenditure.

Furthermore, the "1912 U.S. Standard" will naturally create a great deal of confusion to the consumer, jobber and manufacturer alike, as it would necessitate carrying two stocks of fittings for several years, or until the new standard is fully in effect. The "Manufacturers' Standard" will not cause this difficulty.

The "Manufacturers' Standard" for reducing fittings is a much better design than the "1912 U.S. Standard," as the fittings are more in proportion with the straight sizes. The "1912 U.S. Standard" has the same dimensions on the run of reducing fittings as the straight sizes, regardless of reduction. It will be readily seen that the proportions of a reducing fitting will not be in harmony with those of a straight fitting. This is illustrated by the cut, which shows a fitting drawn to the same scale, using the "Manufacturers' Standard" and the "1912 U.S. Standard."



To sum up the situation, it is quite apparent that the "Manufacturers' Standard" has all the merits of the "1912 U.S. Standard" without its disadvantages. While the opinions of some engineers may be in favor of heavier bolting in the larger extra heavy flanges, it does not seem consistent nor necessary with present steam engineering practice.

It would seem apparent that the excessively large bolt diameters specified in the "1912 U.S. Standard" for the larger flanges are much too cumbersome and inconvenient from the steam fitters' standpoint, while the bolt sizes specified in the "Manufacturers' Standard" are more in accordance with general practice. In a standard of this nature convenience as well as strength should be a governing factor.

We feel confident that the public at large will express their preference for the "Manufacturers' Standard," and while the manufacturers may be accused of not taking an interest in the "1912 U.S. Standard" from its inception, their recent action in adopting a universal standard which is fully in accord with the requirements of the engineering trade, will demonstrate that they are acting with absolute sincerity and with a fair-minded attitude towards all interests involved.

COAL-DUST EXPLOSIONS.

The first report of the Explosions in Mines Committee, of which a summary appeared in the London Times recently, confirms some of the opinions which have already been expressed regarding the deterrent influence of stone-dust upon explosions, and it is satisfactory to observe that the committee are making progress with an investigation which must of necessity be developed by a step-by-step process upon the basis of direct experiment. From the programme of their prospective researches it appears that they have to examine the nature and condition of the coal-dust in mines, the amount and purity of the oxygen supply, and the character of the initial conditions that result in ignition. They have, moreover, to determine the comparative violence of coal-dust explosions, and the modifications of the destructive forces depending upon the general dimensions and layout of the mines. It is an investigation in which theory is singularly impotent to give direction to the research. Theory, in fact, must play the secondary part of interpreting results and suggesting certain safeguards, and the reason is that the committee are dealing with a set of phenomena that concern the break-up of the substance in a fraction of time altogether too small for the calculation by ordinary means of a series of constants representative of the successive stages of the explosions. Their investigation is, in fact, as far removed as can be imagined from the ideal conditions and the "perfect gas" relationships of thermodynamics. Since 1824, when Sadi Carnot published his remarkable contribution to the problem of the expansion of gases, the internal combustion engine has forced engineers to extend their tests far beyond the conditions of stability which he assumed into the region of explosion and disassociation; nevertheless, there is still a disposition to assume relationships between temperature, volume, and pressure applicable only to the gas in Carnot's engine, which was always brought back to its original condition. Briefly, therefore, the complexity of the task before the committee arises from the circumstance that they have to take account of the intrinsic energy of the working substance, which the laboratories have too often eliminated. The experimental station which has just been established at Eskmeals is destined to play an important part in that investigation, and every engineer will hope that it will rapidly reveal the means of safeguarding the lives of miners and of improving the physical conditions under which they work.

◆

CANADA'S FIRE LOSSES

The fire losses in Canada for the first six months of the current year total $14,740,499, an average of $2,456,750 per month. This is equal to a daily loss of $81,891. In other words, $3,412 worth of property has been burned every hour since the new year dawned, or nearly $57 every minute.

This is an appalling fire loss, and little is being done to check such extravagant waste of capital. The losses during 1909, 1910 and 1911 are as follow:—

	1909.	1910.	1911.
January	$1,500,000	$1,275,246	$2,250,550
February	1,203,005	750,025	941,045
March	851,000	1,070,253	852,380
April	720,050	1,717,237	1,317,000
May	3,358,276	2,735,536	2,564,500
June	1,300,275	1,500,000	1,151,150

	1909.	1910.	1911.
July	1,075,600	6,386,674	5,384,300
August	2,582,915	1,667,270	920,000
September	1,615,405	894,125	1,123,550
October	2,208,718	2,195,781	580,750
November	935,191	1,943,708	1,506,500
December	1,433,813	1,444,860	2,866,950
Total	$18,905,538	$23,593,315	$21,459,575

Adding to these figures the total loss for the first six months of 1912, we have a fire loss in forty-two months of $78,698,927, an average monthly loss of $1,873,785. In addition there has to be recorded a disastrous list of fire fatalities. During June in Canada six people met their deaths in fires. During the first six months of the year 101 people were sacrificed in the same manner. In the forty-two months since January, 1909, no less than 893 persons lost their lives in fires, a monthly average of almost 22 persons. The following table gives the details:—

	1909.	1910.	1911.	1912.
January	16	27	27	27
February	8	15	12	11
March	16	20	18	24
April	18	37	20	15
May	21	15	28	18
June	16	52	13	6
July	4	15	110	..
August	17	11	22	..
September	10	10	13	..
October	26	16	17	..
November	34	19	20	..
December	33	19	17	..
Total	219	256	317	101

In June, burning buildings were responsible for three deaths and three were caused by clothes set on fire.

The presumed causes for fires during June and the number of fires for which they accounted were as follows: Four, lamp explosions; three, children playing with matches; two each, cigarette stubs, incendiary, sparks, friction; one each, oil stove explosion, defective chimney, overflowing of a pot of soap grease. Forest fires did much damage and many fires were reported as of unknown origin.

The structures damaged and destroyed during June were 70 residences, 9 business sections, 5 stores, 4 each lumber mills, factories, 3 foundries, 3 each stables, barns, 2 each churches, hotels, freight sheds, 1 each rolling mill, flour mill, railway depot, roundhouse, power house, club house, ice-house, telephone exchange, pool room, barber shop, college, soda water works, grain warehouse, gasoline container, electric plant.

There were 500,000 staves, 15 tons hay, 6 horses, 2 miles wire fencing, 1 each buggy, motor launch, gasoline truck destroyed.

The National Board of Fire Underwriters of the United States, continuing its plan of education on the need of better protection, issued an exhaustive classification of fire losses recently, showing why the insurance companies are forced to ask higher rates in America than in Europe, and why rates in America itself necessarily vary. Taking thirty of the largest cities of the United States, the per capita loss in 1909 was shown to vary from $1.[illegible] in St. Louis to $4.55 in Kansas City. Higher per capita loss was shown in some of the smaller centres, like the city of Racine, where it ran to $24.29. The total annual fire loss is estimated at $200,000,000, and the underwriters go so far as to assert that $150,000,000 of this is waste from negligence or lack of precautions. The table of comparisons drawn up by the underwriters from consular returns in 1905, the only recent year in which statistics of the kind were gathered in Europe, showed an average loss of 61 cents per capita for thirty European cities as against $3.10 for 252 American cities Taking the number of fires to each 1,000 of population here and in Europe, it was found to be 4.05 in the United States against .86 in Europe.

The annual average losses for six nations in Europe were compiled from records of varying years and years grouped, with this result:—

Country.	Annual fire loss.	Loss per capita. Cents.
Austria	$ 7,601,389	29
Denmark	660,924	26
France	11,699,275	30
Germany	27,655,600	49
Italy	4,112,725	12
Switzerland	999,364	30

Or an average loss per capita of 33 cents.

The fire loss per capita in the Dominion last year was $3.02.

On Berlin, where the losses amount annually to less than those of one moderately large fire in the United States, the excellent conditions are due to the attention paid to the methods of construction. Building police have authority to compel the use of iron and steel girders, fireproof stairways and roofing, heavy fireproof ceilings, and all details that may diminish the risk of conflagration.

Canada cannot claim to be making untrammeled progress until its fire record has been improved considerably.

◆

LETTERS TO THE EDITOR.

Editor Canadian Engineer:

Dear Sir,—In your issue of June 27th, 1912, you published an article by Mr. F. M. Griswold on "Standard Hose Couplings and Hydrant Fittings," being a review of the progress made in introducing a standard in the United States; strange to say, little or nothing has yet been done in Canada in regard to this important matter.

Some time ago the question was taken up by the Western Canada Fire Underwriters' Association, whose jurisdiction extends over the Provinces of Manitoba Saskatchewan and Alberta. It was our intention at first to attempt to introduce the "National Standard," but the suggestion met with opposition from fire chiefs. Our next step was to find out what couplings are used in the towns and cities throughout this territory, and we found that two towns use five threads per inch; seventeen use six threads per inch; four, including two very small places, use seven threads per inch, and three use eight threads per inch. The list includes all the cities and towns which have waterworks systems in this territory, with the exception of four or five small places. We found that fire chiefs are almost unanimously in favor of the six-thread coupling, as it will stand more wear than the finer thread and is not so easily crossed; it is also a heavier coupling, being 3 3-16 inches outside diameter over the male end. After some discussion we came to the conclusion that, as the six thread coupling is so largely used, it would be very difficult, if not impossible, to have a change made to something else, and we decided it would be best to follow the line of least resistance and make this coupling a standard throughout our territory. As these three provinces extend from the rocky country of Western Ontario on the east to the Rocky Mountains on the west, it is improbable that there will ever be any large cities close to us on either side, and to have a uniform thread all through this territory will be almost as good as a standard for the whole country. One non-standard town in Saskatchewan has practically agreed to change, after which all the towns in that province will be standard.

If you will kindly publish this letter, it will be the means of bringing the matter to the attention of engineers who may be engaged in the installation of water supply systems in this part of the country.

H. STAINTON,
Inspector W.C.F.U.A.

* * * *

THE BLOOR STREET VIADUCT.

Sir,—It is with the greatest degree of satisfaction that I have noted the editorial in your number of the 8th instant protesting against the official statement of the Commissioner of Works of the city of Toronto in a report to the Board of Control that "concrete bridge design is not well understood, while that of steel is upon an assured basis."

The statement is made, apparently, with reference to the type of construction to be adopted for the proposed Bloor Street viaduct in Toronto, but its connection therewith is quite secondary in importance to the statement itself. That such a statement should be officially made by the chief works officer of the second city of our fair Dominion is amazing, and in the interest of truth and in justice to our profession you do well to take issue with the person who made it.

The commissioner must know, if he has studied the subject at all, that the greatest stride made by the engineering and architectural professions in structural design since the development of the great orders of architecture is in reinforced concrete construction. Its adaptability to structures of all kinds is proven beyond all doubt as regards both strength and design. Its permanence equals that of the everlasting hills.

The success or failure of isolated examples of any type of structure as a result of errors in workmanship or design proves nothing. One type is no better than another if errors have crept in anywhere. For the information of the commissioner I would join with you and emphasize your statement that "the analysis of stresses and the knowledge of the action of concrete is to-day on as high a plane as any other branch of structural design."

For myself, I cannot think that the commissioner has had any engineering training, and I feel quite certain Mr. Power never made such a statement as that which is contained in the report to the Board. To let such a statement go unnoticed would reflect discredit on the excellent work already done by the civic staff of Toronto, and on the work done by Canadian engineers throughout this broad Dominion. It would hold us up to ridicule before the Dominion, and the profession to ridicule before the world.

Such questions as that with which the report deals cannot be answered lightly. I know of no engineer who would decide such a question for the reasons given in the report. There exists no engineer who would make the statement so manifestly one-sided and at variance with the facts as "concrete bridge design is not well understood, while that of steel is on an assured basis."

WALTER J. FRANCIS,
M.Can.Soc.C.E. M.Am.Soc.C.E.
Montreal, August 12, 1912.

GENERAL NOTES.

The distribution of precipitation during July varied considerably with the district, but speaking generally, the amount recorded from British Columbia, to and including Manitoba, also Eastern Quebec, and the Maritime Provinces was considerably above the average, while in other districts the fall was deficient. Locally in the Lower Mainland of British Columbia, Southeastern Alberta, Southwestern Saskatchewan, and Southwestern Nova Scotia, the registered value was subnormal, while in parts of the Peninsula and Central Districts of Ontario, the fall exceeded the normal. In many parts of the Western Provinces the precipitation was nearly double the normal and heavy thunderstorms were of frequent occurrence.

The table shows for fifteen stations, included in the report of the Meteorological Office, Toronto, the total precipitation of these stations for July, 1912:

	Depth in inches.	Departure from the average of twenty years.
Calgary, Alta.	5.2	+2.6
Edmonton, Alta.	4.7	+0.95
Swift Current, Sask.	2.3	—0.21
Winnipeg, Man.	6.1	+2.77
Port Stanley, Ont.	4.0	+0.64
Toronto, Ont.	1.95	—0.98
Parry Sound, Ont.	1.4	—1.73
Ottawa, Ont.	4.9	+0.80
Kingston, Ont.	1.6	—1.26
Montreal, Que.	2.3	—1.66
Quebec, Que.	2.0	—2.43
Chatham, N.B.	6.5	—2.78
Halifax, N.S.	4.7	+1.14
Victoria, B.C.	1.1	+0.85
Kamloops, B.C.	3.5	+2.24

The value of the material used in the slack cooperage industry in Canada in 1911, according to figures prepared by the Forestry Branch, Department of the Interior, was $1,465,702, or about $130,000 less than the value in 1910. The amount of material consumed, outside of a large element of waste, which cannot be accurately determined, is estimated at 62,353,190 feet, board measure.

Ontario leads in this industry, with the production of 64 per cent. of the total number of staves, 70 per cent. of the headings and 76 per cent. of the hoops. Nova Scotia, with a large proportion of fish-barrels, was next with 29 per cent., 24 per cent. and 20 per cent, respectively, of the total number of staves, heading and hoops. The other provinces produce very limited quantities.

Imports exceeded exports of $135,463 by $194,529. White oak staves form an important part of the imports, numbering, in all, 7,293,000, whereas only 2,768,000 were cut in Canada. The Canadian supply of oak, which alone is suitable for the manufacture of containers for alcoholic beverages, is so nearly exhausted that this branch of the tight cooperage industry will practically cease in a few years.

The cost of materials for slack cooperage averaged as follows per thousand pieces: Staves, $6.91; heading, (sets) $54.77; hoops, $7.62. Figures on the cost of tight cooperage materials were not available.

NEW FLOATING DOCK FOR MONTREAL.

An interesting event, during the presence of the Canadian Ministers in London, England, was a visit paid by some of them to the English Lake District, for the purpose of inspecting and naming the "Duke of Connaught," which is the large floating dock that has just been completed by Messrs. Vickers, Ltd., Barrow-in-Furness, for service at Montreal.

The party left by special train on Saturday afternoon, the 20th July, for Furness Abbey, which is situated a few miles from Barrow. The event took place on Monday morning, when the visitors were driven to the new dock, which was then inspected, and the naming ceremony successfully completed by Mrs. J. D. Hazen, wife of the Minister of Marine.

The new dock, which has been named after the Governor-General, with his permission, has been constructed for the firm of Canadian Vickers, Ltd., which is establishing at Montreal, large works for the construction and repair of battleships up to such large vessels as the [illegible] type and also for other sea-going ships.

It is generally considered in England that this is a great step in connection with the naval policy of Canada, and that it will mean a great deal, not only to the citizens of Montreal but also to the Dominion as a whole. It was pointed out that [illegible] Halifax before repairs [illegible] could be undertaken. This condition would be [illegible] by the presence of a floating dock in the St. Lawrence. The advantage of a floating dock [illegible] it may be towed to any point on the Atlantic seaboard of the Dominion for the purpose of [illegible] any ship which [illegible] damaged by running aground.

The dock is capable of dealing with some of the largest [illegible]

[illegible]

has ever been built in the British Isles, can be better understood from the fact that it will accommodate ships having 100 feet beam, whereas the length is immaterial due to the dock having open ends.

The works are to be situated at Maisonneuve, Montreal, on the banks of the St. Lawrence River; they will cover an area of over 30 acres, including a basin of 12 acres, and will have a quay frontage of 2,500 feet, and it is estimated that 2,000 men will be employed. At this point the river is over one mile wide.

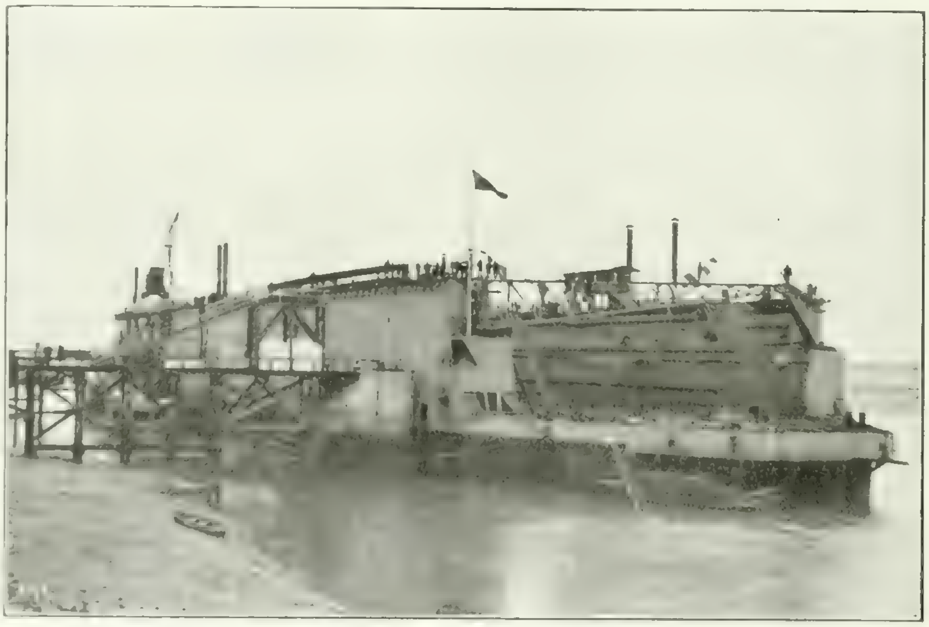
The Harbor Commissioners have offered excellent railway facilities.

On completion of the ceremony the Canadian Ministers made a tour of inspection of the works of Messrs. Vickers, Ltd., and had the opportunity of going inside some submarines.

The company then gathered together at the office when speeches were made by Sir Trevor Dawson, the Hon. J. D. Hazen, Hon. C. J. Doherty, and Mr. C. G. Ballantyne (representing the Montreal Harbor Commission.

The dock is capable of taking the largest existing ship in the British Navy and the heaviest ship trading to Canada.

The building of such a dock has been preferred to the construction of masonry or concrete graving dock, because, although normally it will be utilized within the basin of the new extensive and well-equipped ship-building works of the firm at Montreal, it can be towed to any point on the Atlantic freeboard of the Dominion, to assist in the raising of any ship which may get damaged by running aground, and, in view of the hazards to which the Royal naval and merchants ships are exposed, this will confer very considerable advantage. A feature in the design, too, has been the aim to economize in the working of the dock; thus, although it is capable of taking the heaviest ships afloat, it will more frequently be used for vessels of quite moderate size, and on such occasions it will not be necessary to use the whole of the dock or to run the machinery at its fullest power. In structural details, everything has been done to make the dock continuously reliable. One instance alone need be mentioned: steam heating is provided to prevent water in the compartments from freezing and to preclude the machinery from becoming affected by frost. This is most important because the dock may have to be sunk under a ship in the most severe winter weather, and it is imperative that the water in the compartments [illegible] required. All the [illegible] in the dock [illegible] in duplicate, and [illegible] to facilitate the docking of a ship.



View of the New Floating Dock for Montreal.

The length of the dock is 600 feet, and the width over all 135 feet, the depth of the pontoons at the bottom being 17 feet, while the side walls rise to a height of 42 feet from the pontoon deck, so that the over-all depth is 59 feet. Ships of 100 feet beam can easily be docked, and as the ends are open, a vessel of any length can be accommodated. There are bridges at both ends, for the conveyance of workers. The dock will mark an important development in Canada's association with naval defence as well as in merchant shipping. The name of "Duke of Connaught" has been given to it.

It may be added that the Canadian Shipbuilding and Engineering Works of the Vickers Company are situated at Maisonneuve, a township adjoining Montreal, on the banks of the St. Lawrence. The works, which cover an area of over 30 acres, also include a basin of about 12 acres, having a quay frontage of 2,500 feet, and, when fully working, will employ over 2,000 men. The site is admirably situated and the land has been in a great measure reclaimed from the bed of the St. Lawrence, which, at this portion, is over one mile in width, and the dredging has considerably increased the depth of the river channel where it passes the works. Excellent railway facilities have been afforded by the Montreal Harbor Commissioners. The general construction of the buildings is such as to suit the climatic conditions of Canada, where there is such a vast difference in the temperature of the seasons, and was only decided on after the Canadian Vickers Company had sent their representatives there to study the general conditions, in association with the Montreal architects and contractors. Generally the buildings will be constructed of steel framing, the sides instead of being covered with corrugated sheeting, as is the usual practice in British yards, will be formed of brick, which besides being warmer during winter should be cooler during the summer months. The building berths are so arranged that vessels up to 1,000 feet in length can be built. In the meantime, a covered berth has been erected, so that the work may not be stopped during the winter months. The directors of Canadian Vickers Limited, are:—Albert Vickers (chairman), Sir A. Trevor Dawson, Sir Vincent Caillard, F. Orr Lewis (president Canadian Board), Sir H. Montague Allan, Preble MacIntosh, James G. Lewis.

After the ceremony at the dock, the Minister of Marine and the general company of guests made a long tour of inspection of the most important departments of the Vickers works under the guidance of the directors of the company.

The party included:—The Hon. J. D. Hazen and Mrs. Hazen, the Hon. C. J. Doherty, Miss Doherty, Mr. G. J. Desbarets, Admiral and Mrs. Kingsmill, Mr. and Mrs. C. G. Ballantyne, Mrs. R. C. Smith, Mr. MacArthur Smith, Mr. J. T. Hackett, Dr. Hackett, Mr. G. Heidmann, Mr. and Mrs. F. Orr Lewis, Mrs. Grant, Mrs. W. Beardmore, Col. John Hughes, Miss McKeard, Mr. and Mrs. James R. Nelson, Mr. C. B. Reilly, Mr. B. W. Gonin, Mr. Nugent M. Clougher.

◆

NEW RUSSELL MOTOR FACTORY.

The Russell Motor Car Company are building an addition to their plant, consisting of a four-story machine shop, equipped with the latest machinery for automobile manufacture. The cost of the building will be approximately $100,000. This increase to the plant of the company will result in the employment of about 200 more skilled workmen, and bring the total number of employees to over 1,200. The company has now completed and occupies its new office building.

NEW METHOD OF TESTING RIVET STEELS.*

By G. Frémont, Paris.

(Translated by C. Salter, London.)

In order to avoid serious errors in calculating the strength of materials, prudence demands that one should take as a basis only the lowest elementary strengths indicated by experience, and in addition apply a sufficiently low coefficient of safety.

Thus, as regards the strength of riveted members, it is usual in calculating to allow only for the shearing strength of the rivets; but in practical construction work it is essential that riveted members should act solely by the adhesion of the plates, and never merely by the resistance to shearing of the rivets, since, in the latter event, these undergo gradual shearing and soon wear out. The same applies to receptacles which have to keep staunch: boilers, tanks, etc., because if there is insufficient adhesion they become leaky.

When engaged in experimental investigations on riveting I was led to isolate each of the factors influencing the holding power of the rivet; and in order to study the influence of the elastic limit of the metal, forming the rivet, on the adhesion strength, I devised in 1904 a new method of determination based on the rotary slip around the rivet, the latter serving as axis. I used plates with unworked surfaces, which gave different results at each test.

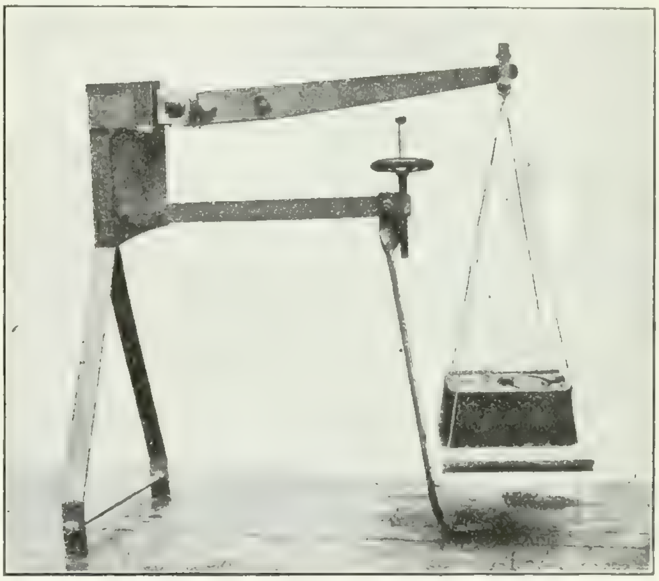


Fig. 1.—Machine for Measuring the Adhesion Produced by a Rivet.

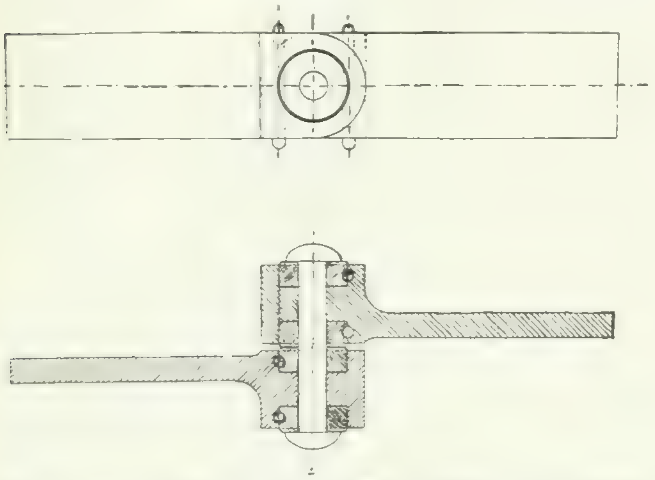
The Western Railway Company of France was good enough to prepare plates for me in which the thickness of the metal was reduced beyond the confines of the circular surfaces, concentric with the rivet, which alone were to remain in contact under the pressure of the rivet; but the finish and roughness of the natural surfaces of the plates, varying in each test, prevented me from ascertaining the influence of the elastic limit of the metal of the rivet, and in November, 1905, I was obliged to publish the first part of my report without giving the results of these tests. My failure was due to the mistake I made in following the conditions of practice; and since then the only way in which I have been able to obtain a satisfactory result has been by working with sliding surfaces that could be easily brought into uniform condition in all cases.

---

* Paper to be delivered at sixth Congress of the International Association for Testing Materials.

These results, moreover, have merely a relative value, since they were obtained with worked, uniform sliding surfaces, but they vary solely under the influence of the effective grip of the rivet. For this it is sufficient that my apparatus should provide—as can easily be done—a smooth cylindrical hole for the insertion of the rivet.

The results of my experiments have been published in a paper on the strength of riveted members ("De la résistance des pièces rivées") in the Bulletin de la Sté. d'Encouragement, April, 1909.



Figs. 2 and 3.—Cheeks of the Testing Machine Connected by the Rivet the Grip of which Produces the Adhesion.

Strength of adhesion being the predominant quality in the case of rivets, it is necessary to ascertain the adhesion that the metal is able to give under certain definite conditions.

For carrying out these adhesion tests I have designed a small machine which is shown in Fig. 1.

I have described it as follows[1]):—Two members, provided with cheeks (Figs. 2 and 3) are connected by a rivet, 16 mm. in diameter, of the metal under examination. The total thickness of metal held by the rivet is 100 mm. The bearing pieces between the cheeks, and between the latter and the rivet heads, consist of four cylindrical tool-steel washers, turned, tempered and polished, in order to obtain sliding surfaces which can be accurately reproduced in all cases with ease.

The effort of adhesion is ascertained by the aid of weights which are placed on the platform at the end of the lever until slip is produced between the contact surfaces be- [illegible]

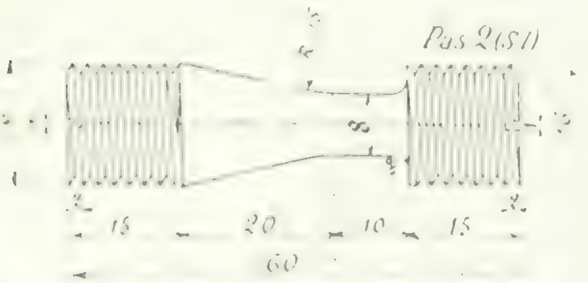


Fig. 4.—Truncated Test Piece for Tensile Test with Determination of the True Elastic Limit.

[illegible]

distance between the axis of the rivet and the knife edge of the balance is 0.594 m.

These data enable the moment of resistance to be calculated.

The value of the effort of adhesion per square millimetre of sectional area of a rivet 16 mm. in diameter is P 0.2.

P is the load formed by the weights placed on the platform, plus the weight of the lever itself, which in this instance is 2.850 kilos.

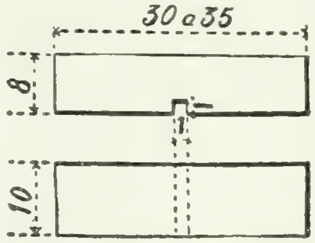

Fig. 5.—Nicked Prismatic Test Piece for the Impact Bending Test.

A screw stop, operated by a small handwheel, limits the travel of the lever, and enables several slip tests to be performed in succession.

In these tests it is important to standardize the method of riveting the specimen of steel; and the conditions must be less favorable than those occurring in practice.

After the adhesion test the rivet is taken out by removing one of its heads, and the metal is tested. The thickness of the rivet shank: 100 mm., enables a test piece to be prepared in the shape of a truncated cone (Fig. 4) for the tensile test with determination of the true elastic limit, and a prismatic test piece (Fig. 5) 8 x 10 mm., nicked with a saw cut, for impact bending tests to ascertain the brittleness or toughness of the metal.

◆

SOME CONSIDERATIONS IN THE CHOICE OF A PAVEMENT.*

By Prof. Leonard S. Smith, University of Wisconsin, Madison, Wis.

What is the best pavement? is a question which citizens, city officials and even some engineers are not infrequently guilty of asking, forgetful of the plain fact that such a question admits of no ready or simple answer. As well might it be asked what is the best bridge or the best house to build. It is a most hopeful sign that the past year has seen many papers read at engineering society meetings discussing this question of considerations affecting the choice of a pavement.

It cannot be too emphatically stated that in each case the best structure for a pavement depends upon the particular service required of it and also, too, upon the widely varying local conditions. These modifying factors naturally divide themselves into two general classes. The first of these govern the conditions to which the pavement will be subjected. Chief among these factors are the quality, nature and even the direction of the traffic, the character of the district served by the pavement, the grade of the street and the presence of car tracks.

On the other hand, the second class of factors which may determine the selection have reference to the character of the pavement itself, such as durability, smoothness, noiselessness, slipperiness, cost, etc.

The best pavement for some particular street, then, would be the one which would give the greatest and most needed service, using the word service in a broad way. The limits of this paper will not allow of a full discussion of this [illegible] question, but my point can be most clearly explained by giving a few applications of the principle. For example, if the street had a steep grade, all such considerations as smoothness, noiselessness, cost, etc., must needs give way to the single governing quality of non-slipperiness. Again, if the street in question were on a moderate grade in a high-class residence district or in the office-building district of a large city, the factors of smoothness and noiselessness might properly determine the final selection. Such a selection, while involving a very expensive pavement, has repeatedly been shown to fully justify itself by the added value and earning capacity of the property. As a third example, considering the choice of a pavement in a wholesale district, subject to concentrated heavy traffic, the qualities of durability and non-slipperiness would here naturally receive the greatest consideration.

---

* A paper read before the Engineering Society of Wisconsin.

The above statements are so obviously based on common sense that it may seem to some useless to take up valuable time in their presentation. Repeated inspection of the pavements in a score of our largest cities has shown the writer that the choice of pavements has too frequently been left to chance or prejudice. Our growing vision of municipal efficiency discerns a much-needed reform in the choice of our pavements, a reform certain of realization.

But while there is great economic need that the best fitted pavement for each particular street should be thoughtfully and carefully chosen, it is at least of equal importance that all such paving improvements should proceed in accordance with some well-considered plan—some comprehensive system for future improvement of the entire city, ward or region. For example, pavement improvements should be so planned as to provide several parallel routes for through traffic. If this be not done, the single route becomes congested and the pavement is prematurely worn out. Again, pavements should be continuous, both for the convenience of traffic and for ease of maintenance.

In the case of country highways, it is necessary to construct disconnected stretches of pavement, but even here it it of prime importance that such construction should proceed in accordance with a systematic plan, so that disconnected stretches may eventually become a part of a complete system. For example, in our own State it would be easy to select a few trunk roads leading from the metropolis of the State to the adjoining cities, and still others connecting the largest city or county seat of each county, as being certain to attract the heaviest traffic. Portions of such trunk roads should be improved with reference to sustaining heavy traffic and also with a view of becoming a part of an intra-state system.

Unhappily the city paving program is too often determined by the ward politician or the opposition or favor of short-sighted real estate owners. A few cities which have tried this plan of adopting a paving program extending over ten years will soon occupy an enviable position. Our cities cannot do better in this respect than to follow the example of the most successful railroad companies.

While future traffic conditions may render necessary here and there a change in the detail plan, the city is certain to gain largely in the end because of having a carefully prepared plan for all street improvements, including water, sewer and gas as well as pavements.

The charter of many American cities provides that the abutting property owners shall pay for the first pavement, while the city must pay for all repairs and renewals. As might be foreseen, this has resulted in the selection and construction of many cheap and inferior pavements, where much more permanent construction would have been justified. But this abuse has not stopped here. Long time bonds have been commonly issued to secure the payment of such temporary pavements, in many cases falling due twenty-five years or more after such pavement has utterly worn out.

Such a system of financing pavements cannot be characterized as anything short of dishonest. It simply transfers to the backs of our children the burdens we of right should bear ourselves. For the future will doubtless have sufficient burdens and problems of its own without being required to shoulder in addition those of to-day.

Already legislatures are considering corrective legislation. The writer knows of at least one eastern legislature which in 1910 passed a law prohibiting a city from paying for short-life pavements out of the proceeds of any bond sales. This principle of "pay as you go" deserves a wide adoption.

It is worthy of restatement that cheapness does not necessarily mean a cheap price of the pavement when laid; indeed, such a pavement may likely prove the most expensive in the end. The other governing elements which determine the actual cost of a pavement are the annual cost of repairs and the term of life of the pavement. Permanent pavements may properly be paid for out of the proceeds of bond issues payable during the life of the pavement. In such cases the public will eventually have to pay for the following items: Interest on the bonds, cost of repairs and annual sums for a sinking fund, which by the time the pavement is worn out will pay off the bonds. Such a plan may be shown by the following formula:

$$S + CI + \frac{R}{L} = \text{annual cost,}$$

where S = the yearly amount put in the sinking fund
C = first cost of the pavement
I = the rate of interest
L = the life of the pavement in years
R = the total cost of repairs.

Obviously, the cheapest pavement is the one involving the least annual cost. If, for example, macadam pavement be chosen for a street having traffic, the last term $\frac{R}{L}$ would be so large as to make such a pavement the most expensive type that could be chosen. This fact is an added illustration of the importance of a wise selection of a pavement for the traffic conditions.

New York State for several years has been making the colossal mistake of issuing many millions of long-time bonds in payment of some form of macadam even on heavy traffic trunk highways, where they very frequently have failed after a comparatively short term of service. Such is the judgment of well qualified engineers who have had charge of the construction and maintenance of such roads. The seriousness of this situation will not be fully realized until after the officials responsible for this error have passed to their final reward. Other States nearer home have made similar mistakes.

The construction of some form of the macadam road fulfills at a minimum cost all reasonable demands on streets or country highways carrying a moderate traffic, especially if such roads have the added protection of continuous maintenance. This class includes over half of our country roads.

But if such improved highways happen to connect two or more large cities, the unusually heavy traffic which such a road at once attracts results in certain and speedy failure. The advent of automobile and other forms of motor traffic, while it has lengthened the life of hard city pavements, has been the chief cause of the destruction of macadam roads.

The seriousness of this problem of the choice of proper road material is realized when we reflect that the demands made by this new form of motor traffic are certain to greatly increase in the near future. Highway engineers of every land are looking for an adequate remedy, but so far with only partial success. While constructional methods in nearly all other lines of engineering have been satisfactorily perfected and standardized, we find present highway construction on main trunk roads grossly inadequate for even the traffic of to-day, thereby causing needlessly large charges for maintenance.

It has seemed to the writer that real progress would be made by breaking away entirely from macadam construction on heavy traffic main highways. The improved and more permanent construction best suited to replace the macadam on such roads will here again be largely a local question. Ohio, Indiana and Pennsylvania have taken the first steps toward satisfying the demand for a more permanent construction by building many hundreds of miles of brick pavements laid on a concrete base with a cement grout filler, all supplemented usually by wings of dirt, gravel or macadam. The expense of such a pavement, about $1,000 per foot of width per mile, does not exceed the average price paid by New York State for its wider but short-life macadam roads, while the brick roads, if properly constructed, promise to be in good condition twenty-five years hence.

Wayne county, Michigan, has constructed a good many miles of main highways, leading out of Detroit, of rich concrete, seven inches thick, at prices which also compete with eastern macadam, while giving promise of outlasting the latter by many years. Where the proportion of automobile traffic is not too great, a large amount of traffic has generally been economically provided for by some form of the bitulithic construction. It may be that Wisconsin, with her widely distributed rich deposits of good gravel and other road materials can wisely follow one or all of these forms of permanent construction. Few States are more favorably situated for road building than Wisconsin. We are fortunate also in being able to profit by the experiments of our older sister States. These have shown us that there is no one best pavement and no one best way of constructing it under all circumstances.

We now recognize that the selection of road material and the method of incorporating it into a road is in large part a local question; in fact, that highway construction in city and country obeys the same rules of procedure as do all [illegible]

◆

GRAND TRUNK PACIFIC AFFAIRS

In view of the misleading reports in the daily press respecting Grand Trunk Pacific affairs, Mr. E. J. Chamberlin, president of the road, has issued the following statement:—

"The Grand Trunk Pacific Railway have been operating [illegible] Railway between [illegible] 1911, [illegible] The Government [illegible] the Grand Trunk Pacific execute a permanent lease of that portion of the line [illegible] between the Government and the Grand [illegible] Transcontinental, [illegible] between Moncton and Winnipeg, which was to be constructed by the Government and is known as the eastern division, provides that:—

" 'Pending the completion of the eastern division by the Government the company shall be entitled to lease from the Commissioners to be appointed under the said act, and to operate such portions of the eastern division as may from time to time be completed, upon such terms,' etc., but does not bind the railway company to take over any sections unless they desire to do so, until the entire line is completed.

"Negotiations are in progress between the Government and the company relative to a further lease of the section above referred to when it is fully completed and pending the completion of the whole line. Notwithstanding reports in the papers throughout the country, that portion of the Transcontinental line is not yet completed. There is considerable work to be performed on the entrance into Winnipeg, connecting up the Transcontinental with the Grand Trunk Pacific and the Canadian Northern at the Union Station. There is also considerable other work on the line necessary to be done before the terms of the contract are complied with.

"With regard to the Springfield, or Transcona shops: Major Leonard, chairman of the Transcontinental Railway Commission, has decided that the shops are not part of the contract between the Government and the railway, while the company contend that they are part of the Transcontinental contract. If Major Leonard's contention is eventually sustained, the taking over of the line between Winnipeg and Lake Superior Junction would not include the taking over of the shops by the Grand Trunk Pacific Railway. On the other hand, if the Grand Trunk Pacific's contention that the shops are a part of the Transcontinental Railway is sustained, the taking over of the line would also mean the taking over of the shops and placing them promptly in operation."

◆

LAKE ERIE AND NORTHERN RAILWAY COMPANY.

At a meeting of the directors of the Lake Erie and Northern Railway Company, an agreement was concluded with Messrs. G. W. Farrell and Company for the purchase of the entire issue of $1,100,000 5 per cent. mortgage bonds.

The Lake Erie and Northern Railway was incorporated by a special act of the Federal Parliament in May, 1911.

The Dominion Government has granted a subsidy of $6,400 per mile, or a total grant of approximately $340,000.

The charter provides for the construction of an electric railway from Port Dover on Lake Erie through the towns of Simcoe, Waterford, Brantford and Paris, to the town of Galt, a distance of 53 miles. Connections will be made at Galt with the main line of the Canadian Pacific Railway for an interchange of traffic on completion of the road.

The directors of the company comprise a number of the prominent manufacturers in that district and consist of Messrs. John Muir, Harry Cockshutt, Lloyd Harris and John Sanderson, of Brantford; Richard Thompson, general manager of Penmans, Limited; F. H. Deacon, of Toronto; Martin Todd, general manager of the Galt, Preston and Hespeler Railway, and G. W. Farrell, of Montreal.

Mr. Lloyd Harris, one of the directors of the Lake Erie and Northern Railway Company, stated this week that the directors will call for tenders at once and hope to have construction started this fall.

The towns through which the line will pass—Galt, Paris, Brantford, Simcoe, Waterford to Port Dover—have voted to take second mortgage bonds totalling $500,000.

The directors believe that the field is a most promising one for both freight and passenger business, the 53 miles through which the line will pass being thickly populated.

METHODS OF TESTING CLAY.

A report on the clay and shale deposits of the Western Provinces has recently been printed for the Federal Department of Mines. In this report the authors, Heinrich Rieo and Joseph Keele, give their method of ascertaining the physical qualities of these substances. A report compiled by the following methods is of value in ascertaining the commercial aspect of the raw material. Their method consisted of a determination of plasticity; water required for mixing; tensile strength; air shrinkage; fire shrinkage; color and absorption at different temperatures; and fusing point.

Tensile Strength.—The determination of the tensile strength of the raw material is made because it gives a clue to the clay's ability to stand strains in handling before burning, and possibly also of its bonding power or its ability to stand the addition of non-plastic materials like sand or "grog."

The clays and shales submitted to the physical tests were first thoroughly dried, then ground in a jaw crusher and afterwards sifted through a 20-mesh sieve.

A weighed quantity of the sifted material, sufficient to make the necessary number of test pieces, was mixed with just enough water to give it the greatest plasticity, and thoroughly kneaded and wedged so as to render it perfectly homogeneous and free from cavities. The consistency generally arrived at was about midway in stiffness between a soft-mud and stiff-mud brick in practice.

In making briquettes for the tensile test a small piece of the kneaded clay was clamped into the briquette mould, and struck by the hand until it filled the mould completely, the excess of clay being struck off by a fine wire.

The clay was removed from the mould on a dry clay briquette—a set of them being kept for the purpose—and the wet clay briquette was not handled until it had hardened on its support, so that they were not distorted while soft.

The briquettes when hard were dried to 100° C., the cross section at the waist carefully measured, and then broken in an ordinary tensile strength machine.

Shrinkage.—All clays shrink more or less in drying and burning. The shrinkage that occurs while the clay is drying is termed air shrinkage, while that which occurs during the burning is known as fire shrinkage.

Air Shrinkage.—A portion of the kneaded clay was made into bricklets in a mould 4″ × 1½″ × ¾″ in size. Two fine lines, exactly 3 inches apart, were impressed with a steel stencil on the wet clay bricklet immediately after leaving the mould. When the bricklets were thoroughly dry the distance between these lines was measured, and the percentage of air shrinkage calculated.

Fire Shrinkage.—The burning of the bricklets at the lower cones was done in a down-draft muffle kiln, the fuel used being coke, and the time of burning from 12 to 18 hours. For the higher temperatures a gas-fired muffle kiln was used.

The lines on the burned bricklets were again measured after each successive firing, and the total amounts of shrinkage calculated. The difference between the total shrinkage and the air shrinkage represents the fire shrinkage.

Fusibility.—Small pyramids or cones of the ground clays or shales were burned in the gas-fired furnace until they were deformed or melted (Fig. 1). The temperatures at which the test cones melted are expressed in terms of the standard Seger cones.

A Deville furnace, fired with coke, under air blast was used for determining the fusing points of the more refractory clays, including those which did not fuse until a temperature ranging from cone 18 to cone 32 was reached.

Absorption.—The bricklets were carefully weighed after each burning, and immersed in water to about three-fourths of their thickness. This permits the air from the burned clay body to escape freely, allowing the water to better and more quickly fill the pores. After standing at least 24 hours in water, the saturated bricklets are weighed, the increase in weight recorded, and the percentage of absorption calculated as follows:—

$$\frac{\text{Saturated weight—dry weight}}{\text{Dry weight}} \times 100.$$

Dry-Press Tests.—The clay or shale used for the dry-press test was ground to pass a 20-mesh sieve, and moistened with 5 to 10 per cent. of water. A mould was filled with the damp clay, and pressed in a hand screw-press, the size of the bricklet produced being 4″ × 1½″ × 1″.

Rapid Drying.—For this test the clay or shale was ground to pass a 12-mesh sieve, and kneaded up with sufficient water to a fairly stiff mass, from which a full-sized building brick was made by hand in a wooden mould.

Immediately after coming from the mould the moist brick was placed on a rack in a box open at the bottom and with a perforated top, which stood on a steam-heated radiator. The temperature in this box ranged from 120° to 150° F., which is the heat usually attained in artificial dryers. If the brick cracked under this treatment it was understood that it would not stand rapid drying.

Drying Defects in Certain Clays.—Various Tertiary clays, and some Cretaceous shales found in Alberta and Saskatchewan, have the serious defect of checking while drying.

Clays of this character are usually very fine grained and highly colloidal, absorbing a large percentage of water when tempered for wet moulding. They are exceedingly plastic and sticky when wet, becoming a stiff, soap-like, and sticky mass, which is hard to work.

Generally, within half an hour after leaving the moulds fine cracks appear at the edges of the brick, which quickly spread over the surfaces, and as drying progresses these cracks widen and deepen. In time the outside of the brick becomes bone-dry, but the inside may remain quite moist for several days.

In some clays the cracks which developed in drying closed up completely when the drying was ended, but reappeared again in the burned product.

Several of the clays that displayed this drying defect gave fairly low air and fire shrinkages, were somewhat refractory, and burned to a good, hard body at cone 1.

In several districts they were the only materials available, and, as they might turn out to be sewer-pipe or paving brick clays, it was very desirable to devise some practical method of treatment to make them workable.

Hitherto, whenever brickmakers had to deal with clays which were too "fat" or "strong," as they termed those claps which were highly plastic, they usually added from 10 to 25 per cent. of sand. The sanded clays were found to dry quicker and work easier; the air and fire shrinkages were reduced, and generally a good, burned product is obtained from the mixture.

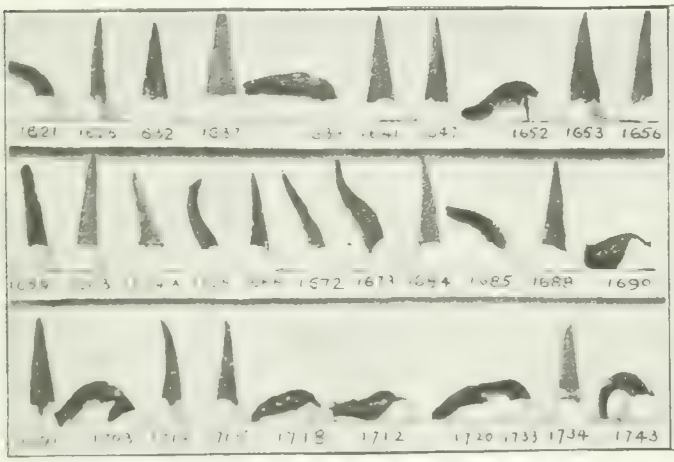
Apparently, then, the proper remedy to cure the objectionable behaviour of the clays being dealt with was the addition of sand. But when 25 per cent. of sand is added to these clays they crack quite as badly as before. They can be dried with the addition of 40 to 50 per cent. of sand, but this amount is evidently in excess of the bonding power of the clay, because the burned brick made from such a mixture is altogether too porous and weak for any purpose whatever.

It was then found by experiment that if any of these clays be ground and calcined or burned to a red heat, that the calcined clay, which has lost its plasticity, can be added to the raw clay in quantities as large as desired to secure the best working quality; that drying at a moderately fast rate can be accomplished with safety, and the properties of the burned clay body are not affected.

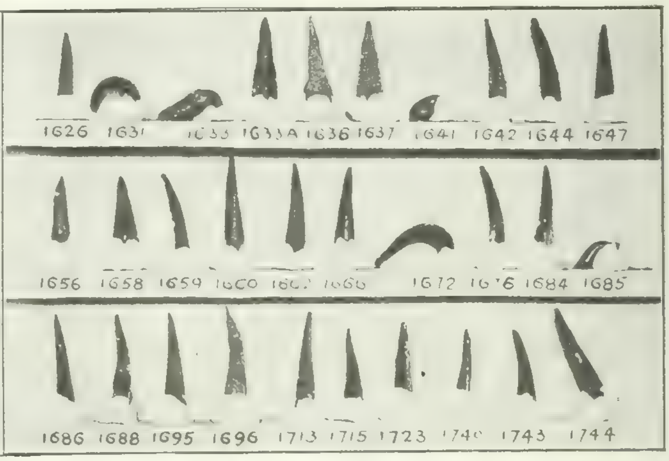
The calcined clay, then, acts as sand during the early stages of manufacture, but when burned it proceeds towards vitrification with the raw clay, and does not remain inert at ordinary burning temperatures as sand will.

Further experiments on preheating clays shows that if the ground clay be heated from 300° to 500° C. that they lose a great deal of their plasticity, and the quality of the clay is changed from a tough, sticky mass when melted to a granular and easily worked body which can be moulded by the stiff-mud process, and will stand fast or moderately fast drying.

How extremely finely divided some of these clays are in the raw state and the change in texture they undergo in preheating is shown in the following mechanical analysis, made by the centrifugal method:—



Pyramids of Clay after Heating to Cone 1.



Pyramids of Clay after Heating to Cone 3.

(The figures under each refer to the laboratory numbers.)

[illegible]

Further experiments were undertaken with certain substances [illegible]

Of the various materials tried for this purpose during [illegible] be cured by the addition of 1 to 2 per cent. of hydrochloric acid to the mixing water, or 1 to 2 per cent. by weight of common salt added to the dry clay. The salt seemed to be the most practical, and was used in the greater number of tests.

The amount of water required for tempering the clay was reduced by about 10 per cent. by the addition of salt. The water appeared to convey the salt from the body and deposit it at the surface in a slight scum, but this generally disappeared in burning.

The bricks so treated dried perfectly in about four days at a temperature of 70° to 80° F., but would not stand fast drying.

The object of preheating any clay is to overcome drying difficulties, and the temperature required to accomplish this object varies with different kinds of clay. The amount of heat necessary for some clays would destroy the plasticity of another clay and render it useless for moulding.

In some cases while drying can be carried on safely after preheating, the burned wares may show a tendency to crack, but such clays generally work perfectly when dry pressed.

The temperature used in calcining clay must be sufficiently high to deprive the clay of all plasticity and reduce it to a condition resembling sand. Although this operation requires a higher temperature than preheating with the object of destroying only a portion of the plasticity, the operation is a simpler one because critical temperatures are not observed.

Clays to which salt is added frequently show a slight glaze when burned to cone 1, but the quality of the body does not seem to be affected, especially if the clay is somewhat refractory. The use of salt appears to be detrimental to some of the more easily fusible clays.

No difference was detected in the burned wares made from clay treated with hydrochloric acid.

It is hoped that a more complete investigation will follow the preliminary work already done, but the manufacturer having drying trouble with his clay will probably overcome it by adopting after trial the method which is best suited to his particular case.

◆

The Canadian [illegible] Company have increased their capital by the [illegible] of preferred stock. The company will increase its Toronto plant by the erection of a new factory, and make other extensions.

STANDARD SPECIFICATION FOR REFRACTORY MATERIAL.

At the recent meeting of the Institute of Gas Engineers of Great Britain, the Refractory Materials Committee presented their annual report, which includes a standard specification for silica bricks, blocks, tiles, etc., which has been drawn up by the committee in collaboration with representatives of the Retort and Firebrick Section of the Society of British Gas Industries, together with several other leading makers of this class of material.

The specification has been prepared upon the basis of the results of tests undertaken by Dr. J. W. Mellor, D.Sc. (Principal of the Staffordshire County Pottery Laboratory), who acted as technical adviser to the committee. In presenting the specification the committee state that, owing to the almost entire absence of authentic tests and results on a working scale of silica and siliceous material, the specification must not be regarded as final, and that revision will be made from time to time as experience is obtained. The following is a copy of the specification referred to:—

Section 3.—Silica Bricks, Blocks, Tiles, etc.

The material covered by this specification is divided into two classes:—

(1) That containing 92 per cent. and upwards of silica, and hereinafter called "silica" material.

(2) That containing from 80 to 92 per cent. of silica, and hereinafter called "siliceous."

Refractoriness.

1. Test pieces of the material shall show no sign of fusion when heated to the following temperatures:—

"Silica" material—not less than Seger cone 32 (about 1,710 deg. C.).

"Siliceous" material—not less than Seger cone 29 (about 1,650 deg. C.).

The test shall be carried out in an oxidizing atmosphere, the temperature of the furnace being increased at the rate of about 50 deg. C. per five minutes.

Chemical Analysis.

2. A complete chemical analysis of the material is to be provided when required by the engineer (or purchaser) for his personal information only.

Surfaces and Texture.

3. The material should be evenly burned throughout and the texture regular, with no holes or flaws. All surfaces shall be reasonably true and free from flaws or winding.

Contraction and Expansion.

4. A test piece, when heated in a gas muffle or electric furnace to a temperature of Seger cone 12 for two hours shall not show, on cooling, more than 0.75 per cent. linear contraction or expansion. The temperature of the furnace shall be maintained constant throughout the testing period; and the test piece shall be at least 4½ in. long by 4½ in. wide—the ends being ground flat, and the contraction or expansion measured by means of Vernier callipers reading to 0.1 mm.—a suitable mark being made on the test piece, so that the callipers may be placed in the same position before and after firing. The test samples shall not be taken out of the middle of a brick, block, or tile, but shall be representative of the whole.

Variations from Measurements.

5. In the case of ordinary bricks, 9 in. by 4½ in. by 3 in. or 2½ in. thick, there shall not be more than ± 1½ per cent. variation in length, nor more than ± 2½ per cent. variation in width or thickness; and in all cases the bricks shall work out their own bond. Special bricks, blocks, or tiles shall not have more than ± 2 per cent. variation from any of the specified dimensions.

Cement Clay.

6. This shall be machine ground, and at the discretion of the manufacturer may contain a suitable percentage of fine grog. But in all cases the cement clay shall be quite suitable for the purposes of binding together the bricks, blocks or tiles for which it is supplied, and shall be capable of withstanding the same test for refractoriness.

Inspectioon and Testing.

7. The engineer (or purchaser), or his agreed representative, shall have access to the works of the maker at any reasonable time, and shall be at liberty to inspect the manufacture at any stage, and to reject any material which does not conform to the terms of this specification. Pieces representative of the bulk may be selected for the purpose of testing either before or after delivery; but in every case a representative of the maker shall, if he choose, be present when such selection is made, and shall be supplied with a similar piece of the material to that taken for the purpose of testing.

Any complaint as to quality of material to be made by the purchaser before the expiration of ten days after delivery.

If the engineer (or purchaser) and the maker are not prepared to accept each other's tests, they shall agree to submit the samples for testing to an independent authority, to be mutually agreed upon; and the engineer (or purchaser) reserves to himself the right, if the material does not conform to the tests laid down in the specification, to reject any or all the material in the consignment from which the test pieces were taken.

The cost of these independent tests, and of any bricks, blocks, or tiles, damaged before delivery for obtaining test pieces, shall be equally divided between the purchaser and the maker, if the test proves satisfactory; and if unsatisfactory, such cost, and that for all other subsequent tests required on this account from the same consignment, shall be borne by the makers.

The cost of any tests of or any material damaged for the purpose of obtaining test pieces after delivery shall be borne by the purchaser in the event of the test being satisfactory, and, if unsatisfactory, by the manufacturer, in a similar manner to that specified for the tests prior to delivery.

APPENDIX AND NOTES.

Refractoriness.

Clause 1.—For general remarks and suggestions for testing, also table for softening temperatures of Seger cones, vide appendices of Sections 1 and 2. The cones should in all cases be placed relative to the sample, so that both are subjected to the same temperature.

Contraction or Expansion.

Clause 2.—For general remarks, vide appendices of Sections 1 and 2. As soon as cone 12 has squatted, it ceases to furnish any further indication of the temperature of the muffle; so that the subsequent temperatures should be ascertained, at about 15-minute intervals, by means of a pyrometer. It is essential, however, that the temperature should be maintained constant; and if it is necessary to remove plugs, etc., for the purpose of obtaining the temperature, great care must be taken to avoid cooling the furnace by such means. As in the test for refractoriness, the cone should be placed in such a position relative to the sample under test, that both may be subjected to the same temperature.

Inspection and Testing.

Clause 7.—It has been pointed out by the representatives of the manufacturers that, owing to the high cost of carriage, they may be involved in serious loss if material is extensively condemned after delivery. They agree that the purchaser must have entire freedom to test, and reject, if necessary, any material delivered to him; but it is suggested that until all the manufacturers have suitable arrangements and appliances for constantly testing their goods, it may be possible to render them some assistance by allowing a fairly large sample of their material to be sent in for testing and general approval before extensive deliveries are made. This is in no way, however, to be construed as removing the right of the purchaser to test material in any subsequent consignment.

GASOLINE RAILWAY MOTOR CARS.

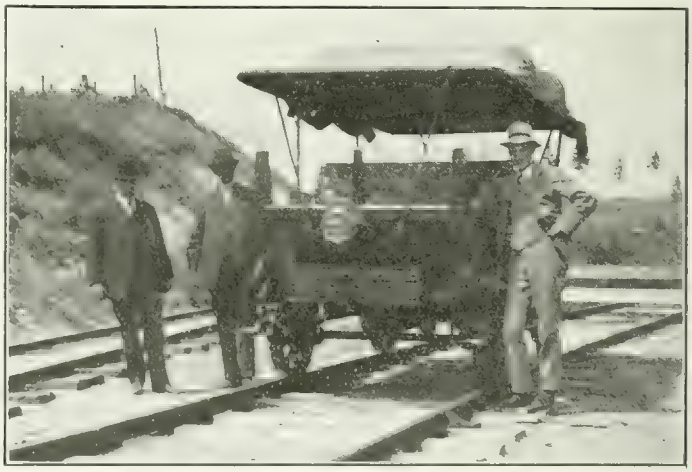
A new type of gasoline railway motor car has recently been introduced into this country by the Drewry Car Company, Limited, of London, England. This firm manufactures railway motor cars of various types, which they have supplied to over ninety railways in all parts of the world. One of their directors is now in Canada on a visit, and has brought with him a 20 horse-power car to carry six passengers. This car is one of the Drewry Company's most popular models, and is fitted with a four-cylinder water-cooled engine and a three-speed gear and reverse, giving all the speeds in both directions. Two sets of control are provided, one at each end of the car, and the seats are reversible. This enables the driver to sit in the front, and the passengers to face the direction of travel in whichever way the car may be running. This is one of the special features of the car, and entirely obviates the use of a turntable. The body is comfortably upholstered, and is fitted with a Cape cart hood and side curtains, and a folding wind-screen at each end. The car is well sprung, and is fitted with heavy steel wheels and axles, which make for steady running at all speeds.

By the courtesy of the Canadian Pacific Railway a demonstration was recently given on this car, which we illustrate, from Montreal to Mont Laurier and back, a total distance of 316 miles. This is one of the most difficult sections of the road, having a considerable length of 2½ per cent. grade and a large number of short curves. The grades were all taken on top gear at over twenty miles per hour, and on the level the car gave a speed of fifty miles per hour, while at the same time it is capable of running at a [illegible] per hour, which greatly facilitating track inspection. At the high speeds the running is wonderfully steady, and the railway engineers who were [illegible]

[illegible]

will be found interesting. He reported in part as follows:—

"In many different parts of the world I have heard railway engineers complain of the difficulty in finding a thoroughly satisfactory type of automobile for inspection purposes, and even the most experienced among them have hitherto failed to secure what they want in this respect. Upon the Paraguay Central Railway I have come across what seems to be as perfect and as satisfactory an automobile as has yet been introduced. This is a reversible, six-seated Drewry car, type "K." The car referred to is 16 horse-power, and it has been running now for some six months at an average of 90 to 100 miles a day. Upon numerous occasions it has attained and maintained a speed of 90 kiloms., say, 56 miles an hour. Both the owner, the chairman of the Paraguay Central Railway, and the chauffeur speak enthusiastically of the car and the work which it does. I have travelled many miles over roughly-laid temporary track in this Drewry car, and I must add my testimony to that above quoted, since it would be difficult to find a smoother-running or a more admirably-built automobile than this."



Drewry Railway Motor Car.

The above referred to a similar car to the one herein described. Various models are marketed, ranging from a light car of 4 horse-power to seat two up to cars of 40 and 50 horse-power to carry forty passengers.

Their business in Canada is being handled by Messrs. Peacock Brothers of 68 Beaver Hall Hill, Montreal, and No. 406 Dominion Trust Building, Vancouver, who will be pleased to give anyone interested further particulars.

HOOPS FOR WATER TANKS.

Round iron hoops for wooden water tanks are advocated as preferable to flat hoops, in the report of a committee of the American Railway Bridge and Building Association. Wrought iron is considered as the best material for this purpose, and is more easily obtained in this form than in flats. One argument in favor of the round hoop is that fully 90 per cent. of its surface is exposed to view, hence deterioration is more easily discovered and painting is more effective. Objections to the use of the round hoop are raised on account of its small bearing surface against the staves and the ledge offered by the upper surface for the accumulation of dirt and moisture. The report states that experience has shown that if properly placed the small bearing surface does not induce crushing of the fibre, and suggests the caulking of the round hoops with oakum and filling the top space with roof cement to obviate the second objection.

LAYING SUBAQUEOUS WATER MAINS AT ROME AND MERIDIAN.*

By M. L. Worrell, General Manager, Meridian Waterworks.

While Superintendent of Public Works at Rome, Ga., the writer had three crossings to construct, one through Silver Creek and two through the Etowah River. The creek was to be crossed close to a highway bridge, and it was deemed preferable to lay the pipe on the bottom of the creek rather than to suspend it from the bridge, or to lay it on the floor, on account of the sudden rises and heavy floods in the stream. The creek was 60 ft. wide between banks at the street level, 40 ft. wide at low water, and, at ordinary low water stage, was 12 ft. deep.

Ten-inch cast-iron pipe with the John F. Ward flexible joint was used. It weighed about 87 lb. per foot or 1,034 lb. per section of 12 ft., and cost 2 cents per pound delivered in Rome. The limit of deflection of this joint is said to be 15 deg., though experience at Rome indicated that it was not safe to use the limit, 12 deg. being safer.

The line of five 12-ft. lengths was made up on a platform spanning the creek at the street level and then lowered by tackle into the stream, the two ends being kept clear of the water for later joining to the water mains on each side of the creek. The submerged part was gradually lowered, thus allowing deflection, until it rested on the bottom. The pattern of the Ward bell and spigot being different from the design of ordinary cast iron pipe, the two were connected by short pieces designed by the consulting engineer, Mr. J. N. Hazlehurst, who was in responsible charge of both engineering and construction.

After the Ward pipe was attached to the street main a test for leakage showed a loss of 28,000 gal. per day of 24 hours. This being excessive, a diver was sent into the water, who discovered that the limit of safe deflection had been exceeded, causing three lead joints to leak very badly. The creek line was detached at each end and raised. All joints were recalked, the bottom of the creek partially filled with small boulders to reduce the deflection of the joints to about 12 deg. and the pipe again lowered and tested. The next test showed a leakage of about 380 gal. per day. Later this joint was again calked and the leakage reduced to about 150 gal. per day. The pipe was covered with boulders and no trouble has since been experienced with it.

The cost of this work approximated $300, everything included, or $5.00 per lineal foot.

The first river crossing was at a point where the banks rose about 40 ft. above low water. A wire cable was stretched from bank to bank, to which trolleys for carrying the supply boat and pontoon raft were attached. The pontoon for laying the pipe in the river was constructed as shown in the diagram. The flotation was provided by 25 empty oil barrels lashed together with ½in. manila rope, the barrels being laid in three rows with a "slot" in the middle row at the stern of the raft. The wood-work was so left as to make it easy to transfer the "slot" from the rear to the front.

Two trolleys with the necessary tackle were attached to the wire cable and secured to the raft, and a supply boat was attached to the cable almost immediately beneath it, this boat carrying extra lengths of pipe, pigs of lead, yarn, melting pot, etc. The pontoon carried nothing but a tripod of 2-in. wrought iron pipe supporting a triplex block for handling the pipe. The outfit was moved across the river by a hand rope.

The first joint was secured to a dead-man on the bank by a heavy chain. The outfit was pushed off, the bell of the pipe being forward, the second joint fitted in and calked, the outfit moved forward again with the next pipe, and this was repeated until the other bank had been reached. The "slot" was then moved to the front end of the pontoon by removing a part of the deck and the short row of five barrels to the stern, thus leaving the last joint of pipe ready for attachment to the forward shore of the river and to the ordinary 10-in. cast iron pipe.

The short joints of pipe for joining the Ward with the ordinary cast-iron pipe were made to lay 3 ft. One had a standard bell on one end and a flexible joint bell on the other and one had a standard bell and a flexible joint spigot.

After the laying was completed two joints on each end of the river pipe were fastened by heavy hog chains to deadmen permanently constructed in the banks.

Before pipe laying was begun the river bottom was sounded. It consists of solid rock, slaty limestone, with three ledges running longitudinally, each ledge having practically the same elevation. These ledges were notched with dynamite and the pipe while being laid was fitted in the notches. These notches secured the pipe from deflection downstream.

The length of this river crossing was 216 ft. and the time required for preparation and actual laying was about 6 days. The work was done under a construction superintendent, who also performed the duties of foreman, a straw boss or gang foreman and five laborers and one water boy, the pipe laying cost being about 35 cents per foot. This particular job cost about $700 all told.

The second river crossing was made with 12-in. pipe. The river was somewhat wider and deeper; no notches in rock had to be cut and no channel to be prepared. The cost was approximately $900. It required less time than the first on account of the experience gained then. The work was done when the river was at the lowest stage known for years. The people were saved upward of $3,000, a waterworks contractor, who had done similar work in Rome, though pursuing a different method, offering to do the work, no material included, for $3,500, the cost of material being approximately $1,200, including equipment.

On each side of the streams through which the pipes were laid valves were placed for cutting off the crossings in case of emergency, and it was by by-passing these valves that it was possible to make the tests heretofore mentioned. One valve at each crossing was enclosed in a manhole, into which was tapped the main on each side of the valve, the inlet tap being ¾ in. and the outlet tap 1 in. Lead connections were attached to the taps and the other ends connected to a sensitive 1-in. meter, thus by-passing the valve which, with the other across the stream, was shut off. The water was turned on at the ¾-in. inlet tap slowly and as slowly let out at the outlet 1-in. tap. As soon as the meter and outlet connection had filled the meter ceased to operate, apparently showing that there were no leaks in first river crossing. The meter was removed and examined, replaced and the line tested with the same result. Both river crossings were tested quarterly with the same results during the writer's service in Rome.

The writer has recently completed another crossing through a stream at Meridian, Miss., by a method entirely different from that at Rome. The two reservoirs at Meridian are some two miles from the city, and it was in laying a 20-in. cast-iron pipe to bring more water to the city that the stream was crossed. The elevation of the bottom of the reservoirs is only 5.4 ft. above the bottom of the settling basin in the city, the elevation of the top of the dam, at high water in the reservoirs, being only 16 ft. above the top of settling basin. Therefore it was absolutely necessary in order to secure the greatest flow to select a route as near to a straight line as possible and to avoid anything like a summit or high point on it. With this in view it was deemed advisable to bridge Sowashee Creek, which had to be crossed, on the way to the city. Upon opening bids for the work the prices named were almost prohibitive, and, besides, great danger was apprehended during flood seasons when the stream carries large quantities of driftwood. The writer was therefore directed by the Meridian Water Commission to devise a safe plan for crossing under the stream.

---

*Paper read before American Waterworks Association.

The route selected has only one turn, an angle of 56 deg. made by laying the pipe at a radius of 270 ft. At the creek there was a downward deflection of approximately 20 ft., the total length of the depressed section being 500 ft. Sowashee Creek carries quite a large amount of sand and has a tendency to fill and widen rather than to narrow and scour. At ordinary winter height it is 30 ft. wide and 9 ft. deep at the crossing.

The writer conceived the idea of using a beam trussed like a freight-car sill, upon which to lay the pipe in saddles, the beam to be 36 ft. in length and 3 ft. wide. The work was started by placing across the creek two house-moving truss beams, secured from a local contractor. The commission's beam was rolled across on top of them, and on it was assembled the pipe, consisting of four joints of ordinary 20-in. Class A cast-iron pipe, one blow-off tee, with a spigot end 6-in. blow-off valve attached. Everything was put together with regulation joints of yarn and lead, and the pipe was secured to the truss beam by U bolts bent to a 22-in. radius and cast-iron washers. The entire bridge was then lowered 4.5 ft. beneath the surface.

Before doing this, however, notches were cut in the banks of the creek of the required depth to allow the beam with its load to rest upon the solid earth on each side. In order to prevent the pipe from filling with sand a large barrel head was fastened in each end. The lowering of the load, an approximate weight of six tons, was successfully accomplished by the use of two gin-poles and two capstans. After clearing away the rigging and beams the water of the creek was dammed at each end of the pipe with sand bags and the two ends joined to the main pipe line.

In order to attain security six creosoted piles in three bents have since been driven, each bent being capped with an oak timber, well seasoned, and the original construction suspended from these bents with U bolts. The piles were driven in the bottom of the creek as far as they could be sunk, some 12 ft., the upper ends sawed off flush with the topped the pipe, the creek having in the meantime fallen several feet, and the capping attached by means of 100-d spikes, generally used in bridge construction. The method used allows the water to pass both above and beneath the pipe. It appears to be strong and is absolutely rigid in every direction. The banks have been secured by driving, in crescent shape, two rows of Wakefield piling into the earth as far as they could be driven, some 10 ft. or more.

WORK ON THE GRAND TRUNK PACIFIC.

The Board of Railway Commissioners has made an order allowing the Grand Trunk Pacific to operate the new Tofield-Calgary branch as far as Trochu, [illegible] miles south of Tofield. [illegible] Tofield has already reached Calgary, and steel [illegible] miles [illegible] beyond Trochu.

[illegible] progress in track laying is being made on the several branch lines of the Grand Trunk Pacific, over 11 miles of the [illegible] having been laid in two days last week.

RAILWAY EARNINGS.

The following are the railroad earnings for the week ended July 21:—

	1911.	1912.	Increase or Decrease.
C. P. R.	$2,120,000	$2,593,000	+ $473,000
G. T. R.	960,016	1,047,951	+ 87,933
C. N. R.	337,000	426,100	+ 89,100
T. & N. O. R.	37,066	30,441	— 6,625
Halifax Electric	5,262	5,628	+ 366

The following are the railroad earnings for the week ended July 31:—

	1911.	1912.	Increase or Decrease.
C. P. R.	$2,170,000	$2,701,000	+ $531,000
G. T. R.	1,339,472	1,544,003	+ 204,531
C. N. R.	427,700	575,000	+ 147,300
T. & N. O. R.	47,833	41,374	— 6,459
Halifax Electric	7,591	7,440	— 151

The official figures on the fiscal year of Canadian Pacific Railway ended June 30 show gross earnings of $123,319,541, and net of $43,298,243.

These compare as follows with last year:

	1912.	1911.	Inc.
Earnings	$123,319,541	$104,167,808	$19,151,576
Expenses	80,021,298	67,467,977	12,553,321
Net profits	43,298,243	36,699,830	6,598,412

The heaviest monthly gross receipts were for April, May and June, when they exceeded $11,300,000, the only other month approaching these figures being October, 1911, when they ran as high as $11,200,000.

The smallest monthly gross was $7,328,781 in January.

In four months of the fiscal year the net earnings exceeded $4,000,000. These were August, October and December, 1911, and April this year.

The gains in gross over the preceding year ranged from $733,872 in September to $2,629,325 in April, and gains in net went from $5,848 in September to $1,239,150 in February.

The company's figures for June and the fiscal year are as follows:—

	June 1912.	July 1st to June 30, 1912.
Gross earnings	$11,311,397.20	$123,319,541.23
Working expenses	7,464,794.51	80,021,298.40
Net profits	3,846,602.69	43,298,242.83

In June, 1911, the net profits were $3,024,671.05; and from June 1st to June 30th, 1911, there was a net profit of $36,699,830.57. The gain in net profits over the same period last year is therefore, for June, $821,931.64; and from July 1st to June 30th, $6,598,412.26.

The Canadian Northern traffic earnings and expenses for the month of June, with comparisons, are as follows:—

	June, 1912.	June, 1911.	Inc.
Gross earnings	$1,769,500	$1,465,000	$303,000
Expenses	1,347,800	1,147,400	200,400
Net earnings	421,700	318,200	103,500
Mileage in operation	4,207	3,608	599

For the year ended June, 1912, earnings and expenses compare as follows with the previous year:

	June, 1912.	June, 1911.	Inc.
Gross earnings	$19,538,600	$15,199,500	$4,339,100
Expenses	14,422,500	11,033,700	3,388,800

TENSILE TESTS OF SPLICES OF REINFORCING BARS.

In constructing the walls of the Washington Street tunnel in Chicago the method of drifting by successive levels necessitated the introduction of vertical reinforcing rods of short lengths, cut according to the height of the drift. The walls were built underground and in sections six or eight feet high.

As it was not deemed prudent to rely entirely on the bonding strength of the concrete to transmit stress from one rod to another, tests were made under the direction of the Board of Supervising Engineers on 1-in. twisted steel rods spliced with one or more simple V‘ clamps. These were placed in tension and the load applied at the rate of 1,000 lbs. per minute. As the keys left in the concrete face of each drift allowed a minimum of 8 ins. overlap, this length of splice was used in all tests. A description of the tests is given in the third annual report of the Board of Supervising Engineers, from which we abstract this information

Methods of Testing.—The tests were made with one, two and three clamps as follows:—

(1) Single clamp 8 ins. overlap.

(2) Two clamps fastened on opposite sides.

(3) Three clamps, two fastened on one side and one from the opposite side.

The result showed that in general the two-clamp type was the best to use in construction work. This type, when the clamp was tightened enough—slightly enough to bend the plate—showed a resistance of 6,400 lbs. with ⅛-in. slip. When put under further load there was no movement until the load reached 13,690 lbs., when a sudden slip occurred of 3/16 in. in the strap of one of the clamps and ⅛ in. slip in the rods. The rocks then began to pull apart at this or a lower stress.

The single clamp allowed the bars to twist practically as soon as any stress was applied, and showed a slip of ⅛ in. at 4,000 lbs. stress, increasing to ¼ in. slip at 5,600 lbs.

With three clamps a slip of ⅛ in. occurred in the bars with a stress of 6,760 lbs. The strap started at 10,730 lbs., 11,690 lbs. and 18,330 lbs., respectively, with a total slip at this time of ¼ in. At 25,580 lbs. there was a sudden slip of the bars and one clamp became entirely loose so that no further load could be applied.

In general, the tendency of this type of lap splice is to offer a fairly uniform resistance to tensile stress up to a point where the clamps become dislocated and lose their grip, when complete failure occurs. The effect of tension on the unconcreted joint also appears to hasten the dislocation of the clamps, and consequently decreases the apparent strength of the plain joint.

The working stress used in all concrete designs provided for 16,000 lbs. per square inch tension in the steel. In these tests the resistance was about 7,000 lbs. up to the first slip. This resistance, however, would be much greater when the rods were embedded in concrete, so it was decided to use a splice of the type with two clamps and rely on the bonding stress of the concrete to supply the deficiency between the resistance of the splice and the stress in the steel.

In estimating this additional strength two forces were relied on: First, a surface adhesion taken conservatively at 100 lbs. per sq. in., which directly augments the net tensile strength of the splice; second, a bonding effect, which prevents the bars from twisting, and consequently defers the displacement of the clamps. By this method the full tensile strength of the bar (16,000 lbs.) could be realized.

In various drift levels the key was about 12 ins. in depth, which always provided at least 8 ins. overlap as previously stated. This made it fairly easy to apply the clamps in position.

A second series of tests as indicated on Fig. 2 were made as follows:—

(1) With a two U-clamp splice with ½-in. plate and no concrete.

(2) Two U-clamp splices embedded in a concrete block and tested when the concrete block was seven days old. (Two tests.)

(3) Two U-clamp splices as above, except with concrete 28 days old.

The first test on the plain joint was in the nature of a check on the previous tests, and a maximum of 27,000 lbs. was reached with the first slip at 8,810 lbs. and a total slip of 2¼ ins.

The mixture of the concrete was 1:2:4 with Portland cement, sand and ½ to ¾ in. crushed limestone. The blocks were each 12-in. cubes, thus embedding the 8-in. lap splice 2 ins. at each end, and in this respect the test could not hope to reveal the full bonding strength of a continuous concrete monolith.

The points of measurement of slippage between bars was necessarily outside the cube, so that the combined effect of unrestricted torsion and stretch in these outer sections of the bars undoubtedly decreased the ultimate strength of the joint as put under test, so that the results here recorded may be regarded in every respect as conservative.

The first seven-day cube took a slowly increasing load up to 23,080 lbs., when a movement of ⅛ in. occurred and the concrete cracked on four sides. No further load could be applied until the total slip increased to ¼ in., from which the load was carried up to a maximum of 31,220 lbs. with continual slipping and a total displacement of 1.29 ins. The second seven-day cube failed practically the same as the first, except that the first slip occurred at 19,400 lbs., and a maximum of 34,120 lbs. was carried with a gradual slipping of 1.33 ins.

The test on 28-day concrete showed a slight movement at 13,550 lbs., holding to 21,000 lbs., and then a gradual stretch up to a maximum of 30,480 lbs. with 3/32 in. total slip. In Fig. 2 a vertical movement represents stress without slip, and conversely, inclination represents a continuous pulling apart with increasing load.

Conclusions.—(1) In all cases the strength of the splicing seems to be dependent upon the strength of the concrete, and there is comparatively little margin between the first evidence of distress and complete failure.

(2) The 28-day concrete specimen took about 50 per cent. more stress at complete failure than the average of the two seven-day specimens.

(3) When such splices are used, the concrete would fail before the splice.

(4) This method of splicing reinforcing bars is safe for a working stress of approximately 16,000 lbs. per square inch in the steel.

Figure 2 shows the curious fact that the three-clamp splice without concrete has less strength than the two clamps at lower loads, but as higher loads are applied the third clamp becomes effective. This anomaly is undoubtedly due to the difficulty of securing an equal bearing between bars and clamps until sufficient load has been applied to start abrasive action.

◆

PERSONAL.

MR. JAMES A. BELL, engineer of the township of Dunwich, Ont., has resigned his position and MR. A. S. COLE, O.L.S., has been appointed as his successor.

MR. ALLEN HAZEN, of New York, will oversee the construction of a duplicate filtration plant for the city of Toronto.

MR. J. R. TODD, A.M. Can. Soc. C.E., has taken charge of a new branch office of the John Galt Engineering Company recently opened at 615 Pender Street, Vancouver, B.C.

MR. WILLIAM McGEORGE MASON has been appointed by the council as chief engineer of the city of Prince Rupert, British Columbia.

COMING MEETINGS.

THE WESTERN CANADA IRRIGATION ASSOCIATION.—Sixth Annual Convention Kelowna, Okanagan Valley, B.C., August 13, 14, 15 and 16, 1912. Secretary, Normon S. Rankin, P.O. Box 1317, Calgary, Alta.

CANADIAN GAS ASSOCIATION.—Fifth annual convention will be held in Toronto, August 24th to Sept. 9th, 1912, during the Exhibition. Secretary, J. B. McNary, 90 Caroline St., North Hamilton, Ont.

THE UNION OF CANADIAN MUNICIPALITIES.—August 27, 28 and 29. Meeting at City Hall, Windsor, Ont. Hon. Secretary-Treasurer, W. D. Lighthall, K.C.

CANADIAN FORESTRY ASSOCIATION.—Convention will be held in Victoria, B.C., Sept. 4th-6th. Secy., James Lawler, Canadian Building, Ottawa.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Second Annual Meeting to be held in Toronto, Sept. 16, 17 and 18.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Annual Assembly will be held at Ottawa, in the Public Library, on 7th October, 1912. Hon. Sec'y, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

EIGHTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.—Opening Meeting, Washington, D.C., September 4th, 1912. Other meetings, Business and Scientific, in New York, beginning Friday, September 6th, 1912 and ending September 13th, 1912. Secretary, Bernhard G. Hesse, Ph. D., 25 Broad Street, New York City.

INTERNATIONAL ASSOCIATION FOR TESTING MATERIALS.—Sixth Congress will be held in the Engineering Societies Building, 29 West Thirty-ninth Street, New York, Sept. 2-7, 1912 Secretary, H. F. J. Porter, 29 West Thirty-ninth Street, New York.

ILLUMINATING ENGINEERING SOCIETY.—Sixth Annual Convention to be held at Hotel Clifton, Niagra Falls, Ont., Sept. 16-19, 1912. Secretary, Preston S. Millar, 29 West Thirty-ninth Street, New York.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Ninth Annual Convention will be held in Cincinnati, December 3, 4, 5 and 6, 1912. The Secretary, 150 Nassau St., New York.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE · Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—[illegible] W. D. [illegible]; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, Mr. Hugh B. Fergusson, 409 Carter Cotton Bldg., Vancouver, B.C. Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; [illegible] P.O. Box [illegible]

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-jack. Meets every first and third Friday of each month, October to April, in [illegible]

MUNICIPAL ASSOCIATIONS

[illegible] MUNICIPAL ASSOCIATION.—President, Mayor [illegible] Hamilton [illegible] St. Thomas, Ontario.

[illegible] ASSOCIATION OF RURAL MUNICIPALITIES.—[illegible] Hinsley, [illegible]

[illegible] ASSOCIATION.—[illegible]

THE UNION OF CANADIAN MUNICIPALITIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., [illegible]

THE UNION OF THE [illegible] MUNICIPALITIES.—President, [illegible]

UNION OF [illegible] MUNICIPALITIES.—President, [illegible] N.S.

[illegible] MUNICIPALITIES.—President, Mayor [illegible]

UNION OF [illegible] MUNICIPALITIES.—President, Mayor [illegible] B.C.

[illegible]

[illegible]

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewit, General Manager Consumers' Gas Company, Toronto; J. B. McNary Secretary, 90 Caroline St., North Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President, J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Jas. Anderson, Gen. Mgr., Sandwich, Windsor and Amherst Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, A. F. Wickson; Toronto. Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. M[illegible]; Secretary, H. [illegible] Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Hon. W. [illegible], Minister of Lands, B.C. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. [illegible], P.O. Box [illegible], Winnipeg, Man. Second Monday except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on for reference only, unless otherwise noted, at the office of he Canadian Engineer, 62 Church Street, Toronto:—

ids close — Noted in issue of
31—Trenching and Backfilling, Edmonton, Alta (S.) 8-8

(Canora specifications are also on file at the office of The Canadian Engineer, Rooms 617-628, Transportation Building, Montreal.)

◆

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

TENDERS.

Bassano, Alta.—Tenders addressed to George Bond, Secretary, Bassano, will be received till August 22nd, 1912, for the supply and delivery of 2,400 lineal feet of six-inch to twelve-inch steel pipe, or alternatively, eight hundred tons cast-iron pipe, fifty gate valves, sixteen hydrants. Specifications, etc., at the office of the Engineers, the John Galt Engineering Company, at 317 Portage Avenue, Winnipeg, and Vancouver. (See advertisement in The Canadian Engineer.)

Brantford, Ont.—The Lake Erie and Northern Railway Company will soon call for tenders and commence construction work this fall. Lloyd Harris, of Brantford, Ont., and F. H. Deacon, of Toronto, are interested in the project.

Chatham, Ont.—Tenders addressed to Z. Paul, Commissioner, Croton Post Office, will be received up to August 19th, 1912, for the erection of a concrete pier and steel bridge, known as the Prangley Pap Bridge. Plans and specifications can be seen at the residence of Mr. Z. Paul, Lot 4, Con. 11, Camden Gore.

Edmonton, Alta.—Tenders are invited for the erection of an 8-room addition to the Rutherford School, Edmonton South, to be delivered up to noon of August 22, 1912, at the office of the Edmonton Public School Board, Mortlake Block, Edmonton, Alta. George E. Turner, building commissioner, where plans and specifications may be obtained.

Guelph, Ont.—Tenders will be received from all trades up to Tuesday, August 13th, for making certain alterations and additions for the Royal Bank of Canada at Guelph. Particulars at the offices of Messrs. Colwill, Tanner & Co., architects, Traders Bank Building, Guelph, Ont.

Hamilton, Ont.—Tenders addressed to R. L. Lathan, chief engineer, Toronto, Hamilton and Buffalo Railway, will be received up to noon August 17th next for depositing earth or other suitable filling on certain lands of the above company. Plans may be seen at the office of the engineer or from the agent at Brantford, Ont.

Imperial, Sask.—Sealed tenders will be received by J. G. Hobman, secretary-treasurer, village of Imperial, Sask., up to Tuesday, Aug. 20th, 1912, for the construction of a waterworks system. Plans, specifications and information may be obtained from J. G. Hobman, secretary-treasurer, Imperial, Sask., or at the office of Smith and Ross, engineers, room 4, Peart Block, Regina.

London, Ont.—Tenders will be received at the office of the City Clerk until August 22nd, 1912, for the construction of 5,812 square yards of bituminous-top macadam pavement on a five-inch concrete base, with 3,985 lineal feet of six-inch curb and 15-inch gutter, on Ridout Street, from Horton Street to Elmwood Avenue. Specifications and plans at the office of Geo. W. Wright, City Engineer. (See advertisement in The Canadian Engineer.)

Moose Jaw, Sask.—The city will receive tenders for the drilling of a 3,000-foot gas well in the city of Moose Jaw, and also alternative tenders for the completion of a well which is at the present time drilled to a depth of approximately 1,100 feet, and which it is desired to complete to a depth of 3,000 feet. Further information may be had on application to the City Commissioners.

Moncton, N.B.—Tenders for the new schoolhouse at Georgetown were opened as follows: T. D. LeBlanc, $2,240; Paul Lea Co., $2,190; A. H. Stevens, $2,075. The contract was awarded to A. H. Stevens, he being the lowest tenderer.

Ottawa, Ont.—Tenders will be received at the office of R. C. Desrochers, Secretary, Department of Public Works, Ottawa, until August 26th, 1912, for the delivery of creosoted timber for Northern and Eastern New Brunswick. Specification, etc., at this Department and at the offices of Geoffrey Stead, Esq., District Engineer, Chatham, N.B.; E. T. P. Shewen, Esq., District Engineer, St. John, N.B.; C. E. W. Dodwell, Esq., District Engineer, Halifax, N.S., and G. A. Bernasconi, Esq., District Engineer, North Sydney, N.S.

Ottawa, Ont.—Tenders for the construction of a breakwater in Victoria Harbor, B.C., will be received until September 5th, 1912, at the office of R. C. Desrochers, Secretary, Department of Public Works, Ottawa. Plans, etc., at this Department and at the offices of W. Henderson, Resident Architect, Victoria, B.C.; C. C. Worsfold, Esq., District Engineer, New Westminster, B.C.; J. G. Sing, Esq., District Engineer, Toronto, Ont.; J. L. Michaud, Esq., District Engineer, Montreal, Que.; A. Decary, District Engineer, Quebec, Que., and on application to the Postmaster at Vancouver, B.C. (See advertisement in Canadian Engineer.)

Ottawa, Ont.—Tenders for the construction of a laboratory building, quarantine station, Halifax, N.S., will be received until August 26, 1912. Plans and specifications, etc., can be obtained at the office of Mr. W. Bishop, inspector of public buildings, Halifax, N.S., 53 Spring Garden Road, and at the office of R. C. Desrochers, Secretary, Dept. of Public Works, Ottawa.

Ottawa, Ont.—Tenders addressed to W. W. Cory, Deputy Minister of the Department of the Interior, Ottawa, Ont., will be received up to noon of 20th August, 1912, for the construction of a wire fence around Moose Mountain Buffalo Reserve. P. G. Keyes, Secretary, Department of the Interior, Ottawa. (See advertisement in Canadian Engineer.)

Ottawa, Ont.—Tenders for the erection of a laboratory building, Quarantine Station, St. John, N.B., will be received until August 26th, 1912, at the office of R. C. Desrochers, Secretary, Department of Public Works, Ottawa. Plans, etc., at this Department and on application to Mr. D. H. Waterbury, Superintendent of Public Buildings, Public Works Department, St. John, N.B.

Ottawa, Ont.—Tenders will be received up to noon of September 2nd, 1912, for the construction of a twin-screw steel steamer for Customs service on the Atlantic coast, to be delivered at the port of Quebec, tenders to be addressed to John McDougald, Commissioner of Customs, Department of Customs, Ottawa. Plans and specifications of the steamer can be seen at the Department of Customs, Ottawa, and at the offices of the Collectors of Customs, Toronto, Collingwood, Montreal, Quebec, St. John, N.B., and Halifax, N.S.

Ottawa, Ont.—Tenders for the construction of deep-water piers in the harbor of Quebec, P.Q., will be received until August 21st, 1912, by R. C. Desrochers, Secretary, Department of Public Works, Ottawa. Plans, etc., at the offices of the Secretary; J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto, Ont.; J. L. Michaud, Esq., District Engineer, Merchants Bank Building, St. James Street, Montreal, Que., and A. R. Decary, Esq., District Engineer, Post Office Building, Quebec, Que.

Ottawa, Ont.—Tenders for the construction of a public building at Lethbridge, Alta., will be received at the office [illegible]

Ottawa, Ont. [illegible]

Peterboro, Ont. [illegible]

Tillsonburg, Ont. [illegible]

Toronto, Ont. [illegible]

Toronto, Ont.—Tenders will be received by J. O. Reaume, Minister of Public Works, Ontario, Parliament Buildings, Toronto, up to noon of 30th September, 1912, for the purchase of the Education Department and Normal School Property in the city of Toronto. Conditions of sale, etc., may be obtained at Mr. Reaume's office.

Toronto, Ont.—Tenders addressed to G. W. Lee, General Agent T. and N.O. Railway Commission, North Bay, will be received up to noon of August 28th, 1912, for the purchase of lots in the new sub-division of the townsite of Cochrane, in the District of Nipissing. Conditions of sale, etc., may be had on application either to G. W. Lee or to A. J. McGee, Secretary-treasurer T. and N.O. Railway Commission, 25 Toronto Street, Toronto.

Winnipeg, Man.—The contract for the basement of the new Elmwood Presbyterian church was let to Warwick Brothers. The cost will be $13,000. The estimated cost of the entire building will be about $45,000.

Winnipeg, Man.—At a meeting of the school board the contract for the construction of the new twenty-one roomed school, to be located in Ward Three, was awarded to the firm of S. Brynjolfsson & Co. The tender of the firm was for $122,886. Work will be started immediately.

Winnipeg, Man.—Tenders addressed to M. Peterson, Secretary, Board of Control Office, Winnipeg, will be received up to noon of August 28th, 1912, for the manufacture and delivery, f.o.b. Winnipeg, of one hundred ornamental lighting standards. Specifications, etc., at the office of the Light and Power Department, 54 King Street.

Winnipeg, Man.—Tenders will be received up to noon of August 14th for the electric wiring of the power-house, main and branch tunnels, Agricultural College, St. Vital. Plans and specifications may be seen at the office of the Provincial Architect, 261 Fort Street, Winnipeg. Colin H. Campbell, Minister of Public Works, Winnipeg.

Yorkton, Sask.—Sealed tenders marked "Tenders for laying of outflow sewer," will be received by T. F. Acheson, secretary-treasurer of Yorkton, up to 6 p.m., August 20th next, for the laying of approximately five thousand six hundred (5,600) lineal feet of forty-two inch (42 inch) concrete sewer pipe. Plans and specifications may be obtained from the above. A marked cheque for $500 must be enclosed with all tenders submitted.

◆

CONTRACTS AWARDED.

Province of British Columbia.—Messrs. Culleton Bros., of Spokane, have been awarded an additional five miles of track beyond their ten mile contract north of McBride Junction by the Canadian Pacific Railway.

Mr. J. W. Hoard of Victoria, has been awarded a contract to construct five miles of track south west from Trent River by the Canadian Pacific Railway.

Calgary, Alta. — The Canadian Pacific Railway have awarded a contract for the construction of fifty houses to be used by employees of the company at the Ogden locomotive and car shops. Messrs. Westinghouse, Church, Kerr Company, of New York, will construct this work.

Medicine, Hat, Alta.—The Alberta School Supply Company of Edmonton, have been awarded a contract for the supplying of the interior finish to the two new schools nearing completion in this city. The contract is for 600 desks, chairs, maps, etc.

Montreal, Que. Messrs. Towhy Brothers, railway con [illegible] are required.

Montreal, P.Q. [illegible]

Dolarway
Pavement

"It is permanent because it is concrete."

The Last Word
In Street Pavements

The Dolarway Pavement is popular with City Officials, Highway Engineers and Property Owners because:

It is low in first cost.
Its maintenance cost is lower than that for any other permanent form of Pavement.
No paving plant is required to either construct or maintain it.
It is noiseless, dustless and resilient.
Its traction qualities for both the Horse and the Automobile are of the best.

510 Title & Trust Bldg., Chicago, Ill.

Applying Dolarway Bitumen on Concrete Base, Central Park, N.Y. City.

Moose Jaw, Sask.—High pressure pumps and equipment: Contractors, Messrs. Chapman and Walker, Ltd., 69 Victoria Street, Toronto, $7,900.

Moose Jaw, Sask.—The Saskatchewan Bridge and Iron Works have received an order for much of the steel work in connection with the new power plant now being erected.

Moose Jaw, Sask.—The contract for the remaining 30,000 feet in connection with the Caron water supply, has been awarded to Messrs. William Newman and Co., Ltd., of Winnipeg.

County of Oxford, Ont.—The Hamilton Bridge Company have received a contract to supply and erect a superstructure of a new bridge being built between this county and Waterloo. The cost of the entire bridge will be about $8,000.

Saskatoon, Sask.—Messrs. Frid Lewis & Co., Winnipeg have received a contract to erect a departmental store for F. R. MacMillan & Co. A sprinkling system and a permanent vacuum cleaner are included in the plans.

South Vancouver, B.C.—Messrs. McPhalen Bros., 828 Seventh Avenue East, have been awarded a contract by the Board of School Trustees to erect four school buildings as follows:—Secord school, Victoria road, $36,200; Gordon school, Ferris road, $35,700; Sexsmith school, Sixty-first Avenue and Ontario Street, $35,300; Norquay school, Ferguson road, $35,200.

Victoria, B.C.—The Vancouver Machinery Depot have been awarded a contract to supply and erect the mechanical equipment of the civic coal bunkers at the city yards. The cost of this work is $7,271.

Victoria, B.C.—The contract for the municipal hall at Ladner has been let to Mr. C. G. Bowden, Burnaby Lake, the price being in the neighborhood of $13,000.

Westmount, P.Q.—The tender of R. T. Smith has been accepted by the council for the work of paving Hillside Avenue with asphaltic concrete at a cost of $13,370.

Winnipeg, Man.—The National Meter Co., 318 Dearborn St., Chicago, have the contract for supplying 3,000 5/8-inch water meters to cost $61,878.75. H. N. Ruttan, 223 James Street, is engineer.

◆

RAILWAYS—STEAM AND ELECTRIC.

Saskatoon, Sask.—The municipal council have awarded a contract to the St. Louis Car Company for twelve new single truck street cars at a price of $5,009.25 each, f.o.b. Saskatoon. Messrs. Stone and Webster are engineers to the council in all matters relating to street railway.

[illegible]

GARBAGE, SEWAGE AND WATER.

Fort William, Ont.—Providing that a bond sale is successfully negotiated the council of this city will construct a trunk sewer at a cost of $125,000. The high cost of this work is due to the fact that excavation will have to be carried down 35 feet in many sections. John Wilson, city engineer.

Montreal, P.Q.—Superintendent Lesage has recommended that a new pump be purchased and installed in readiness for next summer.

Moose Jaw, Sask.—The Municipal Commissioners are about to consider tenders on the construction of a high pressure water system. There is included in the plan of this work a large dam on the river below the Manitoba Street bridge. Five firms have tendered on this work.

Vegreville, Alta.—The ratepayers have voted the sum of $82,000 on the installation of a waterworks plant.

Victoria, B.C.—It is probable that temporary financial assistance will be required to complete the enlarged sewage plans of this municipality. Mr. C. H. Rust is engaged on the preparation of an estimate of the cost of this work.

Windsor, Ont.—If the Provincial Health Act is rigidly enforced there will be a large expenditure on a sewage disposal plant in this city. At present the river is employed to carry away the refuse. F. E. Brian, city engineer.

◆

BUILDINGS AND INDUSTRIAL WORKS.

Berlin, Ont.—A report is in circulation in this city to the effect that a milk Pasteurizing plant will probably be established. The names of the interested parties are withheld for the present.

Brantford, Ont.—A branch factory of the Keeton Motors, Limited, will be established in this city. Messrs. Harley and Sweet are interested in the project.

Edmonton, Alta.—The management of the Commercial Hotel have made arrangements for a new building to replace the present wooden structure. It is also their intention to further enlarge the premises by 1913.

Kamloops, B.C.—W. J. Ellis has prepared plans and details for the erection of a new foundry to be built on a site near Ward's garage. Work on the new plant will be commenced at once.

Lethbridge, Alta.—Owing to the recent sale of the Salvation Army Barracks on Fifth Street, that body are preparing to erect a new structure. The new building is to cost about $25,000.

Montreal, P.Q.—The building to be erected by the Mount Royal Garage will be 70 x 200 feet, six stories and basement, steam heating, and will contain a well-equipped repair and machine shop.

Moose Jaw, Sask.—The City Commissioners have been given power to purchase steel for the new power house without the formality of tenders.

Moose Jaw, Sask.—The municipal council have sold a site to the management of the Canadian Swift Company. It is the intention of the latter to erect a distributing plant.

Ottawa, Ont.—A new building, costing in the neighborhood of $50,000, for the Geodetic Survey of Canada, will be erected at the rear of the Dominion observatory at the Experimental Farm in the near future. The plans and specifications are now being prepared by Mr. David Ewart, chief architect of public works.

Outremont, P.Q.—The Bell Telephone Company are preparing to erect an exchange building at this point.

Saskatoon, Sask.—The management of the Quaker Oats Company have decided to erect a separate mill for the manufacture of their oats and not include this branch of the business with the manufacture of flour. This decision will mean an expenditure of several thousand dollars over the original estimates. Mr. John Stewart, second vice-president of the company, has been in Saskatoon in connection with the preliminaries of this work.

St. Thomas, Ont.—The St. Thomas Dehydrator Company has been formed with Mr. John Lyle as president. The plant of the St. Thomas Canning Company has been purchased and machinery will be installed at once for the dehydrating and evaporating of fruits and vegetables of all kinds.

CURRENT NEWS.

Arcola, Sask.—Indications of a valuable coal deposit were found at this point during well drilling operations at the foot of Moose Mountain near this town.

Dunsmuir, B.C.—The Canadian Collieries, Limited, are opening up a new shaft near Cumberland, and expect to strike a seam of coal at 900 feet according to the present borings.

Eastern Ontario.—A company taking the name of the St. Lawrence River Concrete Company has been formed with a view of supplying all the cement and concrete to replace the damage caused by the recent fire at the Thousand Islands. They will do their manufacturing at this point.

Edmonton, Alta.—The Commissioners have received the following tenders for the supply of gas mains steel pipe and specials:—

Gorman, Clancey & Grindley	$90,000 00
Munderloh & Co., Montreal	86,000 00
John Coates & Son	Detailed prices

Edmonton, Alta.—The Commissioners have received an offer from E. Manders for the construction of the special city boulevard at a cost of $13,000.

Montreal, P.Q.—A three-story steel frame building in course of erection at 913 Mount Royal Avenue collapsed and fell into the street.

Fort William, Ont.—Active work on the construction of the New Fort William Elevator Company, grain elevator, is now under way by the contractors, Barnett & McQueen of this city.

Moncton, N.B.—A boiler in use at Well No. 26 at the gas fields on the Petitcodiac River exploded and caused considerable damage to the plant. Mr. Boggs, the manager, will have the remains of the boiler shipped to Moncton to see if repairs are possible.

Province of Nova Scotia.—Coal contracts recently let by the Department of Railways and Canals will go a long way to increase the coal business in Eastern Canada. This supply is for the operation of the Intercolonial Railway. The Dominion Coal Company at Springhill have a contract for over 80,000 tons, the Maritime Coal Company will furnish the People's Road with 75,000 tons, the Minudie Mine 40,000 tons, and a number of other small collieries have also been given substantial contracts.

Ottawa, Ont.—A report states that the Federal Government will create a new portfolio during the coming season. This will be a Portfolio of Mines, and will deal with these matters exclusively.

Ottawa, Ont.—Mr. H. W. White, a prominent landscape artist of Great Britain, will visit this city on the invitation of the Prime Minister and express an opinion on the layout of the proposed government buildings to be erected on the Wellington site.

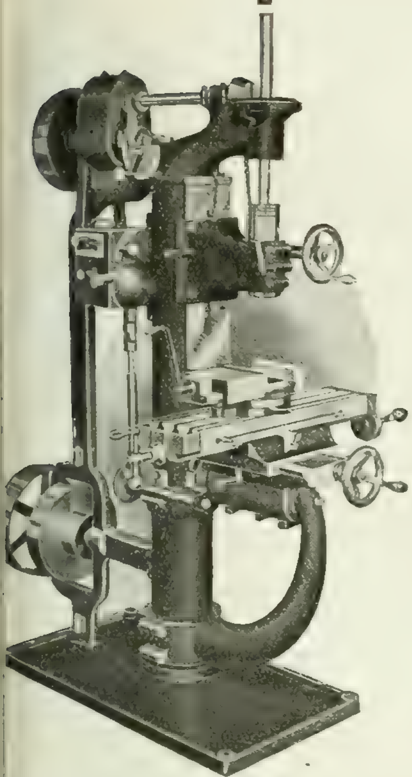
Quebec, P.Q.—Messrs. Sir William Arrol & Company, Limited, of Glasgow and Montreal, have been awarded the contract for the large, new 50-tons wharf crane with which the Harbor Commissioners are equipping this port. Next to the Montreal Harbor Commissioners' 75-tons floating crane, which was also constructed in the works of this company, this machine will be the largest of its kind in Canada, and will fulfil a long felt need at Quebec.

Province of Saskatchewan.—About nine hundred miles of long distance telephone line is rapidly nearing completion.

Stratford, Ont.—Owing to a rise in the price of gravel supplied by private pit owners the municipal council investigated and located a new source of supply in a park owned by the city. The gravel in this part is of a high grade and almost unlimited quantity.

Vancouver, B.C.—A report states that Mr. Charles W. [illegible] of the Maple Leaf Milling Company, has recently examined several suitable sites in this city with a view of estab-

You Need a Machine Like This on a Dozen Different Jobs



It's a No. 2 Knight Milling and Drilling Machine

This machine is very rigid, powerful and accurate, so that close work may be turned out with a high degree of satisfaction, and in the shortest possible time. The adjustments are quickly and easily made. On a large variety of work it is possible to make a saving of from 20 to 50 per cent. in time, as compared with other machines.

The fact that hundreds of Knight Machines are now in use in this and foreign countries proves that they are not experiments.

These machines are made in three sizes.

Briefly, the construction of the No. 2 Knight Miller is as follows :—Spindle of crucible steel, ground bearings ; working surface of table, 29 × 8½ inches ; feed, longitudinal and transverse ; floor space, 60 × 68 inches ; weight, crated for shipment, about 2,500 lbs.

The Canadian Engineer

An Engineering Weekly

THE POWER PLANT OF THE SPANISH RIVER PULP AND PAPER MILLS, LIMITED.

In the issue of *The Canadian Engineer* of June 6th, 1912, there appeared a general description of the plant of the Spanish River Pulp and Paper Mills, Limited. This plant is located at Espanola, on the Soo branch of the Canadian Pacific Railway, forty miles west of Sudbury and one hundred and thirty-eight miles east of Sault Ste. Marie. We herewith present some further data descriptive of the hydraulic and steam power equipment of the plant.

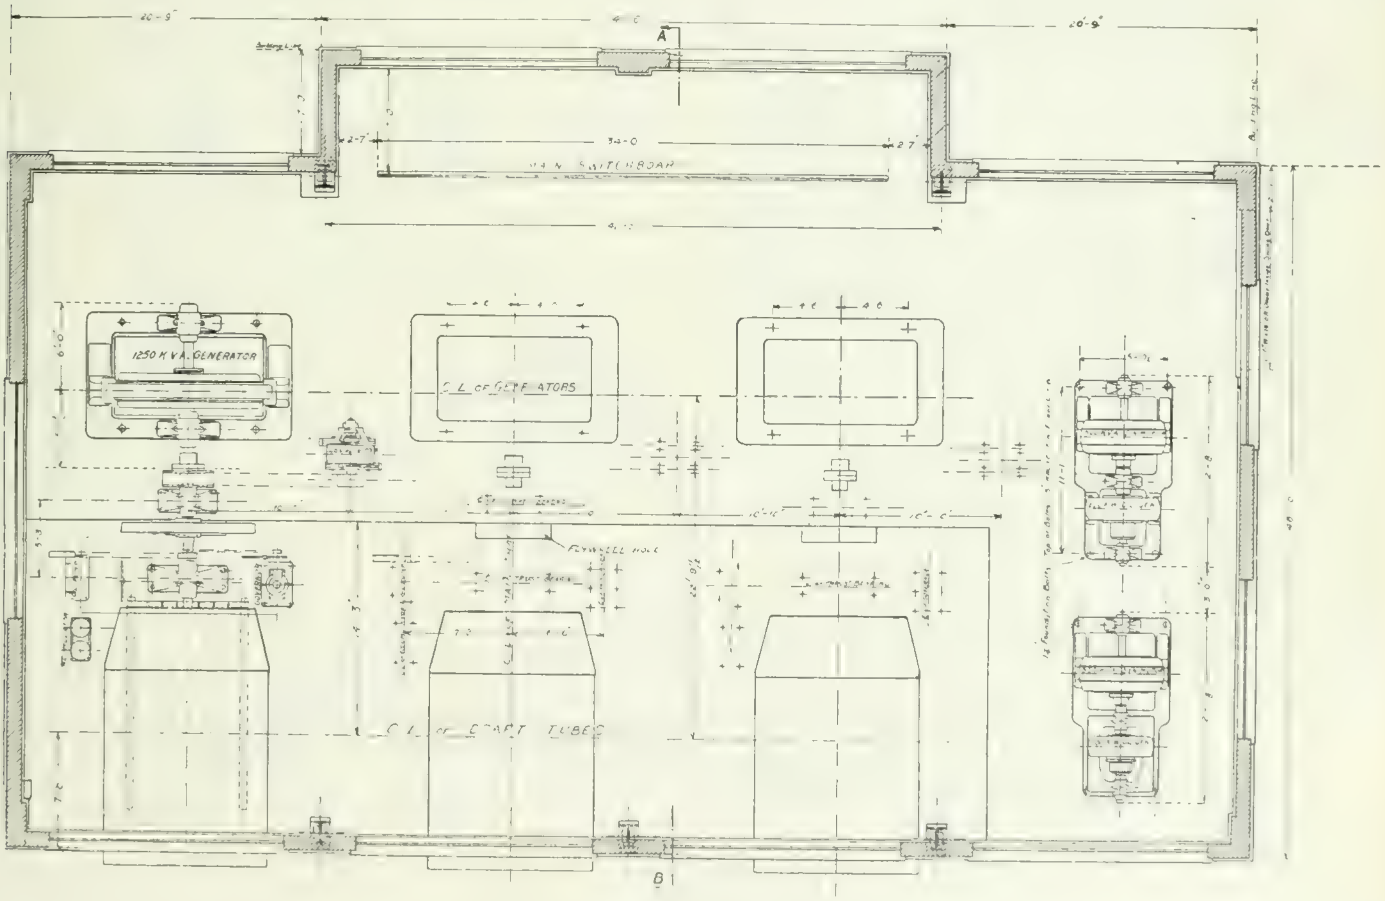

Fig. 1.

The Spanish River runs through the heart of the timber limits owned by this company, which comprise some 6,000 square miles. At Espanola the river runs between two promontories, creating a favorable location for the dam, which is built of concrete, flanked by natural rock formation on either side, and providing a 60-foot head of water. The storage thus provided serves not only to regulate the water supply, but also creates the necessary storage capacity for some 40,000 cords of wood, which it is necessary to prepare during the winter months for supply throughout the year.

Five large penstocks convey water from this dam to the turbines, which supply power for grinding the wood to pulp. A sixth penstock supplies water for three other smaller turbines direct-connected to generators, which supply current for operating the numerous motors used in the various parts of the plant. The five grinder turbines have 2,200 horse-power capacity each. The single penstock, which feeds the turbines driving the generators, is 14 feet in diameter, and on reaching the power-house divides into three sections, one supplying each unit. These three turbine units each consist of two 30-in. diameter Hercules water-wheels, 1,650 horse-power capacity, 360 r.p.m. when operating under the 60-foot head.

The penstock is 275 ft. long, the first 25 ft. being made from 5/16-in. plate, and the rest of 3/8-in. The intake is

12 ft. 2 in. wide and 14 ft. 0 in. high, with arched top. There is a 16-in. vent pipe to prevent collapsing of penstock when emptying, and an expansion joint is placed about half-way down to take care of expansion and contraction due to changes of temperature. Two 6 in x 6 in. angle iron rings are rivetted on the pipe at each end; between these angles a 3 in. x ½ in. anchor stay, ends of which are embodied with the angles in large concrete anchor piers. The upper part of the penstock is carried on cast-iron brackets, which are rivetted to the pipe, and set on concrete piers. The lower section is carried on structural steel, the saddles being carried on a trestle.

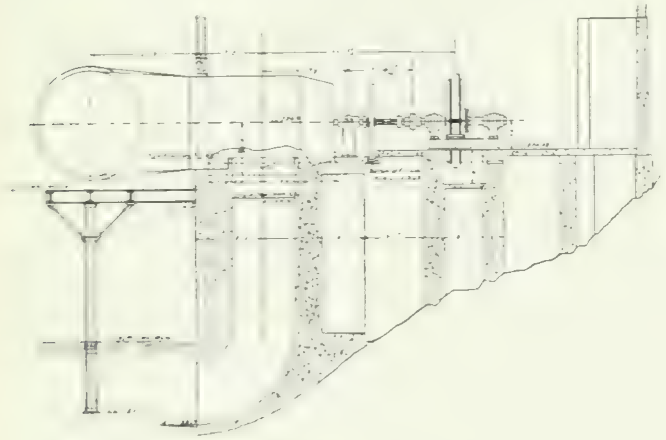

Fig. 2.

Fig. 2 gives a cross-section through the power-house, and shows the arrangement of generator, turbine, penstock and draft-tube. Fig. 1 is a plan of the power-house, showing the switchboard, the exciter layout, and the general arrangement of the turbines and generator.

The three generators are of 1,250 kv.a. capacity, revolving field, two-bearing, water-wheel type. Two exciters are installed of 40 kw. each, belt-driven. The electric generators and all electrical equipment were supplied by the Canadian Westinghouse Company. This equipment further includes about 2,500 horse-power in induction motors, about 700 horse-power in synchronous motors, a 17-panel switchboard, black marine finish, for the power-house, and a five-panel board for the substation.

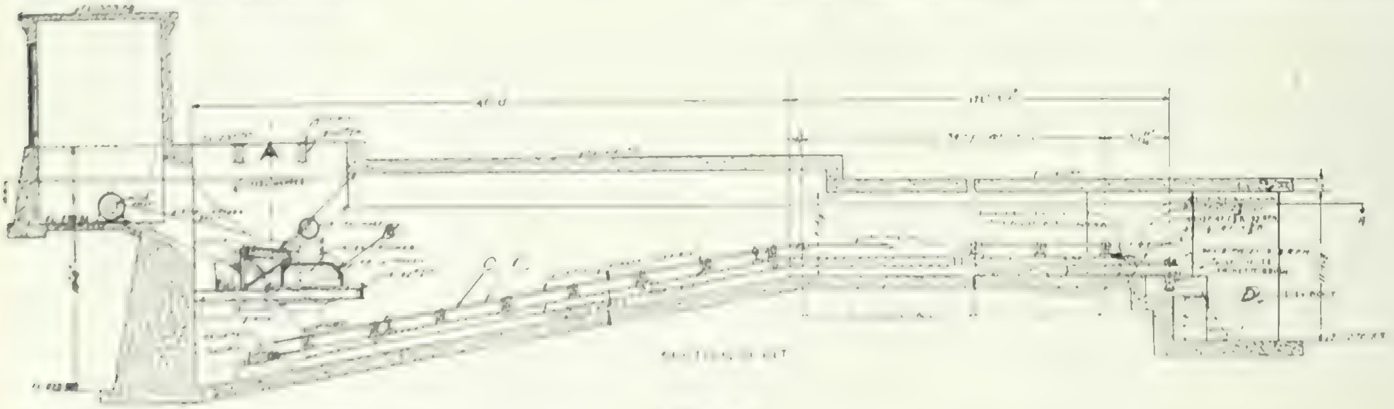

Fig. 3.

The steam plant equipment has also been carefully designed with a view to the most economical handling of the fuel and the labor. The arrangements for handling the fuel were governed largely by the necessity of storing sufficient fuel to meet the requirements of the mill during the winter months. A storage area of ground adjacent to the railway tracks has been taken, and a spur track laid in a manner that will permit piling the coal to a depth of [illegible] as the grade is level. As much area of ground can thus be covered as will ensure a sufficient supply over any desired period of time. For taking coal out of storage and placing it in the furnaces, mechanical handling has been adopted throughout. The coal is first dug from

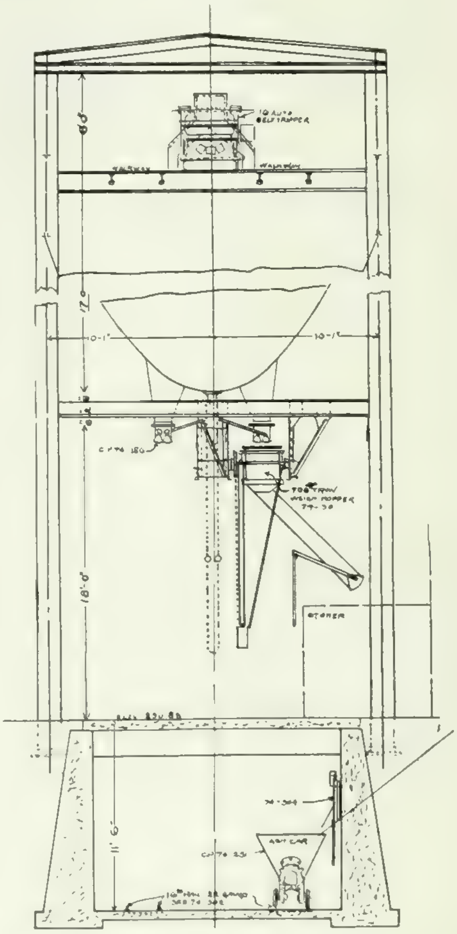

Fig. 4.

the storage pile by means of an orange peel bucket operated from a steam locomotive crane and loaded into a bottom-dumping car. The locomotive crane is then used to shunt this car to a track hopper, into which the car is discharged. Under the track hopper is arranged a crusher and feeding-gate, which feeds the coal to a belt conveyor. This conveyor carries the coal from the track hopper to a point at the end of the boiler house, where it is elevated by means of a bucket elevator to a belt conveyor, which distributes it in a steel coal bunker over the boilers. Here there is capacity for storing approximately one week's supply of coal for the boilers.

The coal bunker is placed at an elevation suitable for drawing coal by gravity to the Murphy stokers attached to the boilers. In its passage from the bunkers to furnaces the coal is weighed and daily records kept of the consumption.

For the handling of ashes a tunnel has been constructed under the boiler-house, into which ashes can be drawn by gravity from ash hoppers under each grate. Industrial cars are used to collect the ashes from each of these ash hoppers and transport them to the end of the tunnel, at which point they are dumped into a skip hoist. The skip hoist consists of a sheet steel bucket, which is raised on an inclined track, dumping its load into a large storage bin for ashes and returning to its position in the tunnel automatically. The storage bin for ashes is supported on a steel tower at a suitable height to permit drawing off into railway cars when a sufficient quantity has accumulated.

The coal is dumped from railway cars into a receiving hopper (Fig. 3) (a), and is fed into the crushers by an automatic feeder, where it is crushed to stoker size (b), and then flows on to a belt conveyer (c), and then conveyed with the same belt conveyer through a tunnel to an elevator (d). From there it is elevated to the top of the steel tower and led on to a belt conveyer, which leads over the coal storage bunkers in the boiler-room. It is distributed into this bunker by an automatic travelling tripper (Fig. 4), The coal is then drawn from the bunkers into one traveling weighing hopper, and is accurately weighed. From there the coal falls into the stokers.

The entire apparatus is automatic from beginning to end, and avoids the use of manual labor for the handling of the coal.

The ashes are dropped from the hoppers underneath the boilers into side-dump ash-cars. These cars are pushed by hand, and are very easily operated, having roller bearings, and are taken out through a skip, at which place the ashes are dumped into the skip hoist into a bunker. This bunker is carried in a steel tower, and from there drawn into the railway cars. In this instance also the entire apparatus is practically automatic, and only requires the attention of one man to touch the button in order to operate the apparatus.

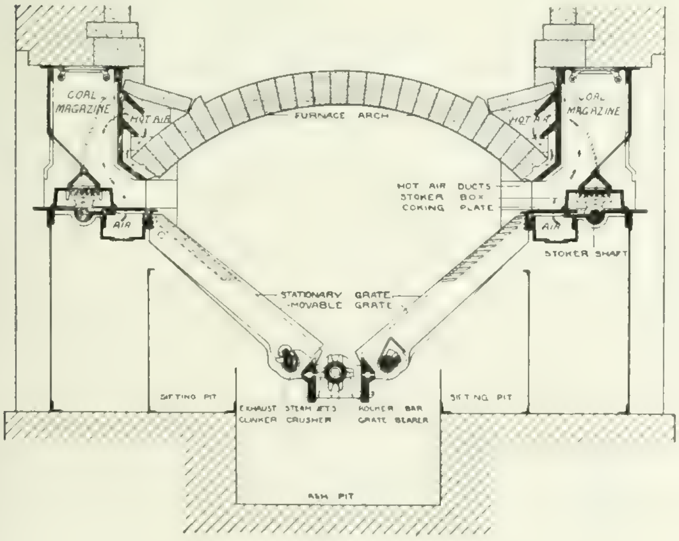

Fig. 5.

Two 600 horse-power steam engines of the Corliss type supply power for running the paper machines, and the exhaust steam from these engines is used for the drying of the paper.

Fig. 5 shows a transfer section through the Murphy stoker. Fig. 6 is a longitudinal section of the same.

Joseph H. Wallace & Company, Temple Court Building, New York, designed the plant. The water-wheels were manufactured by the Holyoke Machine Company, of Worcester, Mass.; the generators and switchboard by the Canadian Westinghouse Company, Hamilton, Ont.; the boilers by the Robb Engineering Company, of Amherst, N.S.; the steam engines by the Goldie-McCullough Company, of Galt, Ont.; the economiser by the B. F. Sturtevant Company, of Hyde Park, Mass.; the steam piping by M. W. Kellogg Company, of New York. The entire coal and ash-handling equipment was installed by the Exeter Machine Works, of Pittston, Pa., while the Murphy Iron Works, Detroit, Mich., furnished the Murphy automatic, smokeless furnace. The penstocks were built by the Jenks Machine Company, of St. Catharines, and the hydraulic governors are of the Lombard type.

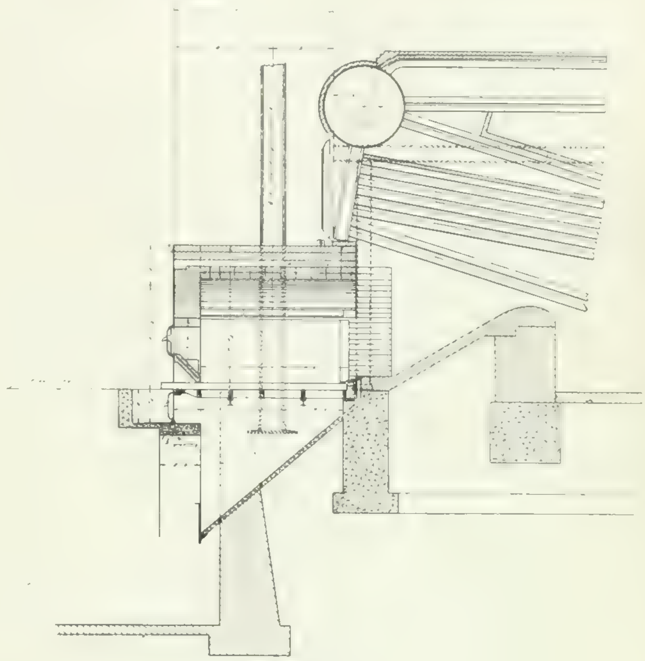

Fig. 6.

FIRE TESTS WITH GLASS.

From the conclusions of the recent fire test with glass of the British Fire Prevention Committee, the following excerpts are taken:

Too little account is often taken of the effect of an external fire on a fire-resisting building, and the protection of the vertical enclosure seems to be more often than not forgotten or neglected.

We have in fire-resisting glazing, if properly applied, a very valuable ally, and the report of the tests shows that such a material will afford a most useful amount of protection from the exposure risk.

It would seem that the maximum protection is afforded by fixing the glazing into metal frames or into masonry direct.

It seems regrettable that often the value of such a useful article as the type of glazing may be seriously discounted by inefficient fixing. It thus behoves the officers of the local authorities concerned to be on their guard in this respect.

A WATER SURVEY OF OTTAWA.

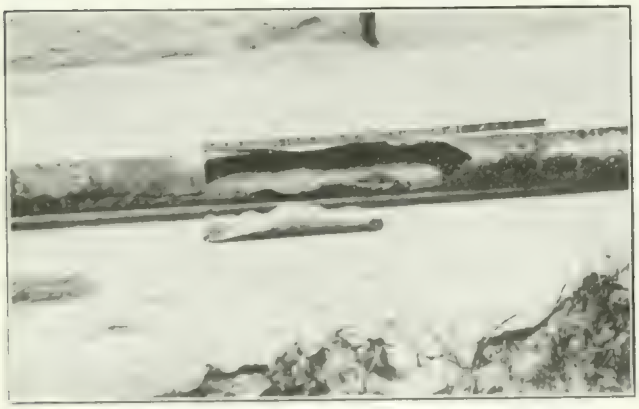
Some months ago we noted in *The Canadian Engineer* that the Pitometer Company, 220 Broadway, New York, were starting work on a pitometer survey of the water mains of Ottawa. Some results have been secured by the company, and through the courtesy of Mr. E. R. Howland, the resident engineer in charge of the work for the Pitometer Company, we present them herewith.

Work was started on May 22nd at the pumping station, and all the pumps were tested for slip. The following tabulation shows the results secured. The results show that, with few exceptions, the pumps were in remarkably good condition.

All the pumps are horizontal, crank and flywheel, and have outside packed plungers.

Results of Tests on Pumps.

Pumps, No.	Type.	Discharge per revolution in gallons per 24 hours. Theoretical.	As measured by pitometer.	Per cent. of slip.
	Triple	127.0	127.0	[illegible]
2	Triple	127.1	126.8	0.0
3	Triple	127.72	118.5	7.2
4	Triple	342.42	[illegible]	11.5
5	Duplex	10[illegible].25	97.6	5.[illegible]
6	Duplex	1[illegible].25	102.5	0.7
7	Duplex	[illegible]	105	1.0
8	Duplex	[illegible]	101.4	4.4



View of Three-Inch Broken Main to Foundry.

[illegible] survey of the distribution system was started in the first [illegible]

[illegible]

Three-inch service to disused foundry badly [illegible]

[illegible] main blanked on both sides of the water.... 350,000

A number of leaks have also been found on abandoned and fire services, bringing the total leakage, discovered to date, and repaired, up to about four million gallons per day. Many of the mains in Ottawa are laid in rock cut; the waste water, therefore, easily finds its way into the sewers without giving any surface indication. It is stated that some of the leakage discovered was undoubtedly caused by the exceptional depth reached by the frost last winter.

The illustration shows the break in the three-inch service to the foundry, mentioned in the above description of leaks.

◆

EFFICIENCY IN EDUCATION.*

By Dr. George A. Hoadley.

We are living at a time in which the question of securing the highest efficiency in every form of business enterprise has become a dominant one. No man would undertake a business unless he could assure himself at the very outset that every department of it could be conducted both economically and efficiently.

For a man to take such precautions is not only an evidence of good common sense, but the stand is one that must be taken as a matter of self-protection.

There have been times in the progress of almost any kind of business when it was possible to keep it alive, and even prosperous, in spite of the careless and wasteful methods employed; but at the present time, when our excellent systems of communication have brought all parts of our country together and when manufactured products can be quickly delivered to the places where they are needed, however remote any manufacturer is almost as keen a competitor of another a thousand miles away is though they both lived in the same city.

Space and time have been annihilated, from the business standpoint, and the man who does not meet the standards of economy and efficiency set up by his competitors will be crowded off the course by their inertia of motion or left stranded far in the rear by his own inertia of rest.

Since there is such a demand for high efficiency in the business world, it may be well for us to enquire whether there can be efficiency in education, and, if so, how it may be secured.

At the very beginning we are met with fundamental differences in the conditions. In the factory one has to do with inert matter; in the school, with individuals whose actions are governed by their own wills. In the factory we deal with a piece of automatic machinery which does the thing for which it was made, or, if it does not and refuses to work at all, it is largely our own fault in allowing it to get out of repair and become useless. In the school we deal with separate personalities, no two of which are alike, and no two of which are sure to do the same thing under exactly the same conditions; while, if the results obtained are not what we want, we are limited to the giving of advice, which is accepted or not, according to the mood or fancy of the one who receives it.

It would seem, then, by this comparison of the material with which we have to deal, that the problem becomes a much more difficult one when we bring it into the field of education.

When a man designs a piece of automatic machinery he must, in order to be at all successful, have very definitely in mind the purpose for which the machine is being designed: what it is that the machine is to do. To take any other course would stamp the attempt with failure from the start.

---

* Address delivered at the meeting of the Alumni Association of the Franklin Institute, March 23rd, 1912.

To secure efficiency in education, should there not be the same clear-cut, definite knowledge of the result to be obtained? There is in both cases a groundwork of that which is fundamental. In the case of the designer it is his knowledge of the physical qualities of the materials to be used. He must know what the limit of elasticity is of the material that he proposes to use in every part. He must know whether it will be able to stand the strains that will be put upon it in the work that it has to do. He must know whether there is a choice in this material, and he must make choice of the very best, or the next man who takes up the problem and who can profit by what he has done will so far surpass him in his design that the work will be a failure through the very competition that it invited, by not being the best machine that could be made. Not only must the designer have this fundamental information, but this fundamental strength, this fundamental elasticity, this fundamental adaptability must have been put into the material by the maker, or the machine will be a failure through his lack of this fundamental knowledge.

The same thing obtains in efficient education. There are, first of all, the fundamentals to be obtained and to be made such a part of the every-day life of a child that they seem to him things that have always been known.

At the very foundation of these fundamentals I would place the ability to think straight. Perhaps you think that I am beginning at the wrong end, and that the ability to think straight is the aim and end of education and cannot be had at its beginning. Well, there may be some reasons for your opinion, but I really believe that in order to secure efficiency in education it must be founded upon the ability to think straight, to have the moral sense of what is right and what is wrong; and, moreover, I believe that this ability is common to most men and women.

To the man who does not think straight, or who will not, an education brings at most the ability to succeed in things in which it would be better if he should fail. There is another phase of thinking straight, and that is to have one's thoughts clear and well defined. This, too, seems to me to be one of the fundamentals in education.

If we are to have any hope whatever of being of service to those about us, or of being influential among them, we must be able to present our opinions to them in a clear and forceful manner, and this we cannot do unless we are able to think them out clearly to ourselves. It is a pleasure to listen to a man who has a definite purpose in his mind, and also has the ability to express that purpose in fitting words, and so I would include, as another fundamentally important thing, an ability to use one's native tongue forcefully.

Too frequently, none of the things that I have mentioned are considered as a necessary part of an education at all. In addition to the ability to understand and use the English language, there is one other department of knowledge that lies at the very foundation of daily life, and that is mathematics. Now, do not think of the kind of mathematics that delights the mathematician, for what I mean is the fundamentals—that is, the elementary mathematics, such as arithmetic, algebra, and geometry. If we consider for a moment that the great discoveries of Nature were most of them made with just these branches of mathematics applied to the questions in hand, possibly adding trigonometry for the use of the astronomer, we shall see that the essentials are elementary.

No one can live in our times, surrounded as we are by the most striking applications of science, without feeling that a study of the natural sciences is required in order to consider that we may be entitled to the name of educated people. Here, again, the fundamentals are of the greatest importance. Take, for example, electricity, which has so general an application in lighting, heating, and furnishing us a means of transportation. As a matter of fact, the essentials are few. It is in the applications that there is so great a divergence. Let a man be thoroughly grounded in the elementary principles of magnetism and electricity: it is a simple matter of diligent application of these principles that solves the most intricate problems to be met.

When we calculate the efficiency of an electric generator, for example, we find that it is the ratio of the power output to the power output plus the **losses.** How are these losses made up? Why, there is the loss in the shunt field, and this we expect and are willing to allow, because if there were no shunt field there would be no lines of magnetic force for the armature wires to cut, and there would be no voltage generated for delivery at the brushes. Then there is the armature loss, and this we expect, for there must be wires to cut the lines of force, and they all have some resistance; hence there is a heat loss in the armature that increases as the current increases. Then there are the stray losses—those heart-breaking losses that the designer tries to cut down, and generally fails: losses that have no compensation; that have no redeeming feature; that are only detrimental to the machine, and that cut down its efficiency ten per cent. How are these losses made up? Why, there is the friction between the shaft and bearings, between the brushes and commutator, between the rotating armature and the air. There is the time-lag or hysteresis loss, and there is the eddy current loss, which is due to currents set up by the cutting of the magnetic lines by the armature core or the pole pieces, and which only serve to heat up the machine and increase its resistance. Now, how does this apply to education? What I would say is that if we wish to increase efficiency in education we must cut down the losses. Perhaps there are some of them that are really so connected with the system or method that they cannot be avoided. But there are certain others—the stray losses—that are wholly harmful, and these should be eliminated. The friction losses between teacher and taught should disappear. The system should be so changed that friction between both teacher and taught and the system should not be possible. And greatest of all, the eddy currents, those vampires that destroy uselessly, caused by inattention, lack of interest, lack of enthusiasm should be themselves destroyed.

To ensure efficiency in education there must be a greater saving in another great loss, and that is in the loss of time. This requires that one shall know without question what it is that he wants to inform himself on, and not flounder along helplessly for months or years with no definite goal in view. You who have the opportunity of taking the courses that the Franklin Institute offers have had the advantage of knowing definitely what it was you wanted to study. You have had the opportunity placed before you of applying yourself directly to the problem in hand, and if you have taken advantage of these opportunities you have the consciousness that the education so secured has brought with it something that has been of real and lasting value. I believe we should never look upon our education as a thing of the past. I greatly admire the point of view of the centenarian who had completed his hundredth year in this year 1912 who went to a shoemaker to have a pair of shoes repaired, and who was very insistent that they should be made strong enough to last a long time. The shoemaker said to him: "Why, you are a hundred years old, and still you seem to be as anxious that these shoes shall last as though you were to live another hundred years." "Well," said the old man, "perhaps I shall. I am a great deal stronger than I was when I started out in 1812." That is the kind of optimism that I like.

3000 KW. VERTICAL ROTARY CONVERTERS.

Two 3000 kilowatt, vertical, synchronous booster, commutating-pole, rotary converters have just been built and tested by the Westinghouse Electric and Manufacturing Company in its East Pittsburg works. These two machines, which are of unusual interest because they are the largest vertical rotary converters ever constructed and because they are the only vertical converters ever built involving the synchronous booster and commutating-pole features, are for the New York Edison Company for installation respectively in its Clinton and its Crosby Street sub-stations.

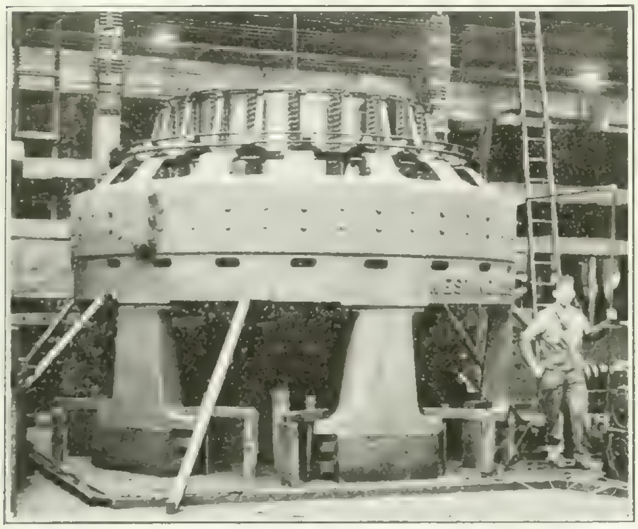


Fig. 1. 3000 kw., Vertical, Synchronous Booster, Commutating-Pole, Rotary Converter on Test.

The converters deliver a normal direct current voltage of 270, and are for 25 cycle, 6-phase operation. The direct current voltage variation obtained by virtue of the booster feature is 15% buck and 15% boost from the normal voltage, giving a total direct current voltage variation of 30%. These machines were made of the vertical type to conform in general construction to the other converters in the sub-stations, all of which are vertical machines.

Fig. 2, a sectional drawing, shows the detail construction of the machines. The converter armature and frame are mounted above the booster armature and frame. The commutator is at the top of the machine and the collector rings at the bottom. The armature consists of a rotary converter of the usual [illegible] mounted on the same shaft with the smaller booster armature, which is connected in series with the converter armature so that when the booster field excitation is varied, the alternating current voltage impressed on the converter armature will be decreased or increased accordingly.

The main or converter poles are shunt wound. The commutating poles which lie between the main poles have been [illegible]

to the armature coils, and through these spaces the cooling air is forced by the rotation of the machines. A commutating pole converter which is to be started from the alternating current end must be provided with a brush lifting device, but inasmuch as these machines are to be started from the direct current end, a brush lifting arrangement is not necessary.

Some of the mechanical constructional features are unique and different from any heretofore used for vertical electrical machines. The pedestal on which the armature rotates, and which is plainly shown in Fig. 2, is a one piece, hollow steel casting having a large area of base. With this construction a much more rigid structure results than with the usual one wherein a steel pedestal with flange on its lower end is bolted to a cast iron base. The pedestal is tapered so that the upper bearing is smaller in diameter than the lower one. This facilitates assembly. The bearings proper are babbitted and cast in a sleeve which can be readily taken out of the converter spider for re-babbitting.

A roller thrust bearing is arranged at the top of the pedestal to take the weight of the revolving element. The bearing rests on a plate which has a spherical seat carried on the pedestal so that perfect alignment is assured. The roller bearing can be taken out by removing the top plate of the machine. To assume the weight of the rotating part at times when it is necessary to remove the top plate, six 1¾ inch bolts are provided that turn through the lower portion of the pedestal flange. When it is necessary to take off the top plate, these bolts are screwed up until they raise the rotating element a trifle and assume its weight.

Lubrication is effected with a gravity oiling system. The oil is drawn from the reservoirs and forced up through the oil pipe in the centre of the pedestal. At the top of the pedestal, the oil discharges through a nozzle into a cylindrical chamber within the roller bearing. The pressure on the oil forces it from this chamber out between the bearing rollers into an annular pan surrounding the roller bearing. Oil cannot leave the chamber except through the bearing, and the height of the outlet nozzle and the oil pan rim are such that the bearing rollers always travel in a bath of oil. When the oil overflows from the pan around the roller bearing it passes into an annular chamber just above the upper pedestal bearing. From this chamber its only exit is through oil grooves in the pedestal. While it is passing through these grooves the rotating babbitt bearing surfaces take up oil. From the upper pedestal bearing the oil flows down through the chamber around the shaft to oil grooves for the lower bearing similar to those above described. From the lower

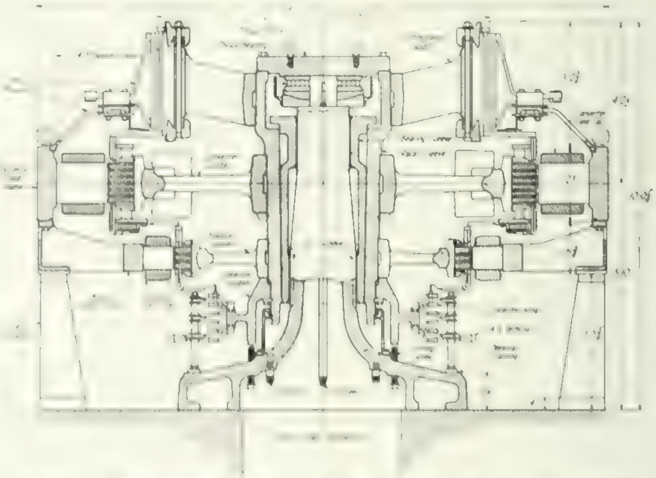

Fig. 2. Sectional View of 3000 kw. Vertical Converter.

oil grooves, the oil discharges into an annular reservoir to the lower part of the pedestal from which it drains into a storage reservoir to be circulated again through the lubricating system. An effective oil thrower arrangement is provided at the upper part of the oil space and around the lower part of the pedestal which effectively prevents oil creepage up the shaft.

◆

EFFECT OF INSTALLING METERS AT DECATUR.*

By Harry Ruthrauff.†

As to the effect of installing water meters at Decatur, Illinois.—First let me say I do not wish to claim the title of an expert; but simply wish to state the facts as I have found them during my twenty-two years experience in the water department at Decatur.

I believe it important for every community to obtain and conserve, without unnecessary waste, a water supply ample and suitable for all purposes. The question with me from the beginning of my experience was,—"How to Stop Unnecessary Waste?"

I was first employed as a laborer in this department; later as foreman and finally in the year 1894 was appointed water inspector. I therefore knew of the great waste of water upon entering the duties of my office.

The first five years I served as water inspector I worked faithfully in an effort to stop the waste, which was enormous, due to carelessness on the part of consumers and defective plumbing. I used every honorable means along this line, always looking after this work personally. In 1896 I employed four assistants with the avowed intention of stopping all leaks, and thereby preventing waste in the city. I again went over the city in 1898 with four assistants, looking after this waste, giving the matter personal attention.

I brought into our police courts citizens by the score and prosecuted them for wilful waste. After about five years labor along this line, I began to get discouraged. I found that a great many of our citizens believed we had an inexhaustible supply of water, therefore could not see any good reason why I should be so extremely anxious about this matter. Consequently, I began to look for some other plan. I believed, if this waste were allowed to continue, taking into consideration our rapid increase in population, we would in a short time find our supply short, or be at an unnecessary expense for additional machinery, mains and enlargement of our reservoir and filter plant to handle water merely to be wasted.

In 1901 I recommended to the council the adoption of the water meter on all services. The recommendation was filed, but no action taken. Again in 1902 I urgently recommended the same plan and was then ordered to have all the livery stables, hotels and laundries install meters. I was then able, by comparison, to prove the water meter would be beneficial both to the city and the consumer, and each year thereafter I strongly recommended the placing of all meters on all services, and finally in the spring of 1908, the council ordered all services metered by July 1st, 1908. The results are as follows:

April 31st, 1904, the end of our fiscal year, we had 2,112 services recorded; five consumers for each service gave us 10,560 consumers; 987 of these services were metered. I wish to say here that there was no record kept of the water pumped prior to the year 1903. However, with 10,560 consumers, 4,935 of them metered, there was pumped for this year 1,023,463,180 gallons, which gave us a per capita consumption of 266 galions.

Revenue for this year was		$32,812.99
The operating expenses at plant for this year were	$17,100.84	
The operating expenses, outside of plant, such as laying mains, repairs, etc., were	5,899.16	
The total expense		23,000.00
Leaving a balance of		$ 9,812.99

The plant was operated at this time with two shifts with coal costing $1.50 per ton.

For the fiscal year ending April 31st, 1911, we had 4,939 services in use, 4,933 being metered. I will say the 6 services unmetered are large consumers. This gives us, on a basis of 5 consumers to the service, 24,695 consumers. There was pumped during this year 1,124,212,338 gallons, which is 100,749,158 gallons in excess of that for the year ending April 31st, 1904. With an addition of 14,135 consumers, we now have a per capita consumption of less than 125 gallons. It is my belief that if the six consumers previously mentioned were metered, our per capita consumption would be less than 100 gallons. This may yet seem excessive to some, but we have some very large consumers for a city of our size, having 6 consumers using annually about 300,000 000 gallons.

The operating expenses at the plant for the year ending April 31st, 1911, were	$30,657.23
The operating expenses outside of plant, laying mains and miscellaneous were	26,960.01
Making the total expense	$57,617.24
The revenues for this period were	52,577.00
Leaving a deficiency of	$ 5,040.24

We now have three shifts at the pumping station, with coal costing us $2.15 per ton. The lowering of the water rates a few years ago and increased cost of operation are the causes of the deficiency, which has been overcome by a slight raise in water rates effective July last.

We have accomplished by the enforced use of meters at least a 30 per cent. reduction in the average householder's bill. Under the old flat rate system a 7 room modern house would cost him $17.00 per year and under our present system, his yearly bill should not exceed $12.00.

We have also cut the per capita consumption from 265 gallons to 125 gallons,—thereby saving, at the present time, an unnecessary pumpage of 1,270,928,175 gallons each year. Therefore, the benefit derived from a complete metering of any city is very clear to me.

◆

General passenger agent W. P. Hinton, of the Grand Trunk Pacific Railway, says that such good progress is being made with the construction work that the line will be completed from Winnipeg to Prince Rupert by the end of 1914. There is at present a gap of 300 miles between the western end of the line in Yellowhead Pass and the eastern end of the completed line from Prince Arthur. Mr. Hinton says the Grand Trunk Pacific will do its share in the movement of this season's grain crops. He estimates that the Western farmers should have $75,000,000 more to spend from this year's crop than they had from the yield last year.

---

*Paper delivered before Illinois Water Supply Association, March 5, 1912.

†Commissioner of Public Property, Decatur.

MAINTENANCE OF ROADS AND PAVEMENTS.*

By James Owen.†

The writer of this article would have preferred that the title of this paper should have been the economies of roads and pavements, as he sees that at this stage of road development the financial question is paramount. But as finally the maintenance problem is the one with which to deal, the discussion of that feature will of necessity include the money end, so it is hoped that undue stress upon what is sometimes too apt to be ignored in engineering in the means of construction as well as the methods will be pardoned.

In discussing the pavement problem in such an extensive country as this, with its varying climate, topography, materials to be used and habits of the people, it would seem impossible for any one individual to cover the whole ground, as, of necessity, each man's environment and experience are limited. Yet, the aggregate of such experience will be of value to all. So, if in these remarks statements at variance with the ideas and experience of other members of this convention are made it is hoped that prompt repudiations of the statements will be evolved, as by such means will accurate data be accumulated.

To properly consider the subject in its entirety it may be wise to indulge in a classification of the people, the pavements and the pay. The traveling people may be divided into urban, suburban and rural and it may be confidently stated that the requirements of the pavements differ in character practically in accordance with this division, except that there may be a certain overlapping due to special conditions. This covers two heads. The ability to pay varies spasmodically with climate, topography and the energy of the community.

Now enters into consideration the character of vehicles which there are to-day two, self-propelled and horse-driven. Both of these may be divided into fast and slow moving, the heavy wagon, the light buggy, the motor truck and the automobile, these introducing still other items, the iron tire of the wagon, the solid rubber of the buggy, the corrugated tire of the motor truck and the pneumatic tire of the automobile. All these factors vary in weight and speed and their effect on the surface of the pavement is of vital importance.

[illegible], is the effect of different pavements on the tires of vehicles. So far, the owners of such vehicles have been so busy trying to get something smooth to ride upon that they have been content to pay [illegible] ungrudgingly, yet in the future it will be an important economic factor.

[illegible] to-day is the most important in road construction, viz., the suppression of dust. Also, there enters in, to a lesser degree, the suppression of [illegible]

[illegible]

and with proper care in the selection and manufacture of material and a conscientious disposal of it in place, and in most cases a smooth dustless pavement will be secured. But here enters the question of maintenance and also the traveling factor. At the same time there arises a controversy between drivers of horse and motor vehicles on the question of smooth pavements, the horsemen claiming that the smooth pavements, like wood block or asphalt, are impassable and useless at certain periods for heavy hauling and should not be tolerated. That at seasons their slipperiness is detrimental is not doubted. However, this point is one for purely local consideration and cannot be generalized upon.

Cobbled and old-fashioned granite block are certainly permanent but not desirable. The close jointed grouted granite block and the Medina sandstone would seem to be ideal. They are smooth, and once down relieve the maintenance department from attention for a generation. Wood block as now laid is desirable, smooth, and, at times, slippery, but its permanency is unknown.

The brick pavements of to-day are desirable and appropriate, especially in districts where there are no stores. Here it is proper to make the statement that many paving brick manufacturers are setting an example to the community in concentrating their efforts on making and delivering the best possible brick, relying more on the character of the material than on their profits for future prosperity. The writer suggests this example to other industries. Brick pavements as now constructed also relieve the maintenance department, if proper care is used in discriminating on certain character of travel. Where there are extraordinarily heavy loads and dense vehicular travel, it is not wise to use brick.

We now come to the mastic propositions in which the maintenance department sooner or later takes an interest. The asphalt and tar preparations give a smooth, dustless and serviceable road, and are desirable for residential sections and in many cities are universal. Their maintenance is carried on in different municipalities in different ways, some owning their own repairing plant, others contracting the repairs, and still others neglecting them altogether. It is safe to say, however, that after five years' use of these pavements the item of repairs begins to be a factor, although the writer has one asphalt pavement which has been in use for nearly ten years without repairs or apparent necessity for them.

Interjected into many cities is the use of cheaper pavements for purely residential streets of both high and humble character. Sanitary precautions in some cases cause their existence before the demand is made by the residents who often are not able or willing to pay. In other instances they are laid at the desire of the property owners, and in these the maintenance problem soon appears, and the practice there can be considered the same as in suburban communities.

In street development in suburban communities or small towns there are new factors to be considered. Except in main thoroughfares the travel is light. The unwillingness to pay large assessments and also the suppressing of dust has opened the field to endless inventions with varying materials to provide cheap, smooth and dustless pavements. All kinds of pavements have been promoted and enormous sums of money have been expended in experiments, and it is to be hoped that in the near future a practice may be adopted available to all within their means. This same idea extends, to a degree, to rural highways, and it would seem desirable to discuss the problem as common to both classes of communities.

---

*[illegible] American Road Builders' [illegible]

†[illegible]

To properly appreciate conditions it would be well now to consider what these pavements, so-called, have to endure. With horse-drawn vehicles and steel tires, the roads were constructed to be available for such use and the standard generally adopted where material was convenient was the macadam or telford pavement, using the local rock if possible, but in many cases bringing it from 200 to 250 miles by water or rail. Where rock was not available, other natural materials were used, such as gravel, shale, chert, sand and clay, and in the arid sections, clay and oil. The success of these pavements when properly constructed and maintained gave an enormous impulse to automibile travel, in some cases causing it to supersede horse travel. The rapid increase of automobile travel, however, speedily began to impair the surface of the highways and pavements, and also created volumes of dust. This condition started new ideas and new investigations, of which we are now in the throes.

Careful comparison of the effect of iron tires and shoes and rubber tires on road surfaces shows a marked difference in their action. Under the old order of things, if a coating of broken stone or gravel were placed on a highway it was confidently expected that the surface would soon be consolidated. It was probably wearing out the patience of the traveler, but showing that a consolidatory effect was obtained. The writer has made experiments with automobiles, at low and high speeds, both on macadam and gravel surfaces and finds that their action is disturbing, the higher speed the greater the disturbance created. There are, therefore, two opposing factors in the maintenance of present highways and the resultant is determined by the preponderance of certain kinds of travel. Where the wagon travel is universal the old conditions exist and the old practice may prevail, and where the automobile is universal, an entirely different system of maintenance has to be followed. But where there are equal volumes of the two kinds of traffic the greatest difficulty exists. The question of the future must now be considered. Will automobile travel entirely supersede wagon travel or will the travel still be mixed? It is well accepted that there is a great growth of automobile use and a great diminution of horse-drawn vehicles and the decision of such a factor is purely local.

Another very important factor is the suppression of dust, and here the writer wishes to enunciate the fact that the automobiles themselves are not the creators of the dust, as is generally considered. The steel tire with its grinding action creates the dust and the automobile, with the wind, disturbs and scatters it. As a proof of this a coating of screenings laid in late spring on a road carrying only automobile travel will still be in the same condition in the fall, merely disturbed, but not consolidated. And there will be no dust.

Taking these facts as axiomatic, the maintenance of all pavement surfaces liable to wear must be considered as a purely local problem governed entirely by the local travel. The dust question has this peculiarity: It may be more troublesome on a less traveled highway. This question, while of somewhat recent origin—that is to say, while there was always plenty of dust, the public for some occult reason did not complain of it—is really the governing source of all new efforts at road making, and is just as much of an economic problem in rural communities as it is in urban. The impairment of the value of crops, especially fruit, is an accepted fact and the demands for suppression are insistent and imperative. In the effort at dust palliation a large amount of gray matter has been expended and a great many expedients have been devised. Setting aside the experience of the French engineers at Algeria where the first experiments in dust suppression were made with the oil of Massat, the California practice was really the first that did not use water. But we all understand that water was the first material used for dust suppression, whether by rain or the watering cart. In southern California there is little or no rain and the heavy mineral oil was used, first by surfacing the adobe soil with clay and then sprinkling the oil. This gave good results and an application twice a year proved satisfactory.

This idea spread and the practice of using crude oil for surfacing came into vogue. The smell in the houses and the ruination of carpets and clothes stopped its use and then oil, without the smell, was manufactured, and with some of the stickiness eliminated. These oils, generally with asphaltic bases, gave general satisfaction and are now in general use. The idea, however, was prevalent that a dustless, smooth, permanent surface could be devised that would be cheap and effective, and such surfaces have been provided, but the question of cost then becomes the vital point.

The original experiments made by Mr. Blanchard of Rhode Island in resurfacing roads with asphalt or tar mixtures and the reasonable low cost with good results after a limited period of use encourage the whole country, as well as the writer to be up-to-date and do likewise. It must be understood that those experiments were made by a competent engineer with selected help. When, as is often the case, communities do not employ a competent engineer nor have selected help, however, very different conditions prevail.

The writer started on the unknown path and resurfaced miles of road with heavy asphalt oils by the penetration method, and also drew specifications for new roads to be built by the same methods. The results, however, were so unsatisfactory that the practice both in old and new work was quickly abandoned. Subsequently contracts were made for work by the mixing method both by cold and hot application and results from them have been satisfactory. The final practice arrived at by the writer is to build his roads by the old water bound method and then apply a light surfacing oil at the proper season to allay the dust. This is found to give the smoothest pavement for the least money on an average country road in New Jersey where there is a large automobile travel.

The experiences in the penetration method were peculiar and there was also a curious case from the fact that the engineer was compelled to rely upon the chemist for his data, accepting such data even though based on meager procedure. The question of manipulation by the labor available became more of a factor than the chemical data. Men of experience in the old practice were at sea in the new methods, and in one case, even though an expert was called in and special men were employed, the result was unsatisfactory, from an engineering standpoint. It is true a certain percentage showed good results, but forty per cent. efficiency is not ideal.

In one instance a section of newly built road a mile in length was finished in the fall and presented a good, smooth surface. In the spring, however, the surface broke to pieces over the entire length and had to be renewed. In other cases the rolling of the surface mixture into waves practically put an embargo on travel and the surface had to be entirely removed. In another case a rut six inches deep and a half a mile long appeared with no apparent cause. With such experience the writer may be excused from indulging in any more surfacing escapades.

With the mixing process better results have been obtained. In one case, with a hot mixture, the surface, after being rolled and having cooled, was a series of waves

Curiously enough, after eighteen months of travel these waves disappeared and a smooth surface now exists with no appearance of wear.

The cold mixture gives excellent results, producing a surface that is smooth and equal to asphalt.

A few experiences in surface oiling may be interesting. In maintaining a system of 150 miles of road with city and suburban travel a complete system of repairs is obligatory and breaking the continuity of such a system leads to complications. As the demand in the writer's section for the suppression of dust was in the spring it was considered desirable to find an oil that would last the season. It did last the season in most local cities, but such an oil ruins the surface of a pavement, creating a pitting which is very objectionable. This heavy oil of course prevents the ground particles of the road from being blown away but when it rains an emulsion is formed which is of great local objection. Therefore it was found advisable to use a lighter oil with more frequent applications, and with such practice no impairment of the surface is presented. With the practice of repeated applications of dust preventives the use of materials not containing oil may be advisable, depending of course on the system in vogue and the cost of the material itself. Some of these the writer has tried but so far not with the success anticipated. In residential localities these preparations are of advantage as no oily particles of dust are carried into the houses or on the clothes of wayfarers.

There is one other point that the writer wishes to emphasize, and that is that with the growth of automobile travel the character of the mineral aggregate in any mixture is of secondary importance. Under the old conditions, hard trap rock was ideal and was used wherever available, even when long hauls were necessary. Such an insistence is not now necessary as it is found that with the grinding eliminated and the use of surface oils, good gravel gives as excellent results as the trap rock. Granite can be used with impunity, and such natural materials as chert and shale can also be used. The sand and clay roads of North Carolina can, with oiling, be made into perfect roads, as is shown in California. A full appreciation of such a fact will reduce the cost of thousands of miles of roads in the future.

The writer now wishes to allude to the financial problem in road construction, and it might be well to note the varying channels from which money comes. Taking my own State as an example, these are as follows:

City street paving.—A part, say about 80 per cent., on property, balance on the city at large. Maintenance a city charge.

[illegible]

[illegible]

[illegible]

[illegible]

[illegible]

As to ability, that is a condition hard to gainsay. As to willingness, that can be overcome by education. To properly educate a community to higher ideals and standards, those ideals and standards must first be crystallized on a permanent basis and then set before them.

In too many cities of the United States there are rough and unsightly pavements tolerated by educated people and traveled over with repugnance, yet there they are. In country districts where good roads have been made they have been allowed practically to disappear through neglect. In other communities the desire for the ideal and also the willingness to pay are both present yet the supply of talent and material is deficient.

So, in this question of road surface maintenance the practice in cities is fairly conceded to be beyond controversy. Only the money is required.

In suburban and rural highways this problem confronts us: ·In days before the automobile, with wagon travel alone and with a system of roads in cities, towns and country, the average cost of macadam repairs was three cents per square yard per annum. This, by increased travel, increased cost, and automobile, has now raised the cost to six cents, and the oil at one cent brings it up to seven cents per square yard per annum for having and keeping a smooth oil surface.

Rejecting the penetration method as erratic and uncertain and applying the mixing process the cost runs from 80 cents to $1.10 per square yard. Consequently the mixture has to last ten or twelve years to be equal in actual cost to the oiled macadam. Another item enters in. The renewal by mixing, or 150 miles of road 16 ft. wide at, say, 90 cents, would cost $8,300 per mile or a total of about $1,245,000. As this would have to come out of the annual appropriation, whatever money was expended in the mixing should be made a separate item, otherwise the maintenance account of the balance of the roads would show a shortage and deterioration would ensue. This has been the experience of many communities and great dissatisfaction has been the outcome.

In conclusion the writer hopes that in the near future the mistakes and experiences of different men in different sections may bring the practice of road repairs into some definite shape, both as to construction and financing. The community, including the road wearers and taxpayers, want good roads at the lowest cost and are willing in most cases to furnish the money if good results can be obtained. It is the province of this association to supply the demand.

MANUFACTURES IN CANADA.

The census of manufactures of Canada taken last year for the calendar year 1910 as now compiled by the Census and Statistics Office, gives the following comparative statistics, compared with those of the census of 1901 for the calendar year 1900, viz.:

—	1910	1900	Increase	Increase p.c.
Establishments	19,20[illegible]	14,650	4,55[illegible]	31.07
Capital	$1,245,018,881	$446,916,487	$798,102,394	178.58
Employees	511,844	339,173	172,671	50.91
Salaries and wages	$240,[illegible]	$113,249,350	$127,[illegible]	112.[illegible]
Materials	$[illegible]	$266,[illegible]	$[illegible]	125.1[illegible]
Products	$1,164,695,0[illegible]	$481,053,375	$683,641,657	142.11

The capital employed in manufactures increased during the decade by 178.58 per cent. and the value of products by 142.11 per cent. The number of establishments employing five hands and over last year was [illegible], being an increase of [illegible] in the decade.

EMERGENCY WELDING OF BROKEN PARTS OF DREDGES.*

By S. E. Lawrence.

The continuous operation of dredging plants, day and night, and the extreme usage that some of the machinery is subjected to are conducive to many break-downs, which are very expensive both in repair cost and more especially in delays and crew costs while parts are being repaired.

Such accidents are provided against as far as they can be ordinarily foreseen by keeping on hand such duplicate parts as may be expected to give way under usual conditions, and each plant in this district is equipped with a small machine and blacksmith shop to handle emergency repairs. Such precautions do not, however, provide for the larger breaks and the extraordinary accidents, and it is in this particular field that the Thermit welding process has been of service in several instances.

The first time this method was employed by this office was in the repair of the low-pressure connecting rod of the 550-h.p. triple-expansion engine directly connected to the dredging pump on the 20-in. U.S. pipe-line dredge "Col. A. M. Miller."

This fracture was an example of the sudden development of an invisible flaw made in the original forging of the part. This engine had been in constant operation for several years and no precaution had been thought necessary to keep an extra rod on hand.

As it would delay the dredge for an indefinite time to secure a new part from the factory, and also several days at least to machine one in a local shop, it was determined to try and reweld the broken fork. Only fair results were obtained, and it was not thought advisable to use the rod. Then it was that the Thermit process was resorted to. About 1 in. of metal was removed and the parts fastened to a bedplate in as perfect alignment as possible. The weld came out of the sand in good condition and, after removing gate and riser, the part was placed in the engine without further machining and was so used with best of results.

The second instance in which this method of repair was made use of was in the repair of one of the propeller shafts of the seagoing hopper dredge "Galveston." This was hardly a weld in the common acceptance of the term, as there was no uniting of several parts, but it served as an illustration of the varied uses that this method can be put to.

While at work at the mouth of Galveston Harbor a wire cable became entangled about one of the shafts in such a way as to wear a groove in it about 1¼ in. deep and 4 in. wide. This weakening of the 10-in. shaft necessitated its removal, a spare part being substituted. The local shops did not afford a lathe of sufficient size to handle the removed shaft, and other methods of repair other than the conventional ones had to be resorted to.

Two processes suggested themselves, the oxy-acetylene process of autogenous welding and the Goldschmidt Thermit process, and representatives of both methods were asked to submit proposals for the filling of the groove cut by the entangled cable.

Upon receipt of the proposals, the oxy-acetylene bid proved the lower and a contract was awarded for the filling in of the cut with new metal by their method.

To facilitate matters the shaft was raised on concrete piers, the top of the piers forming a socket in which to turn the shaft more easily. This turning was accomplished by means of a tackle and rail.

The apparatus was put in place and the shaft preheated with charcoal and covered with asbestos to retain the heat as much as possible. The work was done under extreme physical conditions, the great heat requiring frequent relays and changing of men, it being almost impossible for a man to stand close enough to the cut to operate the burner for very long at a time. When the circle was at last complete and inspected, the ring of the metal melted into the cut was found to be separated from the metal of the shaft in places, the bond was insufficient to strengthen the weakened place, and the material so placed was easily removed. The failure was due mainly to the large radiation and conducting of the heat from the particular part where a bond of metal was desired, and to the severe physical strain. Smaller parts have been successfully handled here.

The Thermit exponents were then given a chance to fill in the worn place. The groove was carefully filled with wax and an adjustable flask placed around the worn part and the mold. Air was supplied from a derrick car, the derrick also being utilized to suspend the crucible containing the charge. The preheating was accomplished by gasoline blow torches and the wax was carefully removed and the mold cleaned by compressed air.

The reaction was perfect, and the result was a complete welding of the new metal into the groove. Precautions had been taken to provide a large riser and gate to cover the shrinkage and to insure solid metal in the worn part, as the top metal may be in some cases more or less porous. When the mold was removed, very satisfactory results were found. The removal of the extremely tough surplus metal was the most difficult part of the work. The gate and riser were finally removed, and outside of a few marks the weld was unnoticeable. Some concern was felt about the chances of warping the shaft when such an intense heat was suddenly applied in a comparatively short length, but such fears were dispelled when no appreciable change in the alignment was evident.

No machine finishing was necessary in this case, as the portion of the shaft affected did not come upon any bearing surface. Herein consisted the efficiency of this particular method, as there was no machine of sufficient size to handle this length of shafting available in this immediate locality, which would have barred the ordinary schemes of repair.

The third incident of interest in this district was the repair of a crankshaft of the main engine of the U.S. Engineers pipe-line suction dredge "Captain C. W. Howell."

The crankshaft of this 12x22x14-in. compound engine, directly connected to a 12-in. dredging pump, was 5½ in. in diameter. A crack was discovered in the low-pressure crankpin, and a careful investigation showed that instead of the characteristic fracture the crack ran into the web and back again around the pin. This precluded all the ordinary schemes of replacing the broken pin by shrinking in a new one, as the web did not have sufficient remaining metal to make such a repair safe.

The dredge was operated until arrangements could be made for a Thermit weld, and on the repair day the plant was shut down and the shaft removed to a shop. It was found to be entirely broken off. Part of the pin was machined off, leaving about an inch of space between the web and pin when the parts were aligned and fastened to a bedplate.

The mold was repaired in the usual way, and the ends to be united heated to as high a temperature as was safe. There was no hitch in the pouring of the crucible and, after cooling over night, the mold was removed in sections to prevent uneven contraction.

---

* From "Professional Memoirs, Corps of Engineers, U.S .Army and Engineer Dept. at Large," July-Aug., 1912. Vol. 4. No. 16.

When the gates were removed and the complete shaft placed in a lathe the nice allowance for shrinkage, etc., was evidenced by the fact that scarcely any refinishing was necessary on the thrust collars of the shaft. The pin was turned up and the surplus metal removed and web reshaped to original dimensions without changing the balance of the shaft.

A total of four days was lost by the plant because of this repair, most of the delay being due to the distance of the dredge from the shop. This shaft continued in constant use without any evidence of the repair whatever, and was in use when this dredge was lost a year after on the Texas coast.

An idea of the saving effected in this instance may be obtained from the fact that a new shaft ordered rushed at once from the factory at a cost of $465 was not ready for shipment 90 days after receipt of order, as compared with a charge of $150 and a delay of four days for the Thermit weld.

The necessity of skilled handling and placing of parts to be welded cannot be too forcibly emphasized, as the chances for ruining a part are greater from mishandling than from failure of the weld, and much unnecessary finishing work is prevented by careful attention to the mold conforming exactly to the desired shape of the part to be repaired.

The hard-driven machinery of dredging plants, with their interdependent individual machines, offers an excellent field for economic employment of this method, and it will very likely play an important part in cutting down long delays brought about by extraordinary accidents.

◆

THE MELTING POINTS OF FIRE BRICKS.*

By C. W. Kanolt, Assistant Physicist.

We are accustomed to thinking of a melting point as a temperature at which a substance changes from a rigid to a fluid condition; but a melting point can be precisely and rationally defined only as the temperature at which a crystalline [illegible] phase and an [illegible] or isotropic phase of the same composition can exist in contact in equilibrium. While this definition is satisfactory for pure substances, so complex a mixture as an ordinary fire brick usually has no single definite melting point according to that definition, since several crystalline phases may be present, all differing in composition from the isotropic phase produced by fusion. We can only note where the temperature at which the transition from a rigid to a fluid state seems most distinct, and take that as the melting point [illegible]. In the case of fire bricks the [illegible] commences at several [illegible], for [illegible] sufficiently [illegible]. I have taken as the melting point the lowest temperature at which a small piece of the brick could be distinctly seen to flow.

The determinations were conducted in an Arsem graphite resistance vacuum furnace. The samples were usually [illegible] in a [illegible] tube made of [illegible] and [illegible] in the [illegible] to protect them from the small amount of [illegible] gas of the furnace, [illegible]. The samples were observed through a glass window in the top of the furnace.

The temperatures were determined by means of a Morse optical pyrometer of the Holburn-Kurlbaum type, which was sighted vertically downward through the glass window. The carbon-filament pyrometer lamp was calibrated by two methods. In the first calibration it was sighted into a platinum resistance furnace in which black-body conditions were obtained, and the temperature of which was measured by platinum platinum-rhodium thermocouples. These thermocouples had been calibrated against the freezing points of pure metals. In the second calibration the lamp was calibrated against the freezing points of metals directly, without the intermediation of thermocouples. The metals used were copper, silver, and the copper-silver eutectic, which freeze at 1083 deg., 961 deg., and 779 deg., respectively. The metals were melted in the vacuum furnace in graphite crucibles, the pyrometer being sighted into a thin-walled graphite tube inserted in the metal. The pyrometer readings corresponding to the freezing points were determined by means of cooling curves. With silver and copper, heating curves were also obtained.

As the melting points to be measured were above the working limit of the pyrometer lamp, an absorption glass was interposed between the pyrometer and the furnace.

The true temperatures were then found from the apparent temperatures measured through the glass, by means of the equation

$$\frac{1}{T_2} - \frac{1}{T_1} = A,$$

where T_1 is the absolute temperature of the furnace, T_2 is the apparent temperature observed through the glass, and A is a constant. The value of A was determined by calibrations at various temperatures. A small correction was also applied for the absorption and reflection of the glass window of the furnace.

The samples, which were from one to two centimetres in diameter, were heated at the rate of about ten degrees per minute when near the melting point. It was found that in the case of certain bricks made of heterogeneous material of relatively low melting points were slightly higher after six hours' heating to 1550 deg., apparently as the result of the gradual running together of dissimilar particles to form a mixture having a higher melting point than the most fusible of the original materials.

The results are summarized in the following table:

Material	Number of Samples.	Melting point, Centigrade.
Fire clay brick	41	1555° to 1725° mean 1640°
Bauxite brick	8	1565° to 1785°
Silica brick	3	1700° to 1705°
Chromite brick	1	2050°
Magnesia brick	1	2165°
Kaolin	2	1735° to 1740°
Bauxite	1	1820°
Bauxite clay	1	1595°
Chromite	1	2180°
Pure alumina		2010°
Pure silica		1750°

The value 1750° given for silica is not the true melting point, but represents approximately the temperature at which the silica flows distinctly. It was found that silicon carbide does not melt below [illegible]; it becomes unstable at much lower temperatures.

---

*Abstract of Technologic Paper of the Bureau of Standards, published in the Journal of the Franklin Institute.

THE PRESERVATION OF REINFORCED CONCRETE IN SEA WATER.*

By Lieut. Edward Burr, Engineer Corps, U.S.A.

There still remains much doubt in the minds of engineers as to the reliability and permanence of reinforced concrete immersed in sea water or exposed to its effects. This doubt arises primarily from uncertainty regarding the effect of sea water upon the Portland cement or other binder employed in the mortar of the concrete, since, if the concrete is properly proportioned and put into place, and if it continues sound and intact, little remains to be done for the preservation of the steel. The problem, therefore, in its essential features, resolves itself into the employment of a cement or mortar unaffected by sea water, and its utilization in such a manner as will prevent access of sea water to the interior of the concrete and to the steel, with such additional precautions as experience may show to be efficacious. This short statement of the case is simple in terms, but its solution rests upon the determination of the most suitable cement and mortar to produce permanent results when used in concrete placed in sea water, which question has for years been before engineers for solutions and now has increased importance through the advent of reinforced concrete. In one respect, however, the problem is less difficult than would otherwise be the case, since it is only in rare instances that reinforced concrete cannot be seasoned before being exposed to sea water, and methods for its preservation can be employed under these circumstances that are not available for subaqueous work, with its attendant difficulties and possible defects.

The above concise analysis represents your general reporter's view of the problem involved in the determination of the best means for insuring the preservation of reinforced concrete in sea water. If it is correct in its general terms, the relatively long experience already had with plain concrete in sea water is available as a basis for drawing conclusions as to the reliability of reinforced concrete in maritime works, and we are not dependent alone on our short experience with reinforced concrete for the formulation of opinions and conclusions thereon.

The hydraulic mortars of lime and pozzuolana used by the Romans have through the centuries proved their worth for the conditions under which they were used in the Mediterranean. Portland cement is, through its universal availability, the material upon which modern engineers generally rely for hydraulic construction. While comparatively a modern product and subject to much suspicion in its earlier applications, it has been developed and perfected until it is now accepted by the profession as reliable for all purposes when selected and used with good judgment, and to this fact must be credited many of the most noted accomplishments in maritime works. In its application to such works, some failures have resulted, particularly in the earlier structures, but the failures chargeable to the material, in contradistinction to those due to other causes, have become notably less. Many successes with it have been had for decades, and of this fact no other evidence is needed than that supplied by its continued wide application to maritime works. The question, therefore, is not whether Portland cement mortar and concrete are reliable in such works, but is merely the determination of the conditions necessary to its most successful utilization. The conditions necessary to success appear to have been attained most generally when the concrete has, for various reasons, been seasoned in air to a greater or less extent before being placed in the work, and this is almost invariably the practice in reinforced concrete structures. Such success as has been secured with good examples of plain concrete, seasoned before placing in sea water, may therefore be expected with reinforced concrete, provided the precautions leading to that success are followed, together with such others as are peculiarly necessary to reinforced concrete construction, by reason of its design. The deteriorating effect of sea water on mortar and concrete is due to two general causes, physical and chemical. Physical effects result especially from the action of frost in the severe climates of northern latitudes and are largely localized to the areas between low and high-tide planes, where alternate freezing and thawing occur with each tidal oscillation. Effects of this class are to be found on the northern Atlantic coast of the United States, and require for their avoidance the application of methods that are not practicable in the general case, when the concrete is placed in the green or plastic state.

Chemical effects resulting from the action of sea salts on Portland cement are well known in their general aspects, and the general reporter will not enter in detail on this part of the subject, deeming it to be outside the scope of this report. It may be stated, however, that while engineers and chemists are, as a rule, agreed as to the general principles involved, there still exists some differences of opinion in regard to the desirability of having in the cement or mortar an excess of free lime, alumina or iron oxide.

It may be well at this point to refer to the opinions held by some engineers that mortars are inevitably destroyed in time by immersion in sea water. Such views were advanced at the St. Petersburg Congress in 1908 by some reporters and general reporters upon the questions of the application of reinforced concrete to hydraulic and maritime works, but were not sustained by the congress, which found sufficient grounds for believing that first results were encouraging if certain precautions were observed. Your general reporter concurs in that action and is of the opinion that further experience confirms it. He bases his opinion more broadly, however, upon the longer experience with plain concrete in sea water, and numerous specific instances may be cited where concrete has continued sound and unaffected after immersion from twenty to forty years or longer, in latitudes extending from the tropics to the severe climate of the north Atlantic. With these facts before us we can only confirm the opinions expressed sixty years ago that laboratory experiments are not conclusive in this matter, and only by immersion in the sea in the locality where it is to be used can the reliability of a cement for maritime works be absolutely determined. Long experience has shown that with sound cement and properly proportioned mortar and concrete, excellent results may be had if the materials are mixed and placed in position with all the care and precautions demanded by good workmanship in maritime works. Concrete, when used intelligently, has proved itself to be the best of mandmaidens to the modern engineer, but in the hands of engineers or workmen unskilled in its application, manufacture and placing, it has, by its failure, often exhibited their inefficiency. The failure of concrete in some maritime works cannot be held to prove it to be unsuited for such works, but, in view of its many successful applications, merely shows that some of the conditions necessary to success have not been met. It is believed, therefore, as a result of past experience, that good Portland cement concrete may be accepted as a reliable material for maritime works under suitable conditions, and may be expected to be reasonably permanent.

Both the physical and chemical effects of sea water on mortar and concrete result from their porosity, and if per-

---

[*] Abstract of report to International Congress on Navigation.

colation can be prevented, these effects can be avoided or retarded through the denial of access by sea water to the constituents subject to its action, if such there be in the concrete. A dense compact mortar is therefore essential to success, and is obtainable throughout the entire mass of reinforced concrete. While engineers are agreed upon this point, there are differences of opinion as to details in regard to materials, proportions of mixtures and other factors.

A sound, finely-ground cement, with limited percentages of sulphates and magnesia, is the first requisite. A minimum of free lime is generally agreed to, but opinions differ on this point and in regard to iron oxide and alumina. A rich mixture is necessary. It should not be leaner than 1:2:4, and some engineers recommend 1:2:3 or 1:1:1⅔. Opinions differ between fine and coarse sand, but, to the writer, this matter resolves itself merely into the question of a sand so graded as to have the minimum of voids, bearing in mind that a very fine sand makes, as a rule, a weak mortar. The gravel of broken stone should be small and well graded to secure a minimum of voids. The addition of pozzuolana or trass is strongly advocated by some, who hold that it combines chemically with the free lime of the cement, but this is denied by others, who maintain it to be an inert material, and opinions differ as to whether it strengthens the mortar. Others advocate the addition of anhydrous colloidal clay, or similar materials, finely ground and intimately mixed with the cement at the factory. Numerous proprietary compounds for improving the impermeability of mortar and concrete are in the market and are recommended by some maritime works, but they should be used with great caution until their stability in sea water is established.

The consensus of opinion is favorable to the use of salt water in gauging, but, since there remains some doubt on the subject, it is believed that fresh water is safer and should be used if reasonably available. The general tendency in modern practice is toward the use of a wet mixture for concrete either in mass or reinforced. The writer's practice goes back to the period when dry mixtures, in accordance with the theory of the times, were almost universally recommended, but experience has demonstrated to his satisfaction that the practical conditions of actual work can only be met by wet mixtures if the best results are to be secured with a minimum of defects. He also has a preference for small gravel or pebbles in lieu of broken stone, since sufficient adhesion for all practical purposes is found between the gravel and mortar, and since the gravel, through the shape [illegible] itself well to consolidation in the mold, particularly in small work.

Under the conditions just given, a dense, compact concrete is obtainable, if it is manipulated and placed with care. [illegible] steel bars, through care in selection and manipulation. It [illegible] ability, and concrete structures built and finished as de- [illegible]

[illegible]

mortar is one of the best of preservative coatings for steel or iron, even when exposed to continual of intermittent immersion in water, and instances can be cited in support of this opinion. Some fifteen years ago a composite water main made of thin sheet iron, coated inside and outside with cement mortar, was removed from the streets of the city of Washington, where it had been buried and in service for nearly forty years. The mortar coating was about three-quarters of an inch thick and the sheet iron was absolutely in as good condition as when the pipe was made. It is recognized that such examples hold only so far as concerns exposure to fresh water, but they confirm the opinion as to the protective value of sound mortar, and numerous cases may, no doubt, be found of similar protection when the exposure was to salt water. A case is cited (1) where reinforcing chains in a concrete-in-situ sea wall at Bridlington showed no signs of corrosion after being twenty-five years in place, although at points they were but one inch from the face of the wall, of which the lower half was covered by the sea at each tide. Further arguments and citations of facts appear unnecessary, since if protection can be and has been shown to have been secured in specific instances, it merely remains for engineers to reproduce in their own works the conditions necessary to secure like protection.

In this connection it may be added that short-time experiments in the United States of concrete exposed to sea water indicate the desirability of coating the steel bars with neat cement, well brushed on, before imbedding them in the concrete, and Mr. Luiggi, in his report upon this communication, recommends such a coating to be applied immediately, before the concrete is placed. The general reporter has prescribed this practice in all reinforced concrete work under his charge in recent years. To secure the best adhesion between the steel and the mortar for the development of the full strength of the work and for the protection of the steel from corrosion, the bars should be thoroughly cleansed of all oil, grease, rust and mill scale before the cement coating is applied.

While doubt remains in the minds of some engineers as to reliability of cement mortar immersed in sea water, and while other engineers maintain that it will be destroyed in a relatively short time, there is no difference of opinion in regard to the desirability of permitting concrete to harden or season in air or in sand for as long a time as the circumstances of the work will permit, before exposing it to the sea. Like views are held in regard to protecting concrete in place from the action of sea water, when the necessities of the case expose it to such action before it has fully hardened. Concrete that has thoroughly hardened in air before exposure to the action of sea water has fully established its greater reliability than concrete placed in sea water in a plastic state, and the subject requires no further comment here.

Earlier in this report a passing reference has been made to the excellent results obtained with concrete in the hands of skilled engineers and workmen. Every engineer is familiar with failures, more or less complete, of concrete when misused in incompetent hands. Even in skilled hands, care and watchfulness from the selection of the cement to the final completion of the work, are necessary to the best results. This is true of works in the open, and is all the more true for maritime works, where added adverse conditions prevail, and where the sea will inexorably prove the quality of the work in time. Therefore, a requisite to success is the unremitting exercise of every precaution needed to secure good workmanship at all stages of the work.

---

(1) Page 17, Reinforced Concrete Construction, by Adams and Matthews, Longmans, Green & Co., 1911.

Mr. Voisin reports that the works described by him have generally behaved well, and the oldest of them (piles and sheet piling on the sands of Olonne) were nearly thirteen years old in 1911. He recommends a rich mixture for submerged work, a brush finish of cement on the outside mortar surface and one or two coatings of coal tar, and a minimum protective coating of from 0.025 to 0.03 metres (1.0 to 1.2 inches) over the steel bars. He refers to the promising use of ceresite in mortars, and sums up by expressing his opinion that the conclusions reached by the 1908 congress have been confirmed and can now be more precisely stated.

Mr. Luiggi advocates the use of certain proportions of pozzuolana or trass to counteract the effect of any free lime in the cement, and refers to the lime-pozzuolana mortars that have continued sound in the maritime works of the Romans. In addition he sets forth four conditions necessary to success that may be summarized as follows: (1) A sound, finely-ground cement containing the minimum of sulphuric anhydride, magnesia and, especially, of free lime; (2) a rich mixture with a liberal excess of cement and mortar above that necessary to fill voids; (3) great care in the manipulation and placing of the concrete and the coating of the reinforcing bars with cement; (4) plenty of time for the concrete to harden in air. If his instructions are followed, Mr. Luiggi is of the opinion that "there will be obtained a practically impermeable concrete, and one, so to speak, unchangeable in sea water, in the interior of which the completely protected iron will last under good conditions for centuries.

"The reinforced concrete used with the precautions stated above will give excellent results when used for works in salt water, and may be adopted, therefore, with full confidence."

Mr. van Kuffeler is of the opinion that the covering over the steel bars should be not less than 0.02 metres (0.8 inch). He cites instances of the better performance of air-hardened concrete in comparison with concrete placed in sea water in a plastic state, and recommends a richer mixture under the latter conditions. Little objection is seen to the use of sea water in gauging, but a watertight concrete is considered a necessity. He advocates the use of trass or pozzuolana with the cement to increase the density and strength of the concrete, and refers to the tests of German special committee. Mr. van Kuffeler's conclusions, briefly stated, are: (1) Use only slow-setting Portland cements of the best quality; (2) mix thoroughly and place carefully the concrete in watertight forms; (3) the addition of trass or pozzuolana is desirable; (4) use a watertight concrete having 1 of cement and 1½ of trass to 3 of sand, or 1 of cement to 1½ of sand; (5) harden in the air if possible, and otherwise use a richer mixture.

Your general reporter is of the opinion that in good, sound concrete, plain or reinforced, the engineer has a most valuable device adaptable to meet any conditions in maritime works; that if designed with good judgment and applied with discretion, it will permit of the execution of works that might otherwise be financially or physically impracticable, and will ordinarily permit of economy in permanent works; that it is reasonably permanent in sea water if applied with all the precautions that experience to the present time has suggested, and that further experience may provide additional means for increasing its reliability; but that no precaution should be omitted in its application. He would not, however, be considered as advocating the use of concrete under any and all conditions, and recognizes that in some situations other materials, alone or combined with concrete, give better or more economical or more permanent results.

It is evident from the reports before the congress, and more especially from the current literature upon this subject, that experience with reinforced concrete in sea water has not to the present time covered a period sufficiently long to permit of laying down conclusions in detail as to the best methods to be followed for its preservation. With longer experience, such conclusions might be so formulated as to meet the approval of the Congress and some of them might be put forward at this time. It would seem, however, to be wise merely to refer to the experience heretofore gained in the matter of such details, as contained in the reports before the congress or as found elsewhere, and to defer action by the congress on such matters until conclusions thereon may be supported by such further experience as will enable the congress to adopt them with greater assurance as to their efficiency.

Only the following general conclusions are therefore submitted for the action of the congress:

1. Further experience tends to confirm the conclusion of the congress of 1908 that the earlier results of the application of reinforced concrete to hydraulic and maritime works are encouraging, and to indicate that reinforced concrete may be expected to be reasonably permanent in sea water if the precautions necessary to secure that end are intelligently and unremittingly exercised in accordance with the best experience in such works.

2. In view of the comparative novelty of this type of construction, its increasingly wide application, and the rapidly growing experience in its use, this subject should again be made a question for consideration at the next congress.

THE LIFE OF COTTON ROPES.

In a paper by Mr. Edwin Kenyon, delivered recently before the Canadian Society of Civil Engineers, on "The Transmission of Power by Ropes," it was stated that as to the life of cotton driving ropes, much of course depends upon their size and the conditions under which they have to work. All things being equal durability may be gauged by sectional area, and the most economical diameters range from 1½ inches to 1¾ inches more of the latter being used than any other size for textile work.

A remarkable case of longevity may here be quoted where twenty-four cotton ropes 1¾ inches in diameter are employed to transmit 820 horsepower at a velocity of 4,396 feet, direct from the engine fly wheel 28 feet in diameter to the various rooms of a Lancashire cotton mill. These were fixed in September, 1878, and all the ropes driving the card room have been running from then till now, a period of over thirty-three years. Another set has been working an average of twenty hours per day and appear to be little the worse for their twenty-three years' service.

The lives of other cotton driving ropes similarly circumstanced have extended over periods little short of this, while others again fixed from eleven to fifteen years ago though working without cessation, week-ends excepted, are still doing good service. A good example is to be found at a large paper works near Glasgow where cotton ropes have been working night and day for nearly fifteen years. Such cases of longevity lead to the conclusion that fatigue of material is due to constant activity does not readily manifest itself in well made cotton driving ropes.

Their quick recovery from driving strain is suggested as the cause, seeing that they pull down on the working side but bulge out to their normal diameter immediately they pass to the trailing or slack side of the pulleys.

ROADS ADAPTED TO LOCAL CONDITIONS.

At the last convention of the American Road Builders' Association, held at Rochester, Mr. Nelson P. Lewis gave a paper on "The Adaptability of Roads and Pavements to Local Conditions." Mr. W. A. McLean, the Ontario Provincial Engineer of Highways, in discussing the paper, said that a study of road conditions in various countries of the world will show a remarkable similarity in their several stages of road improvement, and in the problems which have confronted each. Throughout all, certain general principles are apparent, although local circumstances may require or permit a considerable variation in detail. These variations are, in general, more superficial than otherwise, and the underlying principles are in most cases of universal application. Thus on this continent we say, "Too many cooks spoil the broth," but in China they say, "Too many cooks spoil the dog." The general truth that too many cooks are an evil is taught in either case, and "broth" or "dog" are merely the local details. General truths are the same the world over, and it is important that, on the one side, we do not deny the usefulness of the general principle because of varying local applications; and on the other hand, that we do not render a failure the general truth by neglecting to adapt details to local conditions.

Let me emphasize a matter alluded to by the previous speaker—the selection of paving material for particular streets and roads, according to the preferences or prejudices of some of the abutting owners, "judiciously accelerated" by the enterprise of a salesman representing some particular kind of pavement. Most emphatically, "Too many engineers will spoil the pavement." It is a basic truth in all good business management, that responsibility should be centralized in order that full credit or blame may be placed where due. How can this be possible when paving materials are selected by the people or by councillors in opposition to or without the recommendation of their engineer? This is an evil in Canada as well as in the United States, and one which, solely in the public interest, should be strenuously combated. It is right that the preferences of the people should be made known; it is right that the taxpayers should express their views, and that these preferences and views should be given impartial and wise consideration by the engineer. [illegible] as an expert [illegible] as regards paving, the selection of the most suitable material for a given street or locality, should be one of his most important functions. Responsibility should be fixed upon him in this regard, and if he is inefficient and his selections are plainly unwise, another engineer should be sought. But the public, in its own interest, should be the last to relieve the engineer of [illegible] of the most suitable paving material for each street under his jurisdiction.

[illegible] lish practice, that, in letting contracts, purchasing material, [illegible] be made only in open council or in open committee, and any [illegible]

[illegible]

Climatic differences of temperature, moisture and wind in all combinations, materially influence the amount and method of drainage to be adopted. For example, if the subsoil and situation of a road are such that the natural soil is saturated and filled by the autumn rains and the melting of snow during the winter, and if this is acted upon and expanded by frost during the winter to a depth of three or four feet, as in Canada and the northern States, it is manifest that a very weak condition of the subsoil must exist when the spring thaws and freshets come. The foundation of the road may in this way become a quagmire for two or three weeks in the spring, during which time traffic will break through or partially disrupt any stone surface that could reasonably be applied. Under such climatic conditions, the need for careful underdrainage of the subsoil is manifestly much greater than in such a climate as that of England, where the frost penetrates only three or four inches into the ground. A mild climate having long periods of heavy rain may develop very similar conditions, though without the added difficulty of expansion by frost, or an impervious stratum of ice below the surface.

In the use of bituminous binders we have much to learn from other countries, particularly England, France and Germany, but any deductions should be made with full consideration of climatic and other differences. Thus in England tar is widely used for road purposes by spraying, by penetration, by the matrix, and by the mixing processes. But the extremes of temperature and the dry atmosphere of this continent present influences which do not exist in the more uniform and moist climate of Great Britain. Experience with tar in Canada has shown that it will resist successfully the climatic conditions, but the numerous failures have as clearly shown the necessity for a more scientific use with a view to climatic differences, demanding a careful study of methods of manufacture, of distillation, of proportioning the tar, pitch and creosote oil, and of selecting and grading the mineral aggregate. More frequent surface painting and gritting may also be one of the means for overcoming the influence of hotter and dryer climatic conditions.

First cost is often, necessarily, a determining factor, but as pointed out by Mr. Lewis, the ultimate cost at the end of the life of the pavement should, if possible, for true economy, be the most considered. The cost of pavements varies greatly according to locality, and an economical material in one district may be extravagant in another, owing to relative difference in price. In Cleveland, vitrified brick (an excellent paving material for many situations) cost $8 per M, while at Toronto the cost is $18 per M. Roads of local gravel, with short haul, may in cases be had for one-third of the cost of broken stone brought by rail; so that a gravel road, even if it has to be heavily resurfaced every four or five years, is probably, under such circumstances, a more truly economical road than broken stone would be.

The local cost and efficiency of labor is a factor which may favor or cause the rejection of an otherwise suitable paving material, which elsewhere can be economically laid. There is often a considerable range in this regard in short distances, while as between separated countries or regions the variation may be exceedingly marked. Wages are generally higher in the cities than in the country; are lower in Europe than on this continent, and are usually lower in southern than in northern countries, so that methods and materials should be varied accordingly.

Road construction has been criticized from time to time because of large bond issues, and the economic value of large expenditures has been questioned. Very great care must be taken in the local adaptation of road making materials in order that this criticism may not be justified. The use of heavy foundations, bituminous binders and other first-class materials is no doubt justifiable and essential on heavily traveled suburban and main interurban highways—the class of road which is or should become of national, or state, or occasionally of county importance. But this will ordinarily apply to a comparatively small percentage of the total highway system, and a road that is too good, and too costly, for the amount of traffic, is as much an economic blunder as bad roads. But all roads of the country need improvement. It is as necessary that the 90 or 95 per cent. of less traveled township and country roads be made proportionately good by grading, draining and surfacing, as that the 5 or 10 per cent. of trunk roads be built, but care must be taken that costly design suitable only for the latter, be not carried into the division where cheaper construction would be satisfactorily serviceable. Construction adapted to location and traffic, with proper regard to future requirements, is of vital necessity.

◆

SOME TEST CURVES OF TURBINE-DRIVEN CENTRIFUGAL PUMPS.

A complete line of turbine-driven, low-pressure centrifugal pumps have recently been placed on the market by McEwen Bros., of Wellesville, N.Y. These pumps have been developed after over two years' careful investigation from designs made by Mr. C. V. Kerr, chief engineer of the company. They represent an advance in turbine machinery, as the speeds used conform to exceptional turbine economy. The usual type of centrifugal pump cannot run at turbine speeds for low-pressure work, and so the steam consumption is sacrificed.

Fig. No. 1 shows the calibration curves for a well-known small turbine. It will be noted that the curves are lines of constant steam conditions, and also constant steam flow. At, for example, 150 lbs. steam pressure and atmospheric exhaust, with the same total steam flow, the horse-power increases from 21 at 1,500 r.p.m. to 36½ at 3,000 r.p.m.

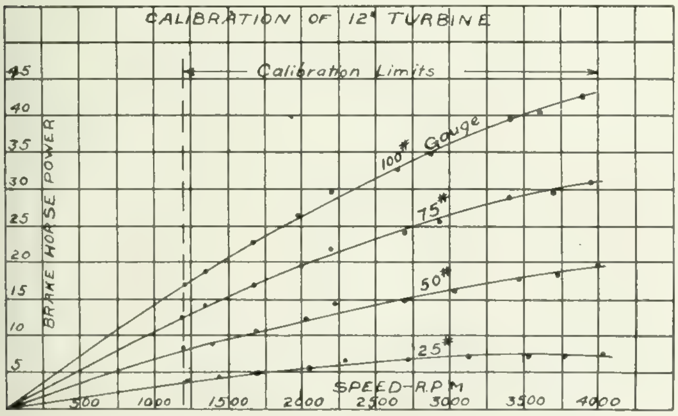

Fig. 1.

The advantage of high speed will at once be evident. A smaller turbine may be used in most cases, and the water rate is greatly improved.

Fig. No. 2 shows test results obtained on a standard 30-in. pump. It will be noticed that the maximum pressure occurs at no discharge. This gives best conditions for starting and general service. At constant pressure the horse-power at no discharge never exceeds 40 per cent. of the normal, and may be less than 30 per cent. The horse-power decreases at discharges greater than normal when the speed is kept constant. As the horse-power increases at higher speeds or pressures, the pump of itself forms a highly efficient governor, and service conditions are maintained over variable operating possibilities. At the same time, under variable speed control the horse-power curves vary about as the quantity delivered at constant pressure. The gain in efficiency and horse-power used under these circumstances enable the turbo pump to further encroach on the field of the plunger type.

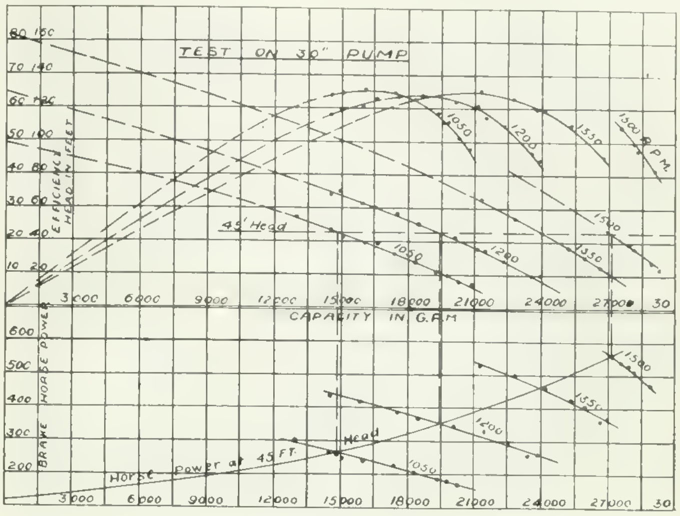

Fig. 2.

◆

STRUCTURAL COMPOSITION AND PHYSICAL PROPERTIES OF STEEL.

The following is abstracted from an interesting article by Albert Sauveur in the May Journal of the Franklin Institute:—

Bearing in mind that hypo-eutectoid steel is composed of free ferrite (pure metallic iron, magnetic and stable below 850 deg. C.) and pearlite (an alloy of carbon and iron, of lamellar structure), and that hyper-eutectoid steel consists of free cementite (iron carbide, formula Fe_3C) and pearlite, and knowing the proportion of carbon in pearlite and cementite, the structural composition of any steel may be calculated, provided the percentage of its carbon content is known.

For hypo-eutectoid steel, $F + P = 100$, and $0.01EP = C$, in which F is the percentage of free ferrite present, P the percentage of pearlite, E the percentage of carbon in the pearlite, and C the percentage of carbon in the steel. For hyper-eutectoid steel, $P + Cm = 100$, and $0.01EP + 0.0667Cm = C$, in which Cm is the percentage of free cementite.

The exact carbon content of pearlite is not known, and it varies somewhat both with composition and treatment; in commercial steel it is probably not far from 0.85%. For simplicity in calculation it is warrantable to assume that pearlite contains 1 part by weight of cementite to 7 parts by weight of ferrite; or

$$12.5\% \text{ cementite} + 87.5\% \text{ ferrite} = 100\% \text{ pearlite},$$

and since cementite contains 6.67% carbon, 12.5% of cementite will contain $(6.67 \times 12.5 \div 100 =)$ 0.834 % carbon. With this assumption and the fact that the carbon in the steel produces exactly 15 times its own weight of cementite, the calculation of the structural composition of any steel becomes extremely simple.

From the foregoing considerations it may be shown that the percentage of pearlite in hypo-eutectoid steel (i.e., steel containing less than 0.834% carbon) is equal to 120 times its carbon content, or $P = 120C$, the remainder of the steel consisting, of course, of free ferrite ($F = 100 — P$). To find the percentage of pearlite in hyper-eutectoid steel, the percentage of carbon in the steel should be substituted for C in the formula $P = (800 — 120C) \div 7$, and the remainder of the steel will be made up of free cementite ($Cm = 100 — P$). For example, a steel containing 0.50% carbon will have a structural composition of ($120 \times 0.50 =$) 60% pearlite and ($100 — 60 =$) 40% ferrite. In a steel containing 1.25% carbon the pearlite will amount to $[800 — (120 \times 1.25)] \div 7$, or 92.9%, and the free cementite $Cm = 100 — 92.9 = 7.1\%$.

Physical Properties of the Structural Constituents of Steel. It is evident that the physical properties of ferrite must resemble closely those of wrought iron and steel having a very low carbon content. It, therefore, is very soft, very ductile and relatively weak; it is magnetic, has a high electric conductivity, and cannot be materially hardened by rapid cooling from a high temperature. Pearlite is hard and possesses maximum hardening power. Little is positively known as to the physical properties of cementite, excepting that it is exceedingly hard and brittle, and that it possesses no hardening power. The properties of these constituents of steel in its normal condition are substantially as follows:—

	Tensile strength, lb. per sq. in.	Elongation in 2 in., %.	Hardness	Hardening power.
Ferrite	50,000*	40*	Soft	None
Pearlite	125,000*	10*	Hard	Maximum
Cementite	5,000 (?)	0	Very hard	None

---

* More or less

Tenacity of Steel vs. Its Structural Composition.—It is reasonable to make the assumption that these constituents impart to the steel their own physical properties in a degree proportional to the amounts in which they are present. The tensile strength (T) of any hypo-eutectoid steel may, therefore, be expressed by the formula

$$T = (50,000F + 125,000P) \div 100,$$

or, simplifying, $T = 500F + 1,250P$; or, in terms of pearlite alone (since $F = 100 — P$), $T = 50,000 + 750P$; or, finally, in terms of carbon (since $P = 120C$), $T = 50,000 + 90,000C$.

According to this simple formula, steels containing 0.10, 0.25, and 0.50% carbon have tensile strengths of 59,000, 72,500, and 95,000 lbs. per sq. in., respectively. These values agree closely with our knowledge of the average tenacity of such steels when in a pearlitic condition. Steels forged and finished at a fairly high temperature are practically in this condition. The formula cannot be used for steel forged until its temperature is quite low, and especially if it be cold worked—the tensile strength is generally increased by such means. Neither can it be used for hardened tools nor for steel castings unless properly annealed. The formula is of value only in the case of commercial steels containing the usual proportions of impurities and in which the percentage of manganese varies roughly with the carbon content (from [illegible]). A greater percentage of manganese would naturally increase the tenacity.

The tensile strength of hyper-eutectoid steel cannot be calculated so closely, because of lack of accurate information as to the physical properties of cementite. Assuming it to have a tensile strength of 5,000 lbs. per sq. in., the tensile strength of a hyper-eutectoid steel $= T = (125,000P + 5,000Cm) \div 100 = 1,250P + 50Cm$, or, in terms of pearlite (since $Cm = 100 — P$), $T = 5,000 + 1,200P$. As $P = (800 — 120C) \div 7$, the foregoing may be further simplified to $T \div 142,000 — 20,600C$. Applying this formula to steels containing respectively 1.25 and 1.50% carbon, the respective tensile strength are found to be 116,250 and 111,100 lbs. per sq. in., which are fair values for the average tenacity of pearlitic steels of those degrees of carburization.

Steel of Maximum Strength.—From the preceding considerations it seems evident that eutetoid steel must possess maximum tensile strength, since the influence of the presence of ever so small an amount of free ferrite in hypo-eutectoid steel or of free cementite in hyper-eutectoid steel must necessarily be a weakening one, because of the relative weakness of free ferrite and free cementite as compared to the strength of pearlite. Most writers state that a slightly hyper-eutectoid steel, containing about 1% carbon, possesses maximum tenacity. It seems probable, however, that the steels to which they refer were in a sorbitic rather than in a pearlitic condition; it may well be that when in a sorbitic condition maximum strength corresponds to a higher degree of carburization—i.e., 1%—because sorbite may, and indeed often does, contain more carbon than it does pearlite.

Ductility of Steel vs. Its Structural Composition.—It should be possible to work out a formula expressing the ductility of any hypo-eutectoid steel in the annealed (pearlitic) condition from the known elongation under tension of ferrite and pearlite (see table). This ductility should be $D = (40F + 10P) \div 100$, or, in terms of pearlite alone (since $F = 100 — P$), $D = 40 — 0.3P$; and, since $P = 120C$, the ductility in terms of carbon would be $D = 40 — 36C$. Pearlitic steels, for instance, containing 0.25 and 0.50% carbon should have elongations of 31 and 22%, respectively.

Reduction of Area vs. Structural Composition of Steel. Similarly, the reduction of area of any slowly-cooled (i.e., pearlitic) hypo-eutectoid steel may be calculated on the assumption that pearlite has a reduction of area of 15% and ferrite a reduction of 60%. Then reduction of area $= R = (60F + 15P) \div 100$, or, in terms of pearlite (since $F = 100 — P$), $R = 60 — 0.45P$, or, in terms of carbon (since $P = 120C$), $R = 60 — 54C$. Pearlite steels containing 0.25 and 0.50% carbon should, therefore, have reductions of area of 46.5 and 33%, respectively.

◆

CHEMICAL WOOD PULP.

Experiments in the manufacture of chemical wood pulp are carried on in the Forest Products Laboratory at Madison, Wisconsin. This is the largest and most complete laboratory of its kind in the world. The building, costing $100,000, was erected by the University of Wisconsin. The equipment, staff and operating expenses are supplied by the United States Forest Service.

The laboratory started work in June of this year. The results of the work have not yet been published, but it is known that a good quality of kraft paper has been manufactured from the saw-mill waste of western yellow pine, that the saw-mill waste of Wisconsin has been found satisfactory for chemical pulp manufacture, that great advances have been made in the manufacture of a good quality of chemical pulp from dead and green tamarack, hemlock and jack pine. The staff at Madison have also examined samples of pulp from practically all the mills in the country, and have worked out satisfactory methods of standardizing, comparing and grading wood pulps.

MATERIAL FOR ROAD AGGREGATE

In a paper before the American Road Builders' Association, and printed in this issue of *The Canadian Engineer*, on "The Maintenance of Roads and Pavements," Mr. James Owen places emphasis on one feature of road-making which, we feel, to the present time, has been lost sight of by many road-builders. This fact is that the increase of automobile travel has caused the character of the mineral aggregate in any road mixture to assume a place of secondary importance. Under the old conditions of traffic the ideal material for road metal was hard trap-rock, and this was used, and is being used, wherever available, even at great cost on account of long hauls. Under the present conditions of travel, however, it is found that with the grinding eliminated and the use of surface oils, good gravel gives as excellent results as trap rock. Mr. Owen draws attention to the fact that granite can be used with impunity, and such natural materials as chert and shale can also be used. The sand and clay roads of North Carolina have, with oiling, been made into perfect roads. A full appreciation of this fact will reduce the cost of many miles of road in the future.

◆

LONG DISTANCE POWER TRANSMISSION.

The question of long distance electrical power transmission has assumed vast proportions during the past few years. Voltage and distance of possible transmission has increased tremendously. When the Niagara Falls Power Company began its development in 1891 it was considered a wonderful feat when power was transmitted to Buffalo, a distance of about twenty miles. To-day we find plants operating at a voltage of 140,000 and up to distances of 200 miles. The limiting voltage of power transmission is an interesting point. In discussing a recent paper by Dr. Steinmetz before the American Institute of Electrical Engineers, Mr. F. W. Peek, jr., made some interesting comments on this point. He states that a comparison of the past with the future is of interest in giving a comparison of past difficulties with present difficulties, and limitations of the past with the apparent limitations of the future.

He states that he came across, quite accidentally, an old book of letters by a very prominent engineer—it was not such an old book either, measured in time, but old measured by engineering progress. The writer states in one letter that an operating transformer had actually been built that could stand 15,000 volts, and it was hoped that ultimately a transformer could be built to operate successfully at 20,000 volts. The apparatus at that time was the limiting feature of transmission. Voltages went up by leaps and bounds, and transformers were shortly thereafter operating practically at voltages of from 50,000 to 60,000. At this stage the pin type insulator began to give trouble, so, naturally, the suspension insulator was invented. Voltages then jumped up to 100,000, and another trouble appeared, or what seemed to be a trouble or limiting feature, that is, corona. This led to investigations of corona losses, and it now appears that we still have some margin in the matter of corona limit; for instance, power could be transmitted at 200,000 volts with a conductor about one inch in diameter with 12 to 15 feet spacing. With long lines and high voltages other troubles appear; as an example, suppose we take a line, say, 200 miles long, with a voltage of 140,000. The capacity current may equal the total load current of the whole station. This will mean trouble unless some method is adopted that will take care of this heavy leading current, or the generator units are properly arranged as to size. If part of the load is supplied by part of the generator units and the load is suddenly lost, these units may be over-loaded by the capacity current. Another emergency to be provided against is the rise in voltage at the receiving end (due to capacity current through reactance) when the load is suddenly thrown off. Taking a practical instance, after the comparatively small lighting load is taken on in the evening, the heavy factory loads go off; over-voltage is put on the lamps. Fortunately, the effect of capacity current can generally be well taken care of by shunted synchronous reactance. Now, it is rather interesting, for the moment, to look forward into the future and perhaps ask a question, What will actually be the limiting voltage of power transmission, or limiting distance? Will it really be due to the loss of energy into the air by corona, the line insulator, the apparatus, or will it be an electrical feature after all? Will it not rather be, with some few exceptions, an economic or natural feature? For instance, the power naturally concentrated at a given point, as in a waterfall, will generally be exceeded by the demand before the distance becomes so great that it is necessary to use voltages above the electrical limit.

EDITORIAL COMMENT.

The Western Canada Irrigation Association has just closed its annual convention at Kelowna, B.C. Next year's meeting will be held at Lethbridge, Alta.

* * * *

Ottawa is slow to move on the water supply question, although they have had sufficient warning to warrant immediate action. The mayor is endeavoring to shift responsibility to the shoulders of the city engineer. The public, however, will no doubt remember that it is over a year since the previous typhoid epidemic, and since that time no action has been taken by the city council to improve the water situation.

* * * *

A magazine published in the United States and enjoying a large circulation among persons of a scientific tendency recently sent out a number of letters to scientists of international reputation in order that a vote might be secured and the seven wonders of the modern world tabulated. The result was that wireless telegraphy, telephone, aeroplane, radium, antiseptics and antitoxins, spectrum analysis and the X-ray were given as the seven wonders. A glance over the list at once raises the question of where the high-power microscope stood when the total was ascertained. It is doubtful if any piece of mechanism could be named that has rendered more service to mankind. The high-power microscope is to the sanitary engineer exactly what the compass is to the commander of the transoceanic liner, and without its discovery and development municipalities that are today [illegible] their existence by discharging their refuse into lakes and streams and then attempting to secure a satisfactory drinking water supply from the same source, would be depopulated and devastated without the ability to secure control of the bacillus that was the cause of all the evil. The science of bacteriology was unknown before the invention of the oil immersion microscope objective. This instrument, that has bridged the gap between disease and the source of disease, and has given sanitary engineers and medical experimenters the power to combat bacteria and observe the results of their labors, is worthy of a place on this list.

* * * *

Many instances could be cited regarding the general laxity of business methods employed by religious denominations in their dealings with architects and contractors. One of the most pointed instances has recently come to light in a rapidly growing city in the Province of Alberta. Tenders were called in the usual manner, the date of expiration mentioned, and the parties tendering were given to understand that their respective prices and offers would receive full attention from the governing body of this particular religious body, which has its provincial seat of control in Edmonton, some miles from the proposed place of work. As the time for the awarding of the contract lengthened, several contractors made enquiries, and were informed that the purpose of calling these tenders was to aid the architect only. When this gentleman (with the assistance of the contractors doubtless fully appreciated) made a report on the probable cost of the structure the building committee would reconsider the matter.

* * * *

The mayor of Ottawa has issued an invitation to citizens at present securing water from private sources, other than that publicly sold, to forward samples to the civic medical health laboratory for free bacteriological examination. The invitation contains an extraordinary statement to the effect that "many wells, particularly those drilled in rock, are contaminated." As a matter of fact, wells drilled in rock as a general rule furnish pure water. Recently in the council meeting of a large Western Canadian city a discussion was under way relative to the merits of the spring which certain parties were urging the authorities to purchase. An analysis of the water had been prepared and a number of the council took issue to the high reading of the chlorine factor. Their objections, however, were overcome by one member of the council, who ventured to impart the valuable information that the chlorine in water "was just what made it hard," and, as he explained, doubtless would be easily removed. The above incidents illustrate the amount of scientific knowledge held by the average member of a city council.

THE END OF A FAMOUS SHIP.

The Canadian Pacific Railway liner, Empress of China, was recently sold to a junk dealer in Yokohama, Japan, for the paltry sum of $67,180. It is just exactly one year since the palatial white liner, sister ship to the present Empresses plying from Vancouver to the Orient, went on the Shirahama reef in a dense fog and during a freak tide. About eight months ago she was floated under great difficulties and taken to Yokohama.

After the big liner had been surveyed it was found that it would cost anything from $150,000 to $200,000 to effect such repairs as would enable her to continue in the Trans-Pacific passenger trade. The underwriters have been negotiating for the sale of the vessel for some considerable time, and several Japanese have been in the field bidding for the wrecked liner. The Empress of China was raised by the Mitsui Bishi Dock Company, of Nagasaki, after the rocks which held the ship fast had been blasted away, and with the help of exceptionally high tides. The Canadian Pacific Railway put in claims for a constructive total loss, and a settlement of the insurance claim was made by the underwriters when the liner was offered for sale. The Empress of China will be broken up for scrap by the Japanese purchaser.

DESTRUCTION OF CONCRETE TRACK FOUNDATION.

A method of breaking up old concrete track foundation is described by Mr. C. B. Vorce, construction engineer for the British Columbia Electric Railway Company, Vancouver, B.C., in an article in a recent issue of Engineering and Contracting, and we reproduce the description herewith.

Granville Street in Vancouver, British Columbia, is a principal business street, over which six car lines, or about 150 cars per hour, pass. The tracks on this street between Robson and Drake Streets, a distance of one-half mile, were riding so badly that their reconstruction was imperative. It was not advisable to rebuild during operation and as there is a double track car line only two blocks away, the Board of Public Works granted the B.C. Electric Railway Company permission to abandon traffic during construction, providing it was restored in 24 days.

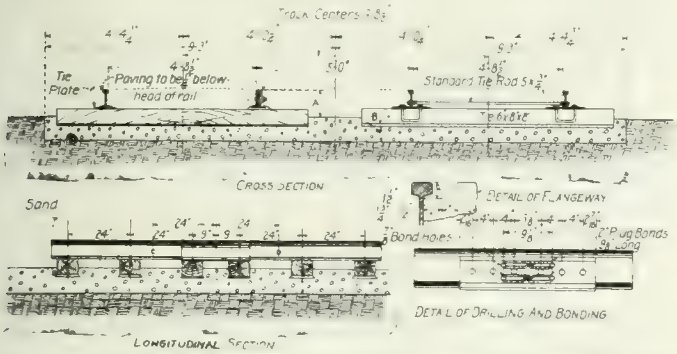

Fig. 1.—Standard Track Construction of British Columbia Electric Railway, Vancouver, B.C.

The street was paved with wood blocks laid on 6 inches of concrete, and each rail of the double track was carried on a concrete girder 2 feet wide and 15 inches deep. Owing to the nature of the foundation these girders were not heavy enough to carry the weight imposed upon them and on account of this the company adopted the type of construction shown by Fig. 1. This construction consists of a 6-inch concrete slab which is laid over the entire track allowance, 18½ feet wide, upon which 91-lb. T rail 7 inches high are laid on 6 x 8-inch by 8-foot ties spaced 2 feet centre to centre. The track is then surfaced to grade on a sand cushion averaging 1 inch deep and the concrete is brought up to the under side of the pavement.

By referring to the standard cross-section (Fig. 1) it will be seen that the botton of the concrete slab is 20 inches below the rail grade.

As stated above, the reconstruction of the tracks called for taking out and replacing the following quantities: 5,100 sq. yds. of wood block paving, 10,200 lin. ft. of rail or 5,100 lin. ft. of single track, 1,800 cu. yds. or 5,100 sq. yds. of concrete, 600 cu. yds. of earth and the laying of 2,400 cu. yds. of concrete, one-half mile of double track, 850 sq. yds. of granite flangeway blocks and 4,250 sq. yds. of wood blocks.

As the concrete has to set 10 days before traffic can be turned back on the street, this necessitated the completion of the work above outlined, except the paving, in 12 days, and not 14 days, as two Sundays intervened. The work was carried on day and night, and a schedule (Fig. 2) was prepared showing the rate of progress which must be made on each of the operations in order that the work should be completed within the time limit. This schedule was so closely followed that all the work, except the paving, was finished one hour before the time called for by the schedule, and during the 10 days the concrete was setting the street was repaved, so that when traffic was restored all the work was completed.

The B.C. Electric Railway Company has a large construction force, who do the greater portion of its work, so it was certain of the speed with which the various operations, with the exception of breaking up of the concrete, could be accomplished.

The company had just built a piece of new track which called for the removal of about 300 sq. yds. of concrete of a similar nature, which had been laid by the same contractors. This piece of concrete was removed by hand and it took 15 men 6 days to do the work. As the schedule called for the removal of about 32 sq. yds. of concrete per hour, it was seen that some mechanical means must be used, and the following scheme was adopted:

The dipper arm was taken off the electrically driven Thew automatic shovel owned by the company and the pile driver leads about 20 feet long were hung from the end of the boom, being held in position by two braces running back to the main frame of the shovel. A hammer weighing 2,600 lbs., with a wedge shaped cutting edge about 8 inches deep running parallel to the track, was specially cast. The cutting edge was placed this way in order to not injure the remaining concrete in the street. This scheme worked excellently and no trouble whatever was found in breaking up the concrete as rapidly as it could be taken away.

The concrete breaker, which could swing through 350 deg., was placed on one track and on the other track the derrick car was placed. This derrick car had a 60-foot boom, which could also swing through 360 deg. and could move itself up and down the track. This car was used to break up the larger pieces of concrete and load them on flat cars placed behind the concrete breaker, also to unload skips in which were placed the smaller pieces of concrete and earth, this material being dumped into wagons standing alongside.

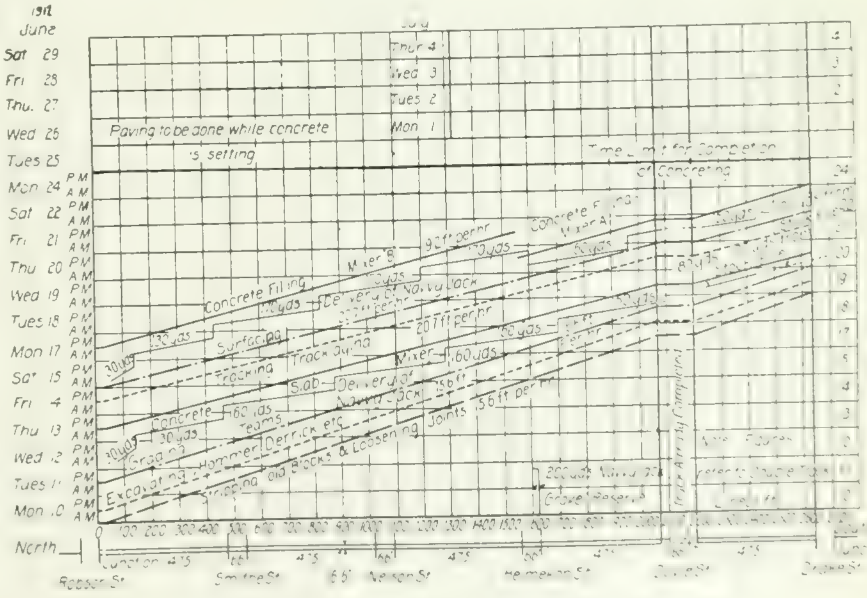

Fig. 2.—Progress Chart of Track Reconstruction Work.

The concrete breaker and derrick car backed up on the old track as soon as the concrete was broken up for a rail length ahead of them.

The price of common labor was $3 per day of 10 hours, and teams received $8 per day shift of 10 hours and $9.50

[illegible] The average haul for teams was [illegible] of a mile and for the track cars about 2 miles. The cost of the work was as follows:

Digging up wood blocks, 8 9/10 cts. per sq. yd.

Tearing up old track, 11 cts. per ft. of single track.

Breaking up concrete, 40 cts. per sq. yd., or $1.13 per cu. yd.

Excavation, loading and dumping, 82½ cts. per cu. yd.

Removing material by teams and work train, 65 cts per cu. yd.

Mr. G. R. G Conway, M. Am. Soc. C.E., is chief engineer of the B.C. Electric Railway Co., and the work was carried on under the supervision of Mr. C. B. Vorce, M. Am. Soc. C.E., engineer of construction, assisted by Mr. H. J. Tippet, engineer maintenance of way, and Mr. A. J. Kennedy, roadmaster.

REPORT ON MOOSE JAW MUNICIPAL HEATING PLANT.

A report was presented to the City Council of Moose Jaw, Sask., recently, on the advisability of installing a municipal heating system, by Mr. J. D. Peters, the municipal electrical superintendent. The report in abstract follows:

"Before deciding upon what line of action to adopt regarding the new power plant to replace the one destroyed by fire on May 25th, there are several things to be taken into consideration, at least the suggestions and advice that are forthcoming regarding this matter make it necessary to consider everything carefully. I will endeavor therefore to point out to you clearly and as briefly as I can my own views regarding the matter. I will say I am not prejudiced in any way, but am anxious that we shall get the best and most economical and up-to-date plant possible. I also think that I am in a better position to discuss this matter than any other person, as I know the conditions under which we have been operating. The first thing I would suggest would be the changing from the two phase system to the three phase. The advantage of the three phase system is:

1st.— That 25 per cent. less copper wire and space is re[illegible]

2nd.—The three phase systems are generally conceded to be the standard, and with the result that only three phase apparatus is carried in stock to any extent by manufacturers. Two phase is regarded as "special." It is often very difficult to obtain two phase apparatus without waiting for it [illegible] think there will be much effort among the manufacturers to improve upon it. To consumers having plants in different [illegible] tors or other apparatus. Beyond this, and the saving in in[illegible]

[illegible]

"Regarding the central steam heating system, if you will refer to my annual report for last year, you will find the following: 'To instal a steam heating plant system and connect with our plant to accommodate sufficient business to warrant placing back pressure on our engines would entail an expenditure of at least $300,000. From such a plant we would derive a revenue of about $1.25 for every kw. produced. Therefore to sell sufficient exhaust steam to make 10 per cent. on capital expenditure, or $30,000, it would be necessary to sell the exhaust produced by manufacturing 2,400,000 kw.h., or twice total output for the year 1911. Then this amount would have to be sold during the heating season of about eight months. Further, on account of our widely varying load, we could not utilize all our exhaust during the hours of heavy load, and would, no doubt, have to make up with live steam during the hours of lightest load. Our very low load factor is against the proposition. When all these things are considered, I believe our annual output would need to be about six times the output for 1911 before we could go into the heating business to advantage, and the load factor of the plant would need to be improved.'

"I have during the last few days been checking up this statement quoted above, and do not think it necessary at the present time to modify it in the least. I would only emphasize the last few words referring to the load factor. There are so many things to be taken into consideration in figuring out the advantages and disadvantages of the steam heating system that it would require months to get a full reliable report upon the matter, and it looks to me as though it were scarcely worth investigating at the present time, considering our present load conditions. I would not recommend any action towards the installation of a heating plant without having a full report from a heating expert and one whom we are sure has no 'axe to grind.'

"The prospects of going into the heating business at some future time should not, however, have any effect upon our present requirements of generating apparatus, as we would require other units to take care of our heavy loads and summer loads, the exhaust from which could be utilized for heating system. As to the location of the plant, if the heating business was started a more central location would be slightly more desirable. However, the cost of such a site would be so great that it would pay better to run the necessary mains from the present site to the business section of the city. I do not think there is a better location for a power plant in the city than the present one.

"I do not regard the heating business as being suitable for municipal ownership, as only a comparatively small portion of the ratepayers could expect to share directly in the benefits of such a system. Indirect benefits might come in the way of reduced rates for electricity, but on the other hand the heating business might turn out a failure, and drag down the electrical department with it. However, these are points for more of an expert than myself to deal with. I have already pointed out to you that we will require, in any [illegible] apparatus that is not adapted for steam heating, and also that the present location of the plant need not be changed.

"I will therefore recommend that immediate steps be taken [illegible] light and power service at the earliest possible date by the installation of a steam turbine and generator large enough to handle our maximum load until such time as we can get a smaller unit installed. If the machines are available I would instal a unit of 1,000 kw. capacity at once, and a [illegible] kw. unit as soon afterwards as possible. These two units will handle our business during the [illegible] but it will be necessary to add to this capacity next year. Then if we have a favorable report upon the matter of steam heating, and decide to go into it, a unit suitable for it can be installed next year. At the present time this department is standing a net daily loss of about $225, so you will see that prompt action is necessary.

"We have been already offered several generating units for quick delivery, both new and second-hand. Among these we have an offer from the Canadian General Electric Company to substitute a three phase outfit for the two phase outfit already ordered from them, and to ship same immediately. This is an exact duplicate of the one already ordered, with the exception of the winding of the generator, and the same guarantees and other terms of the contract will apply. All that is necessary to obtain the outfit at once is to give the company an order to change the winding of the generator from two phase to three phase. The price will be the same, except for some slight adjustments to cover switchboard not now required in the contract, and the exciter set to be given in part payment, but which is now destroyed by fire. There will also be a charge of $350 for work already done on the two phase machine. Condensor equipment can be shipped in six weeks, and until this arrives the turbine could be operated non-condensing. If this proposition was accepted we could have full service restored in about five weeks' time, and would also have a thoroughly up-to-date machine in our plant. In our present plight I believe it is the very best action to take."

CHLORINATION AT CLEVELAND, OHIO.*

By Dr. D. D. Jackson, Sanitary Expert, New York City.

When the chlorinating plant for treating the water supply of Cleveland was placed in operation in September, 1911, disagreeable tastes and odors were noticed from time to time and investigations were undertaken to regulate the application of the chemical and determine its effectiveness as a sterilizing agent. It was found that the unsatisfactory results were due to the use of unnecessarily large amounts of chlorine. The quantities of chlorine have been reduced while the sterilizing effect upon the water has been sufficiently active. The efficiency of the process was demonstrated during the present year, both by analytical results and by the fact that while ice movements in April caused specific infection in the water supply at the intake during three days, yet there was no accompanying rise of typhoid in the city. Since the installation of the new four-mile intake the water supply of Cleveland has been in a satisfactory sanitary condition at all periods of the year, with the exception of the short intervals during which the annual breaking up of the ice has occurred. The sewage-laden ice from the river and harbor has, on several occasions, infected the supply at that time, especially in 1910 when the ice movements were oscillating and protracted.

Under present conditions infection occurs only during and directly after the ice movement and it is at these times only that it is imperative to treat the water with hypochlorite. In order to insure the use of standard amounts of chlorine when sudden increase or decrease in pumping takes place, it is recommended that an automatic device be installed which will regulate the flow of hypochlorite solution directly in proportion to the flow of water, and that experiments be made with a view of substituting the chemical solution by compressed chlorine gas made directly from the electrolysis of common salt. This gas is more effective at low temperatures, is readily eliminated from the water by its more rapid reaction, can be easily regulated and is in all respects like treatment with ozone, but more practical of application and much less expensive. The estimated cost of an installation for Cleveland is $2,000 and the cost of treatment from 40 cents per million gallons downward to about 25 cents as liquid chlorine comes into general use and is made on a large scale.

With the present funds available for waterworks purposes at Cleveland it is proposed to extend the old intake line to a point 16,000 ft. northwesterly from the old west-side crib, thereby having two long lines ready for use so that in case leaks should develop in one the other would be available for use while repairs were in progress on the damaged line. The extension of this intake together with the installation of permanent apparatus to treat the lake water is believed to be a satisfactory method of insuring a pure supply of water and is much less expensive than building filters.

The present chlorinating plant consists of a small mixing tank 4 ft. in diameter and 3 ft. 4 in. deep, equipped with a mechanical stirrer. There are two 11 ft. 8 in. diameter solution tanks, 7 ft. 5 in. deep; a 1 per cent. mixture is used, the feed being controlled by two orifice tanks with float valves. The daily pumpage is about 70,000,000 gal., so that from 11 to 18 lb. of hypochlorite per million gallons is used, corresponding to an amount of chlorine of from 0.5 to 0.7 parts per million. Sudden changes in pumpage, together with the sometimes great variation in the strength of the individual drums of chloride of lime, has at times been a source of difficulty in the application of the treatment. This difficulty was greatest at the time when it was thought that 0.8 parts per million of chlorine was necessary. It is now found that from 0.5 to 0.7 parts is sufficient. Any amount in excess of 0.8 parts produces during cold weather objectionable tastes and odors.

In Jersey City, where the first practical tests of the treatment were made, it was found that 0.35 parts of chlorine per million was sufficient; this amount was used also at Cincinnati. In the Croton supply of New York 0.5 parts was required and in the Bronx supply 0.6 parts.

Compressed chlorine, liquefied under pressure, is now on the market sold in 100 lb. cylinders and can be had at about 8 cents per pound, about double the price of hypochlorite of lime as far as available chlorine is concerned. It has, however, many decided advantages over hypochlorite in that it is a pure and definite product which is absorbed by the water as a gas. It is easier to apply with regularity and its added cost is nullified by the fact that almost no labor is required in its application. No solution tanks are necessary and no lime sludge has to be disposed of. The only installation required for this treatment is a gas pressure-regulator with pressure gauges on either side of the regulator. The gas then passes through a series of hard rubber orifices and is absorbed in the flowing water. The only labor required is about 5 min. work to connect up a new 100-lb. tank once in 6 hours in the case of the Cleveland supply.

In regard to typhoid fever since the new 4-mile intake was installed in 1904 the death rates have been low. The year immediately following the installation of the new intake the typhoid death rate dropped from 48 to 15 per 100,000 and has averaged 16 for the 7 years that this intake has been in use. In spite of the low death rate there have been occasional times when for short periods the water appeared to be the source of slight infection and this infection occurred always in the early part of the year. It was to stamp out this source of risk that the sterilization of the supply was adopted.

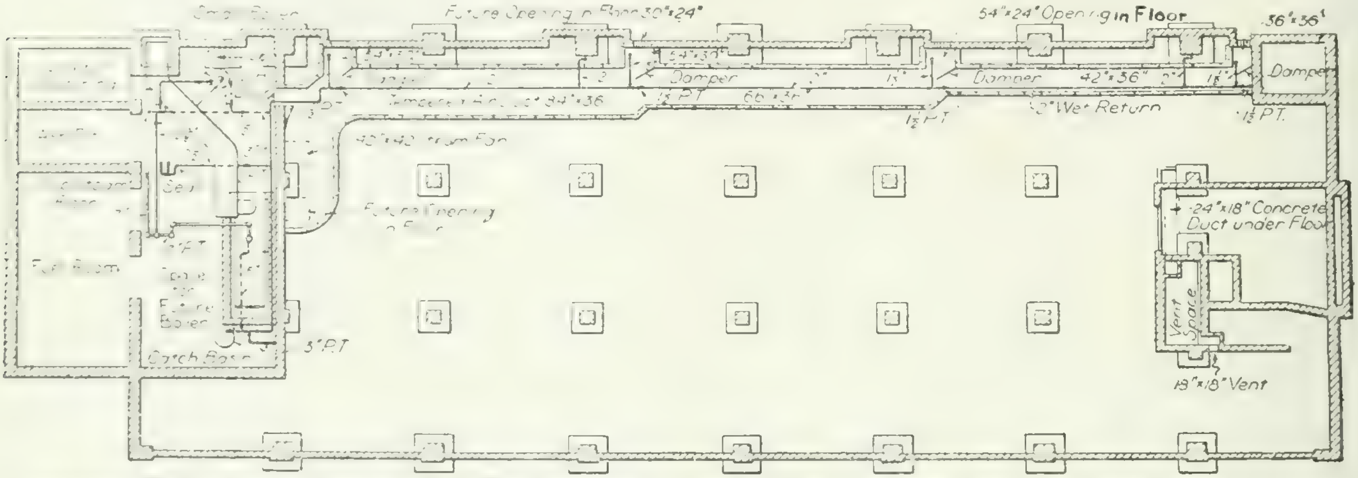
---

* Paper read before American Waterworks Association.

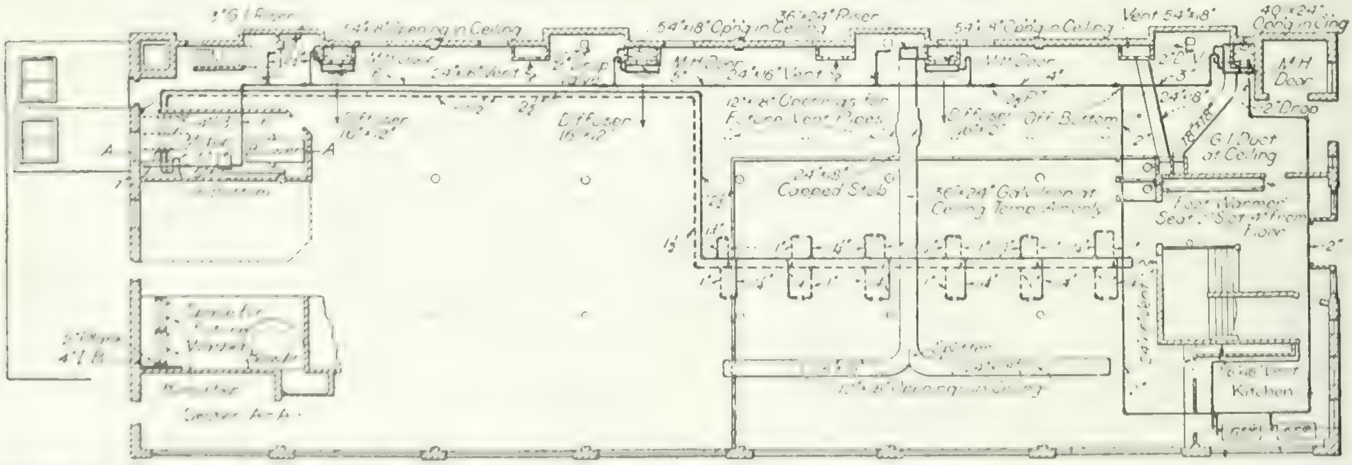
HEATING AND VENTILATION OF A FACTORY.*

By Samuel R. Lewis.

The object of this paper is to describe the heating and ventilating arrangements of the factory of the Defiance Tick Mitten Co., Toledo, O. The first floor is used for storage, packing, etc., while the second floor is occupied by about 250 operatives, nearly all women, who work at power sewing machines, pressing and finishing tables, etc. There are a number of steam-heated forms upon which the finished gloves and mittens are pressed. The desire of the owner was to provide an especially sanitary, light and attractive building, as he had learned by experience that these features had so great an influence on the attendance and efficiency of the labor that it was a good business investment as well as a function of good citizenship to provide them. The operatives are nearly all paid by piecework, [illegible]



Basement Plan, Showing Tempered Air Duct Supplied by Fan on First Floor and Leading to Flues Containing Heating Surface.



Basement Plan, Fan Heater Unit and Arrangement for Doubling the Capacity and the Steam and Air Distribution, Particularly for Second Floor.

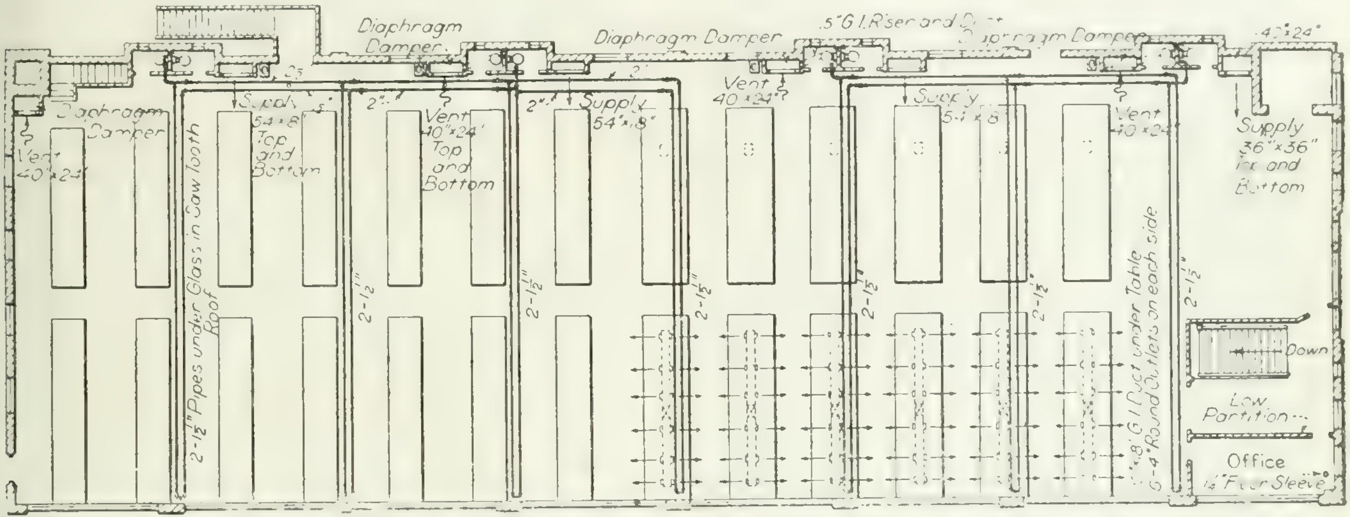
The building [illegible] construction, with [illegible]. The [illegible] are all in steel sash. The roof is of composition, laid on finished plank, and supported on steel trusses. The building is intended as the first of a group of a similar type, surrounding a central administration building and power plant. It is one-half of a future unit, and the division of the apparatus is such that the boiler, fan, coils, etc., for the other half may be added later on. Thus, the cost of the present plant was very little in excess of what it would have been had there been no thought of future additions. The boilers are placed in a sub-basement; one has capacity for all heating, ventilating and manufacturing requirements, and the other is provided for summer use for manufacturing and water heating. The principal manufacturing demand for steam is for heating the metallic forms used in pressing the finished product.

Fresh air is supplied through special steel casement sash, and is drawn through tempering coils and steam jet humidifiers to the supply fan. The steam supply to the tempering coils is controlled by a thermostat so that the tempered air is never cooler than about 60 deg., or warmer than that, unless the outside temperature is higher than 60 deg. The steam jets are controlled by a sensitive element which operates within a range of less than 5 per cent. at the point at which it is set (about 40 per cent. relative humidity). The supply fan delivers this conditioned fresh air through a concrete duct (which also serves as a return [illegible]) to the bases of the various flues. These flues have, near the ceiling of the first floor, individual coils, which have automatically controlled steam supply valves. The thermostats which operate these valves are of the gradual or stage operating type, and reduce or increase the amount of heated radiating surface as the temperature requirements dictate.

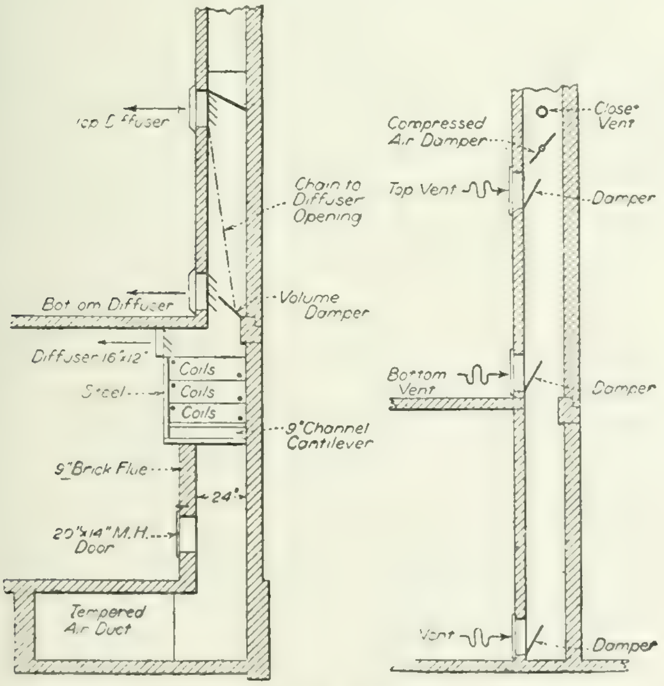
---

*Paper [illegible] Engineers, Detroit, Mich., [illegible]

The various supply flues discharge some air into the first floor, but their principal function is to serve the second floor, where a minimum of 30 cu. ft. of fresh air per occupant per minute is provided. When the building is being heated, the fresh warm air is discharged at a point about 10 feet from the floor through adjustable diffusers. It passes across the skylights and is forced against the almost continuous glass surface of the opposite wall. When the building is warm, however, the fresh air is discharged at the floor line through adjustable diffusers, directly at the lines of operatives. When heating, the exhaust air leaves the room at the floor, but when cooling or merely ventilating, the exhaust air leaves the room at the ceiling. To this end, each supply flue and each vent flue has two openings, with adjustable dampers in each.



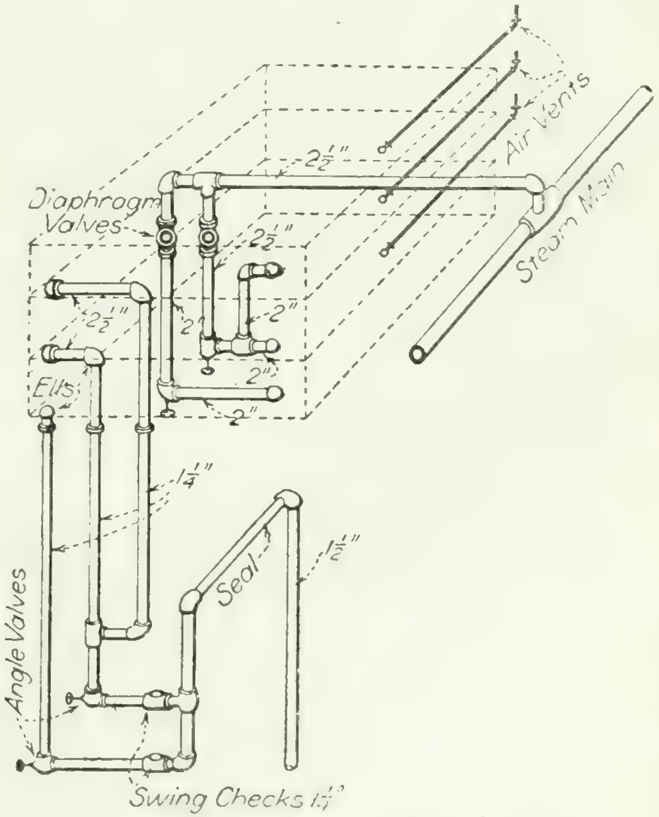
Second Floor Plan, Showing Air Supply Underneath Tables, Heating Coils Under the Sections of the Sawtooth Roof and Location of Fresh Air and Vent Flues.



Typical Fresh Air and Vent Flues.

In order that the operatives at the steam-heated forms may have the maximum of comfort, a 4-in. tempered air inlet at the floor, with an adjustable universal elbow and a blast gate for regulating the volume to each person, is provided. To offset possible cold drafts from the exposed roof or skylights, pipe coils under separate hand control are placed under each saw tooth glass area.

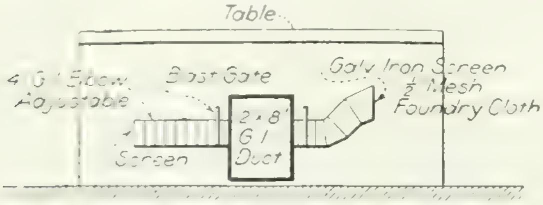
Many of the operatives walk some distance, and are liable to arrive at work with wet skirt bottoms and damp feet and ankles. A floor inlet would be objectionable from sanitary reasons, and so the concrete bench for drying purposes is provided and has proved quite effective. The seat is warm, about 100 deg., and through slots in its face a little above the floor, a strong blast of air is about 120 deg. maximum is delivered parallel with the floor. This air also warms the entrance hall and stairway.



Typical Connections to Heating Coils.

The escape of air from the building when it is unoccupied may be cut off by special dampers in the outlet flues, all being operated by compressed air by one switch valve in the fan room. All toilet fixtures are individually venti [illegible] openings in the bowls to separate vent flues.

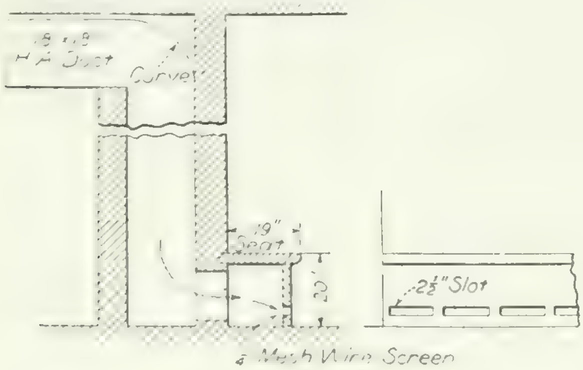
There is no direct radiation. The plant has been in operation through the severe weather of the past winter,



Adjustable Galvanized Duct Under Table.

and has proved entirely adequate. There have been no objectionable drafts, though many operatives sit at work directly alongside the exposed glass surface opposite the supply inlets. It has been found so far that the coils in the skylights are unnecessary.

The ventilation has been excellent. It has been found economical to keep the outlets closed and to rotate the air within the building, taking in no outside air when heating prior to occupancy. There has been increased comfort and no objectionable odor when the humidifying apparatus was in use, and when the temperature was kept down to 65 deg. There was no serious complaint of overheating with the temperature at 70 deg. and the humidity [illegible].



Air Warming Seat in Hall.

The absence of direct radiators contributes greatly to the ease of cleaning, and to the comfort and fuel consumption. With this system, the loss of heat through the glass and wall surface, for instance, is less, since the inside temperature is close to 70 deg. all over, while with direct radiators it would be close to 212 deg. opposite every unit. [illegible] of the building.

◆

CEMENT PRODUCTION.

[illegible]

THE RELATION OF ELECTRICAL ENGINEERING TO OTHER PROFESSIONS.*

By Cano Dunn.

On the wall of a great engineering library is the legend "Engineering is the art of organizing and directing men, and of controlling the forces and materials of Nature for the benefit of the human race."

This is broad and all-embracing, but other professions will find it hard successfully to quarrel with it.

While the immediate object of engineering is a material one, engineers draw from many different channels of human energy, such as generalship, commerce, psychology, mechanics, economics, to say nothing of chemistry and physics and many others, all under an interpretation insight and method that are best described by the term scientific.

It may be asked, Why could not a similar statement of embrasure or scope apply to medicine, the law, the army and other professions?

In part it could, but it is to engineering that it applies pre-eminently.

The subject matter of the older professions, the things about which they busy themselves, and the objects they seek to accomplish have changed relatively little in many centuries. The means have altered but the ends persist. They are approximately the same to-day as they have been throughout history and tradition.

With engineering it is different. There was no such profession a hundred and fifty years ago, and if I may a little anticipate my conclusion, there will be no such profession a hundred and fifty years hence in respect to a large part of what we now call engineering.

Such as it is, engineering is embracing an ever-growing horizon, and is including more and more of the activities of civilization.

When I say activities I refer to material ones and not to the whole of life itself. The human spirit is the greatest fact in the world, and art and literature that interpret it, the acts of our daily life and our personal relations that depend upon it, religion and the vast body of our social and political experience, that go to constitute life form undoubtedly a mass of activities, which are greater, in terms of consciousness, than the material activities which engineering can affect. In other words, the humanities which have been the same for ages can never be invaded by anything that merely rearranges our relations to the material world.

In the material world, however, which is at once the workshop and the throne, the glory and the limitation of the engineer, marvel has followed marvel and shall be followed by more marvels, for we are beginning to catch the tools' true play; beginning to see the vision of our dominion over the earth.

Whether it really is engineering to organize men, to predict the psychology of a fare-paying population, to win the endorsement of a labor union, to treble the yield of a farm by a microscope, all of which successes to-day are [illegible] depend upon the definition that we finally adopt.

It is startling to study the variety and importance of [illegible] showing the world how to increase greatly the lay of bricks, or the Agricultural Engineer working miracles with the soil that for ages farmers have struggled with, to the Civil Engineer establishing a kingdom and building the Panama Canal, we have instances in which the engineer is doing more and more of the world's work.

---

*[illegible] Annual Convention of the American Institute of Electrical Engineers, [illegible]

The history of this class of men so rapidly growing in numbers, so rapidly differentiating in function is almost a romance.

The Encyclopedia Brittanica names the middle of the eighteenth century—that is, 1750—as the time before which there were only Military Engineers—who constructed "engines" of war—and it adds that at about that time there began to arise a new class. Little did this new class realize the army it was leading down the industrial paths of time!

The "new class" has surpassed all bounds. From insignificance a hundred and fifty years ago it has increased almost incredibly in numbers and variety of specialization.

As a local indication, the Engineering Societies' Building in New York is the headquarters of fifty thousand engineers.

As another local indication, the American Institute of Electrical Engineers has in the last ten years increased six fold.

The growth in the variety of specialization has been almost as rapid as the increase in numbers.

Where there were only Military Engineers and the "new class" a hundred and fifty years ago, there are twenty-seven recognized varieties to-day.

Without mentioning all, they range from Civil through Mechanical, Electrical, Mining, Illuminating and Chemical, to Refrigerating, Industrial, Agricultural and Aeronautical. There is even a magazine with the title Human Engineering.

A large and increasing part of the capacity of our colleges and universities is devoted to the education of engineers.

Parts of the engineering curricula are borrowed for what used to be purely classical courses.

The metaphors of the speech of the day often have an engineering basis and—we have a McAndrews hymn.

The man in the street knows something about spark plugs, and many women understand the general principles of the telephone.

The social status of the engineer has emerged from that of a mechanic to one nearly as high as that of the clergyman, the physician or the lawyer.

Relatively recently there has been going on simultaneously with all this, however, hardly noticed, something else—a vast increase in so-called engineering work by men who are not engineers, and at the same time a large drawing off into executive, administrative, industrial, commercial, civic, educational, financial and even legal callings, of men of engineering training.

A history of segregation and disintegration seems to have begun to accompany a history of integration and building up.

For one to say to-day he is an engineer gives very little idea of what he actually does. It does not locate him in one of the twenty-seven recognized classes. It leaves is possible for the hearer to think of him as a "social engineer" or an "efficiency engineer" should he not look like a "civil engineer," but even if he did define himself and say he was an electrical engineer, the hearer would still not know whether he represented the last word on the loading of telephone circuits or his responsibility was to determine whether the great railroad terminals of Chicago should use a third rail or an overhead catenary.

If he should say "I am a teacher," "a physician," "a clergyman," "a lawyer," there would be a much more definite conception attaching to his answer.

There must be, therefore, in the title "engineer" something broader, something not included, or included to a lesser degree in the titles of the other professions or occupations.

A light is shed if we examine the popular definition that engineering is "educated common sense."

Can it be that unlike "physician," "lawyer," "teacher," the term "engineer" does not describe what a man does, but rather how he does it! A method rather than an occupation! It is even so; that is, essentially and with limitations I shall refer to later.

What then is this "method" that has given the engineer his ever broadening domain and brought all kinds of men and callings to his school? He can tell you at once. Here is where he is defined and where his fellows recognize him and each other though they come from the ends of the industrial earth as to diversity of actual occupation.

The method had its birth in Greece, though it was stifled almost to death by the tremendous philosophic, humanistic and artistic energies of the Hellenes. Later it was buried in Europe under the irruption of the barbarians.

The names of Thales, dear to our profession, with his "elektron," and of Aristotle and Archimedes, stand out as having done much for it—especially Archimedes—in spite of the humanistically polarized intellectual atmosphere in which they lived and which they contributed so gloriously to create.

But the Greeks made only a start. To quote an authority, their material thinking was largely based on what has proved to be a wrong method of procedure, the introspective and conjectural rather than the inductive and experimental. They investigated Nature by studying their own minds, by considering the meanings of words, rather than by studying things and recording phenomena. But they saw much of the light with all this.

Though absolutely dead for a thousand years in Europe, "the method" was kept alive during the middle ages in Arabia, although confused with magic, alchemy and algebra.

Then came Roger Bacon, Leonardo da Vinci and Copernicus, and science as we know it began to take shape.

Aristotle had sat down in his chamber and he wrote in a book, "A body twice as heavy as another of course falls twice as fast." Galileo released simultaneously from the top of the Leaning Tower a one pound and a one hundred-pound shot and they reached the earth together, before the eyes of the assembled University of Pisa.

But "the method" was repugnant to the University, and almost to a man they believed their Aristotle, sophistically explained away what they saw, and persecuted Galileo.

Descartes, Newton, Lagrange, Laplace, Francis Bacon connote to engineers the transcendent story, unless for electrical engineers there should be added Ampere, Faraday, Henry, Helmholtz, Kelvin.

The method of doing things that makes an engineer is, therefore, the applying to practical and utilitarian ends the principles and reasoning of science. Engineering is not science, for in science there is no place for the conception of utility. Truth is her sole criterion. In the exalted language of Professor Keyser, "Not in the ground of need, not in bent and painful toil but in the deep-centered play-instinct of the world Science has her origin and root; and her spirit, which is the spirit of genius in moments of elevation, is but a sublimated form of play, the austere and lofty analogue of the kitten playing with the entangled skein or of the eaglet sporting with the mountain winds."

Engineering is Science's handmaid following after her in honor and affection, but doing the practical chores of life.

concerned with the useful and the material; with costs and with expediency, and concerned with the humanities only in so far as they are an incident in some particular scheme of reality, and then objectively, if that may be said.

Her methods merely apply straight thinking to material problems for useful purposes.

Does this constitute a profession? No. Some day it will be the way almost everybody thinks instead of a body of specialists and then the difference between a doctor, for instance, and an engineer will be only in the things they busy themselves about; as is to-day the only difference between kinds of engineers.

The centre of education has been shifting rapidly recently—almost as rapidly as material well being has been increasing.

The application of science to living has marked an age as distinct as the age of the climax of Art in Greece.

The "new class" has been but a pioneer in sowing the seeds of scientific rationalization in a field the value of which was only dreamed of by Archimedes and not actually recognized until, as the Encyclopedia tells us, "about the middle of the eighteenth century," when the "new class" began to arise.

And now, as to the limits within which engineering is a method rather than an occupation.

There will always be engineers, for the methods of Science will constantly advance, and there will be needed continually, to interpret and transmit them to mankind, and to make the first applications of them to useful purposes, a class of men who, by instinct and taste, as well as by the possession of what I later shall call the dynamic component, find easier than other men—and consequently perform better the kind of scientific thinking, observation and action that characterize engineers to-day.

What these men will be busy about it is hardly safe to say, although it is probable the present great divisions of engineering will be more or less preserved. It seems certain that a large mass of knowledge that now is called engineering and forms the basis of many of the engineering specializations, will become general knowledge, and will be absorbed by the community, partly as a result of the shifting of the centre of education and partly through everyday familiarity, and the men possessing this knowledge will no longer be called engineers. They will be called farmers, let us say, in the case of the "Agricultural Engineer"—of course, a farmer of a very advanced kind compared to the earlier one.

But the centre of education will not always continue to shift. It is shifting now only because it has so long been [illegible].

It would be a calamity for it to shift too far, resulting in [illegible] and the utilities.

[illegible] engineering and the [illegible] themselves would languish instead of flourishing, for there would be lacking [illegible] component.

[illegible]

[illegible] personality, [illegible]

turies astray in the direction of their education and contributed to an underestimate of the importance of Science and the study of the laws of nature.

We must not go to the equally wrong other extreme.

So far I have said but little of electrical engineering. It must be brought in if for no other purpose than to justify our title. Although the article on "Engineering" in the Brittanica occupies only six inches of one column, it concludes with the following: "The last great new branch is electrical engineering, which touches the older branches at so many points that it has been said that all engineers must be electricians."

If engineering is a method of doing things, and electrical engineering tends to embrace all other branches, there is an implication that electrical engineering is the latest or most highly developed form of the method—the method that is the utilitarian application of the principles of Science to the material facts of life.

Such is unquestionably the case. Born scarcely more than twenty-five years ago, the "youngest branch," Electrical Engineering had the opportunity of striking its roots into the richest of scientific soils, free from prejudices, customs or traditions. It had no entangling alliances, no political laws to retard or encumber it. The field it preempted was the Terra Nova of Engineering, the New World of Applied Science.

Under the influence of those geniuses of Science, Volta, Faraday, Ampere, Ohm, Kelvin, Helmholtz, Maxwell, Oersted, Henry, and with the metric system for its cornerstone, there developed a comprehensive structure of thought and a related scheme of units. The latter are the admiration of the world for their simplicity, their convenience, their precision and their reproducibility. The scientific method as applying to all phenomena acquired its most perfect embodiment in the electric system and its relations.

But there is a philosophical debt that we electrical engineers owe our units. They school our minds. The ability to measure with precision difficult and complicated quantities enables clear thinking on them and renders reasoning about them possible that otherwise could not be attempted. To name a thing is to know it.

The wonderful electrical units are a fluent language that gives the widest opportunity to thought. By their character they educate our faculties of definition and relation.

They typify all quantitative thinking, not merely electrical.

They are the epitome, the last word of the great minds of our age, as to what the scientific method of thought is, in relation to the whole realm of matter and force.

Therefore, although the subject matter of electrical engineering is covering a wider and wider range—so wide as to be almost incongruous, the electrical method of thinking is applicable throughout. It is spreading far beyond.

As an electrical engineer, I even find myself thinking of the crowds passing in the streets in terms of amperes and volts, and of the fluctuations of the stock market in terms of current, inductance, capacity, resistance and resonance.

That which can impose form upon our thought enables us successfully to think of any kind of thing.

The forms of thought established for electrical engineering are so [illegible], so rich in detail, and so illuminating that engineering does not bound them.

They may be called the manifestation of Science in civilization, the best representation of the scientific method at work for utilitarian ends.

They prove that the profession of Electrical Engineering not only deals with single-phase motors, storage batteries, high-tension transmissions, turbo generators, coronas, carbon transmitters and commutation as an occupation, but that it also is a way of thinking, and as such is not an occupation, but the latest and most highly developed scientific method of solving all kinds of practical problems of matter and force, for the benefit of the human race.

◆

LARGE ROLLING LIFT BRIDGE.

One of the principal bridge building contracts of the year has just been placed by the Great Central Railway Company of England with Sir William Arrol and Company, Limited, of Glasgow, Scotland, for the construction of a large new railway and highway Scherzer Rolling Lift Bridge and approaches across the River Trent at Keadby, in Lincoln, England. The requirements of navigation at this point on the River Trent, just above where it enters into the River Humber, are quite severe and necessitated the most careful consideration in selection of the type of draw span, and the engineers of the railway company visited all of the important modern movable bridges in Great Britain and America before deciding upon the Scherzer type as best fulfilling the requirements of navigation and the very heavy traffic over the bridge.

The structure will be composed of two fixed approach spans in addition to the bascule span and the track girder span upon which the moving leaf rolls in its operation, on the well known simple Scherzer principle. The total length of steel work will be nearly 500 feet. Each span will have three trusses, the centre truss dividing the railway and roadway portions of the bridge deck. The railway section will have a width of 29 feet and the roadway 24 feet centre to centre of trusses.

The movable span of this bridge is of the Scherzer single leaf through type and as it will have a movable length of 160 feet and an extreme width of nearly 60 feet it will be one of the largest bascule bridges in the world. The machinery and power equipment designed for opening and closing the bridge in one minute is very simple and effective for so large and heavy a structure. The power will be electrically generated in a machinery house alongside the bridge and this current will actuate the motors which are placed on the rear end of the movable leaf. These motors are geared to the main operating shafts which drive pinions engaging with racks on independent fixed supports outside of the plane of the movable bridge trusses. This method of operation is one of the special features of the latest designs of Scherzer Rolling Lift Bridges, and reduces the machinery and power required to a minimum even in the largest and heaviest structures.

The substructure will consist of steel caissons carried to about 50 feet below the low water of ordinary spring tides and the masonry piers carrying the superstructure will be founded upon these caissons.

The entire bridge is designed in accordance with the latest practice in both foundations and steel structures to carry the heaviest main line traffic of the Great Central Railway between Doncaster, Grimsby and the large modern Immingham Docks on the Humber River.

Sir William Arrol and Company, Limited, will execute the work under the supervision of Mr. J. B. Ball, engineer-in-chief of the Great Central Railway Company, by whom the foundations and approach spans were designed. The Scherzer Rolling Lift Bridge Company, Chicago, Mr. Albert H. Scherzer, president and chief engineer, designed the superstructure, operating machinery and power equipment of the bascule span, and will maintain a general consulting engineering supervision over the manufacture and erection of that portion of the work in co-operation with Mr. Ball's staff.

LARGEST CLOCK IN CANADA.

The clock that claims the above title has recently been installed in the tower of the Vancouver Block on Granville Street, Vancouver, B.C. The four faces of this clock are each twenty-two feet in diameter. The glass contained in the dial weighs four tons, and is seven-eighths of an inch in thickness. The minute hands are eleven feet long and the hour hands about eight feet.

The clock is controlled by a master clock, which is situated on the ninth story of the building. This master clock is a 60-beat instrument, and transmits its time to the large clock in the tower. It is fitted with a pilot dial, which shows at all times the exact position of the hands in the tower piece. The master clock in turn receives its time through a synchronizing attachment, which delivers McGill observatory time once every minute, thereby assuring accuracy.

Machinery for operating this huge timepiece is all set in the clock tower. It consists in the main of a motor, which propels the hands. This motor is controlled by a magnet attachment, which only permits it to run for a period of fifteen seconds, this being the time required for the large hand to travel one-sixtieth part of the circumference of the dial. Thus the hands are still for forty-five out of every sixty seconds.

The current for running the clock is generated by a small dynamo, which is driven from the electric light mains. The energy from the dynamo is stored in accumulators.

These batteries are of sufficient capacity to run the clock for one week if the ordinary sources of current derived from the lighting mains were to fail. In case the storage batteries were to be put out of commission the generator would drive the clock direct.

Every point of friction in the clock—from the motor to the crown gear and hands—is fitted with ball bearings. The clock can be set either from the office of the superintendent or in the tower.

The hour marks are a single bar ten inches wide and about four feet long. They will be left blank, no numerals being painted on them. The dial is constructed of structural steel, and not, as in most of the older clocks of the country, of cast-iron. The minute divisions of the clock are five and one-half inches wide and about one foot long. The hands are made of aluminum.

The clock was erected by the Standard Electric Time Company, of San Francisco, at a cost of more than $10,000.

◆

TRACK SINKAGE NEAR VANCOUVER, B.C.

The tracks of the Great Northern Railway a few miles south of Vancouver have been the cause of considerable trouble to the trainmen for several days. We recently announced the fact that these tracks were sinking in a bog-hole. Since then we have obtained additional information.

Ardley Station, the scene of the trouble, lies right in the heart of the Still Creek district. Still Creek is really a flat sump for the drainage of the district lying between Hastings Townsite and Burnaby Lake. The land it drains has very little fall, and the creek spreads out into wide areas of muskeg. At Ardley both the Great Northern and the British Columbia Electric Railway Burnaby line tracks run close together.

Every day for two weeks trainloads of dirt, brush and rocks have been piled into the hole in the hope that bottom and a firm foundation would finally be reached. Fifty cars of material per day have been put into the sink without any apparent beneficial effect.

TESTS OF BRICK.

The Canadian Department of Mines recently ordered an investigation of the clay and shale deposits of the Western Provinces, and while this was in preparation sixteen lots of bricks were shipped to Prof. A. Macphail, of the School of Mining, Kingston, Ont.

Each lot of bricks contained about twelve specimens; the lots, on receipt, were designated by letters (A to P), and each brick in this division again designated by a number (1 to 12). The following list gives the series letter, the locality from which the bricks were obtained, and the kind of brick:—

List of Bricks Collected for Testing.

Series. Manitoba.

E.	Alsip Brick and Tile Co., Winnipeg......	Soft-mud.
B.	The Stephens Brick Co., Portage la Prairie	Soft-mud.
C.	A. Snyder & Co., Gilbert Plains....... ...	Soft-mud.
D.	Leary's Pressed Brick Works, Leary Siding	Dry-press.

P.	John Coughlan & Sons, New Westminster	Soft-mud.

Tests.

Eight separate tests were conducted on the bricks of each series, and these tests are indicated by the letters (a to h). Here follow the specifications under which the tests were made:—

a. Place six thoroughly dried bricks in water to the depth of one inch, and leave them covered over for forty-eight hours. Weigh before and after this partial immersion, to calculate the percentage of absorption in terms of the original dry weight.

b. Test six **dry** bricks flatwise on supports seven inches apart, to determine their transverse strength.

c. Take the six bricks from the absorption test, soaking them some more if they have dried out, and determine the transverse strength of these wet ones.

d. Take one-half of each brick from Series b and determine its crushing strength set flatwise.

e. Take the other half of each of the bricks from b, and determine their crushing strength when set on edge.

f. Take one-half of each of the bricks from Series c, and determine their crushing strength when set on edge.

g. Take the other half of each brick from c, soak it [illegible] in water, and then subject to a temperature of not less than 15° F. for five hours, all faces of the samples being exposed. The bricks are then thawed [illegible] for one hour. This is to be repeated twenty times.

h. Determine the crushing strength on edge of the [illegible] after they have been through the [illegible] test.

With regard to the crushing test, the sides or edges of the brick in contact with the machine are to be made flat and parallel with plaster of paris. The opposite sides should be exactly parallel. The testing machine should be equipped with spherical bearing blocks.

Table I.

Series No.	Test a. Per cent absorption.	Test b. Transverse (dry)		Test c. Transverse (wet)		Test d. Crushing flat (dry)	Test e. Crushing on edge (dry)	Test f. Crushing on edge (wet)	Test h. Crushing on edge (dry) after freezing.

H	19·2	825	384	920	428	1692	1868	1628	2027
I	22·2	702	365	617	320	1298	1512	1282	1400
J	24·1	774	337	797	343	1220	1492	1502	1989
K	15·8	640	298	506	237	1320	1494	1310	1732
L	14·4	672	313	598	278	2242	1660	1948	1950
M	15·3	657	267	612	249	2343	1364	1513	1503
N	15·8	808	329	662	270	2420	1640	1296	1190
O	20·8	972	467	983	471	1869	1950	2658	1990
P	14·4	2008	972	1618	776	5242	5735	4028	5115

The results of the various tests are given in Table I., and are the averages of the observations on six bricks in all cases, except those in test "h," where the bricks which were destroyed in the freezing test were, of course, not given.

The modulus of rupture was calculated from the transverse test by the usual formula:—

$$S = \frac{3}{2} \frac{W l}{b d^2}$$

Where W is breaking load at centre in pounds, l is the span, b is the breadth of the brick, and d the depth.

In the case of bricks which had a frog, the area of the frog was deducted from the gross area when the bricks were tested for compression strength on edge.

Table II. Bricks were frozen and thawed twenty times as specified. In the column "Remarks," the numerals denote the number of times the brick was frozen before disintegration began to set in.

◆

RAILWAY DEVELOPMENT IN THE KOOTENAY

The announcement of the West Kootenay Power & Light Company, that it will install a third unit in its main plant at Upper Bonnington Falls, below Nelson, to be in a position to furnish electric power to the Canadian Pacific Railway when the latter electrifies its Rossland branch, is one of the numerous ways in which the construction activity of the railway company in the Kootenay is reflected. The plant is hydraulically developed for 32,000 horse-power, and electrically developed for 16,000 horse-power at present. The change to electricity for motive power on the Rossland branch, it is generally believed, is to be the first step in the application of this agent throughout the system in the mountains.

Preceding this change, for the last two years the Canadian Pacific Railway has been steadily improving the whole system tributary to the Crow's Nest branch, and shortly the through route portions will be of a standard equal to the main line.

The construction in the Slocan, which is to extend the Slocan system over the summit and down to Kootenay Lake, is nearing completion. On the Kootenay Lake section, the old Kaslo & Slocan line of the Great Northern has been re-opened temporarily as a narrow gauge line, to take in supplies and bring out ore. Next season the entire system will be standard gauge. The Canadian Pacific Railway, it is just announced, will construct ore docks at Kalso, the port of that region, and the silver-lead ore of the section will be conveyed in barges to Nelson, where it will be transferred to rail for transport to the Trail smelter.

The steel hull for the new Kootenay Lake steamer has arrived from the yards of the Polson Iron Works, Toronto, in five cars, and 150 men are now at work in the Nelson yards on this $200,000 boat, which next year will take its place in the through service.

Overshadowing any of these evidences of the railway company's intentions with regard to this territory is the rate at which the short line is being pushed through toward the Coast. In eight months, at the present rate of construction, the extension of the present Boundary branch, which now is operated to Midway, will be completed to Penticton, on Okanagan Lake. In thirteen months or less there will be connection with Merritt, the present terminus of the Nicola branch from the main line. On the date that that connection is established, the through Crow's Nest route will be diverted at Nelson to the Boundary branch, when a direct train service between Nelson and Vancouver will be inaugurated. This will be the third route between these termini, and will be much shorter than either the Arrow Lakes route or the Great Northern route.

This revolutionary programme requires practically but a year for its completion, and in all essentials the new Crow's Nest through route will be in existence and operation. When the Lethbridge-Weyburn cut-off on the prairie, and the Merritt-Hope cut-off near the Coast range are completed, the Crow's Nest route will originate at Winnipeg, and it will be at least a co-ordinate route with the main line.

REPORT OF CALGARY MUNICIPAL STREET RAILWAY.

The net profits of the Calgary Municipal Street Railway system for the fiscal year ending June 30 last were $107,253.49. This and other interesting facts are set forth in the annual report of Thomas H. McCauley, superintendent of the street railways, to the Minister of Railways.

The net profits for 1911 were $87,206.09, showing an increase in the net profits for 1912 of $20,047.40.

The total operating expenses for the year ending June 30, 1912, were $282,600.56, and the total gross revenue for the period was $479,240.24, or the ratio of operating expenses to gross revenue was 59.44.

Salaries paid to employes totalled $172,521 for 1912, as against $76,686.85 for 1911. The total length of main track for 1912 was 52 miles as compared with 36½ miles for 1911.

The report in detail is as follows:—

	1912. Cost June 30th.	1911. Cost June 30th.
Engineering	$ 4,055.40	$ 4,055.40
Track construction	901,622.29	627,320.71
Line construction	94,551.77	62,330.46
Buildings	24,317.85	15,592.55
Shop, tools and machinery	2,145.65

◆

MONTREAL COMPANIES

The announcement has been made that the Quebec Railway, Light, Heat and Power Company will show a satisfactory increase in earnings in its annual financial report. It is stated, apparently in a semi-official manner, that the following will be the result:—

	1911.	1912.	Increase or decrease.
Gross earnings	$1,280,126	$1,565,000	+ $284,874
Operating expenses	661,907	733,000	+ 71,093
Net earnings	618,219	832,000	+ 213,781
Fixed charges and div.	581,319	620,000	38,681
Organization expenses	10,681	....	....
Extraordinary income	111,100	.	....
Surplus	[illegible]	212,000	.

As the capital stock of the company is $10,000,000 it will be seen that the surplus indicated is equal to 2⅛%. The above comparison fails to indicate the real improvement in the Quebec Railway, Light, Heat and Power Company. Included in the extraordinary income mentioned above for last year was $100,000 which was not earned by the company itself but by its subsidiaries, previous to July 1st, 1910, at which date the amalgamated company began business. In reality, therefore, the surplus of $62,328 might have been shown as a deficit of $26,991 on the year's business, being $37,672, less the organization expenses of $10,681.

The situation, therefore, is that instead of going practically $27,000 behind, as was the case last year, the company will be $213,781 ahead.

The dividend payments amounted practically to $100,000 per quarter. As the dividend was passed some few months ago, these payments will no longer be necessary. Two of these payments were made during the past year, so that had the company not made them, the surplus would have been increased by about $200,000. Assuming that above figures are correct, it is manifest that the situation in Quebec Railway, Light, Heat and Power has improved.

◆

POWER POSSIBILITIES AT CARILLON.

Another new power development in the vicinity of Montreal is being discussed. The site of the proposed development is Carillon, about sixty miles up the Ottawa River from Montreal. Carillon is the terminal point of the Ottawa River Navigation Company. Navigation is uninterrupted, save for canals and locks, from Montreal to Carillon. Here, however, passengers westward bound are compelled to leave the boat and take the train, the cause of the interruption being the rapids or falls of Carillon, and the famous old dam. This dam took some five years to build and cost some $3,000,000.

For many years, a great deal of power has been going to waste at this point. Estimates on the amount of power vary very greatly, some placing it as high as 150,000 horsepower. This estimate, however, is not generally credited. In the estimate made for the commission of conservation, the Carillon rapids are credited with being able to supply 26,000 horsepower from the present possible head of 13.5 feet, but it is added that with the river canalized, and with the water control which is included in the Georgian Bay canal scheme, a head of 40 feet with a total of 200,000 horsepower can be developed.

Mr. Henry Myles, formerly president of the Montreal board of trade, is at the head of the company which proposes to develop the falls. It is claimed that there will be no difficulty in getting the capital, and that the power can be readily sold in the city of Montreal.

◆

NEW FORESTRY ENGINEERS.

At the University of Toronto nine men received the degree of Bachelor of Science in Forestry, and three others are eligible for the degree after passing supplmental examinations. The recipients of the degree were Messrs. R. M. Brown, F. G. Edgar, E. J. Finlayson, H. S. Irwin, R. G. Lewis, C. McFayden, E. C. Manning, W. L. Scandrett and W. J. Vandusen. All of these entered the employ of the Dominion Forest Service. Their present disposition is as follows: R. M. Brown, forest assistant Brazeau forest reserve, Edmonton, Alta.; F. G. Edgar, for assistant Bow River reserve, Calgary, Alta.; E. J. Finlayson, Inspector of Fire Ranging; R. G. Lewis, head office, Ottawa; C. McFayden, forest assistant, Crow's Nest forest reserve, Pincher Creek; W. L. Scandrett, in charge of forest survey party near the Porcupine forest reserve No. 2, Saskatchewan; W. J. Vandusen, supervisor, Crow's Nest forest reserve, Pincher Creek, Alta. Mr. Irwin has since joined the British Columbia forest service.

◆

The State of Wisconsin is overhauling its forest laws, and at the last session no fewer than eight bills were passed dealing with different aspects of the forestry question.

◆

PERSONAL.

J. V. DILLABOUGH, B.Sc., D.L.S., has been appointed office engineer of the Hudson Bay Railway, Fort Garry Court Winnipeg.

MR. J. D. GILMOUR, late of the C.P.R, forestry department, has been appointed supervisor of the Brazeau forest reserve, with headquarters at Edmonton.

DR. A. S. ESTEY, medical health officer of Calgary, Alberta, has tendered his resignation to the mayor and council of that city.

MR. M. J. K. ALLEN, who a few weeks ago resigned as city engineer of Regina, has become manager of the Ontario Asphaltic Concrete Paving Company, which company has just secured contracts for 30,000 square yards of pavement in North Toronto.

MR. G. SKIFF GRIMMER, of the U. of N.B. class of 1908, is engineer and forester for the American Canning Company, near St. Andrews, N.B. The company has a considerable tract of timber and will grow timber for box shooks.

MR. JOHN DUDGEON, of F. S. Dudgeon, Limited, London, England, called at *The Canadian Engineer* office this week on his way home, after seeing to the installation of one of their excavators at the plant of the Tofield Coal Co., Tofield, Alta.

MR. HARRY HARTWELL, who for the past year has been acting as resident engineer on the Sooke Lake waterworks development scheme, has severed his connection with the firm of Messrs. Sanderson & Porter, which is supervising that work, and will hereafter be identified with the F. S. Pearson Engineering Corporation, of New York city.

MR. R. G. LEWIS, B.Sc.F., has been for some time engaged in the compilation of the forest products bulletins for 1911 at the head office of the Forestry Branch at Ottawa. He will leave shortly for the Maritime Provinces, in connection with the compilation of the study of the wood-using industries of the Maritime Provinces, on which the Forestry Branch is entering.

MR. SAMUEL HALE, the new general manager of Algoma Steel, is at present vice-president and general manager of the Wisconsin Steel Company. He will take up his position about October 1st. Mr. Hale is 43 years old, and was born in Chicago. He started in the steel business in 1893 with the Illinois Steel Company, and served with them in various capacities until 1899, when he was appointed assistant general superintendent. He was subsequently associated with the operations of the International Harvester Company, whose steel properties were organized into the Wisconsin Steel Company, of which, as stated, Mr. Hale was made vice-president in charge of the operations. With these he has been associated for the last ten years.

MR. F. H. McGUIGAN, who was awarded the contract for constructing the new filteration plant for the city of Montreal, has notified the Board of Control that he desires to hand over his contracts to his chief engineer, Mr. Norman McLeod. The controllers were notified recently that owing to ill-health it was impossible for Mr. McGuigan to continue the contract, and asking that all of the contracts be transferred. Mayor Lavallee has stated that the controllers have accepted the principle of the transfer.

COMING MEETINGS.

CANADIAN GAS ASSOCIATION.—Fifth annual convention will be held in Toronto, August 24th to Sept 9th, 1912, during the Exhibition. Sec'y-Treasurer, John Keillor, Hamilton, Ont.

THE UNION OF CANADIAN MUNICIPALITIES.—August 27, 28 and 29. Meeting at City Hall, Windsor, Ont. Hon. Secretary-Treasurer, W. D. Lighthall, K.C.

CANADIAN FORESTRY ASSOCIATION.—Convention will be held in Victoria, B.C., Sept. 4th-6th. Secy., James Lawler, Canadian Building, Ottawa.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Second Annual Meeting to be held in Toronto, Sept. 16, 17 and 18.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Annual Assembly will be held at Ottawa, in the Public Library, on 7th October, 1912. Hon. Sec'y, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

EIGHTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.—Opening Meeting, Washington, D.C., September 4th, 1912. Other meetings, Business and Scientific, in New York, beginning Friday, September 6th, 1912 and ending September 13th, 1912. Secretary, Bernhard G. Hesse, Ph. D., 25 Broad Street, New York City.

INTERNATIONAL ASSOCIATION FOR TESTING MATERIALS.—Sixth Congress will be held in the Engineering Societies Building, 29 West Thirty-ninth Street, New York. Sept. 2 7, 1912 Secretary, H. F. J. Porter, 29 West Thirty-ninth Street, New York.

ILLUMINATING ENGINEERING SOCIETY.—Sixth Annual Convention to be held at Hotel Clifton, Niagra Falls, Ont., Sept. 16-19, 1912. Secretary, Preston S. Millar, 29 West Thirty-ninth Street, New York.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Ninth Annual Convention will be held in Cincinnati, December 3, 4, 5 and 6, 1912. The Secretary, 150 Nassau St., New York.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memorial Museum, Ottawa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE · Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

[illegible] BRANCH—Chairman, C. E. Cartwright; Secretary, Mr. Hugh B. [illegible], Vancouver, B.C. Headquarters, McGill [illegible]

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; [illegible]

[illegible] BRANCH—Chairman, J. A. [illegible]; Secretary, E. E. Brydone-[illegible] [illegible] October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

[illegible] ASSOCIATION.—President, [illegible]

[illegible] ASSOCIATION OF RURAL MUNICIPALITIES—[illegible]

[illegible]

[illegible]

[illegible]

[illegible]

[illegible]

[illegible]

[illegible] OF ALBERTA MUNICIPALITIES.—[illegible]

[illegible] MANITOBA MUNICIPALITIES.—[illegible]

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President, J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Jas. Anderson, Gen. Mgr., Sandwich, Windsor and Amherst Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, A. F. Wickson; Toronto. Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer [illegible], Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, [illegible] Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box [illegible], Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, P.O. Box [illegible], Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only, unless otherwise noted, at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close		Noted in issue of
8-31	—Trenching and Backfilling, Edmonton, Alta. (S.)	8-8

(Canora specifications are also on file at the office of The Canadian Engineer, Rooms 617-628, Transportation Building, Montreal.)

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

TENDERS.

Calgary, Alta.—Tenders for the construction of three reinforced concrete bridges aggregating some 25 spans across the Bow and Elbow Rivers within the city limits of Calgary, will be received until August 31st, 1912. Plans, etc., can be obtained from the office of the City Engineer. J. M. Miller, city clerk.

Dauphin, Man.—The Rural Municipality of Dauphin, Man., are calling for tenders for the superstructures of four highway bridges. Specifications and other information can be obtained from J. A. Gorby, Secretary-Treasurer, Box 330, Dauphin, Man. (See advt. in The Canadian Engineer.)

Edmonds, B.C.—Tenders for the erection of a timber bridge 50 feet span, including piling and abutment, will be received until noon of August 24th, 1912. Particulars and specifications may be had at the Engineer's office, Edmonds, B.C. Wm. Griffiths, Comptroller, Municipal Hall, Edmonds.

Edmonton, Alta.—Tenders addressed to L. B. Elliot, district engineer, office of the district engineer, Edmonton, and endorsed "Tender for the purchase of material at Goose Islands, Alta.," will be received until September 4th, 1912.

Moncton, N.B.—Tenders for laying water mains in the city of Moncton, according to plans and specifications, which may be seen at the city engineer's office, and where forms of tender may be obtained, will be received until noon of September 1st, 1912. J. Edington, city engineer.

Montreal, Que.—Tenders for moving the Queen Victoria monument on Victoria Square from its present position to the centre of the square, will be received by the Board of Commissioners, City Hall, until noon of August 29th, 1912. Full information may be obtained in the office of the Engineer Superintendent of the Road Department. L. N. Senecal, secretary, Board of Commissioners, City Hall, Montreal.

Ottawa, Ont.—Tenders addressed to L. K. Jones, Assistant Deputy Minister and Secretary, Department of Railways and Canals, Ottawa, will be received until the 12th of September, 1912, for the construction of the section of the Hudson Bay Railway from Split Lake Junction to the Hudson Bay Terminus. Plans, etc., can be seen at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Chief Engineer of the Hudson Bay Railway, Winnipeg. (See advt. in The Canadian Engineer).

Ottawa, Ont.—Tenders addressed to R. C. Desrochers, Secretary, Department of Public Works, Ottawa, will be received until August 26th, 1912, for interior fittings, post office, at Port Hope, Ont. Plans and specifications to be seen on application to Mr. James Curtis, caretaker, public building, Port Hope, Ont., Mr. T. A. Hastings, Clerk of Works, Postal Station "F," Toronto, and at the Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders addressed to R. C. Desrochers, Secretary, Department of Public Works, Ottawa, will be received until August 28th, 1912, for the construction of a wharf at Upper Maugerville, Sunbury County, N.B. Plans, etc., can be obtained at the Department, and at the offices of J. K. Scammell, Esq., District Engineer, St. John, N.B., and on application to the Postmaster at Upper Maugerville, N.B.

Ottawa, Ont.—Tenders addressed to L. K. Jones, Assistant Deputy-Minister and Secretary, Department of Railways and Canals, Ottawa, will be received until noon of September 14th, 1912, for wall at Smith's Falls. Port Arthur, Ont.—The Department of Public Works, Ottawa, has arranged with W. E. Phen and Co., contractors, [illegible] also.

St. John, N.B.—Contracts for the new automobile factory [illegible]

Tarvia
Preserves Roads
Prevents Dust–

Main Street, Wolfville, N.S., Constructed with Tarvia X.

Millions of Yards Treated

FOR a hundred years macadam roads have been standard. The motor driven vehicle, however, added a new destructive element to road wear that macadam had not provided for. A stronger binder than stone dust was found necessary to hold the road together under this traffic.

The new conditions brought forth a variety of bituminous binders. Of these Tarvia, manufactured from refined coal tars, was the first to be used and is now standard for this purpose.

Tarvia is made in three grades—"Tarvia X" for road and pavement construction. "Tarvia A" for hot surface application, and "Tarvia B," applied cold, for dust prevention and road preservation.

Millions of yards of macadam have been successfully tarviated in all parts of the country. The use of Tarvia waterproofs the macadam, prevents its disintegration, keeps down the dust and gives a surface that is smooth, well bonded and automobile-proof.

Towns and cities which have used Tarvia for a number of years are proud of their roads and pavements, while the records show that its use has been most economical—the saving in maintenance expenses having generally more than paid for the cost of the treatment.

Booklet showing roads in various parts of the country treated with Tarvia and giving details of the process mailed free on request.

THE PATERSON MANUFACTURING COMPANY, LIMITED
